Document Title	System Template
Document Owner	AUTOSAR
Document Responsibility	AUTOSAR
Document Identification No	63

Document Status	published
Part of AUTOSAR Standard	Classic Platform
Part of Standard Release	R24-11

Document Change History

Date	Release	Changed by	Description
2024-11-27	R24-11	AUTOSAR Release Management	• Enhanced PduR Fanout chapters • Added imposition times to constraints • Introduced J1939ProtectedIPdu • Reworked Ethernet Switch configuration: – Added Frame preemption support – Reworked CouplingPortTrafficClassAssignment
2023-11-23	R23-11	AUTOSAR Release Management	• Added support for DDS configuration • Added support for Firewall configuration • Added support for ACL checks • Added support for modeling of IEEE1722Tp streams and Ethernet Switch Filtering and Policing
2022-11-24	R22-11	AUTOSAR Release Management	• Added support for MACsec • Added support for Can XL • Clarification of usage of transfer property for signal groups and group signals • Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation

▽

△

2021-11-25	R21-11	AUTOSAR Release Management	• Rework of Log and Trace model • Rework of TLS modeling using IANA Parameters • Introduction of Affinity Constraints • Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation
2020-11-30	R20-11	AUTOSAR Release Management	• Added support for 10-BASE-T1S • Added support for Software Clusters • Improved RTE Fan-in and RTE Fan-out description • Introduced modeling approach for Service Discovery Service Interfaces on VFB level
2019-11-28	R19-11	AUTOSAR Release Management	• Rework of Ethernet communication model • Added support for Signal-To-Service Translation • Added support for IPsec configuration • Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation • Changed Document Status from Final to published
2018-10-31	4.4.0	AUTOSAR Release Management	• Added support for BusMirorring • Reworked the modeling of LinSlaves • Introduced Crypto Infrastructure for SecuredIPdu • Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation
2017-12-08	4.3.1	AUTOSAR Release Management	• Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation

▽

△

2016-11-30	4.3.0	AUTOSAR Release Management	• Added support for new E2E Profiles 7, 11 and 22 • Improved configuration of Ethernet Switch Ports • Introduced Security Profiles • Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation
2015-07-31	4.2.2	AUTOSAR Release Management	• Minor corrections / clarifications / editorial changes; For details please refer to the ChangeDocumentation
2014-10-31	4.2.1	AUTOSAR Release Management	• Introduction of data transformation • Introduction of SecuredIPdu • Introduction of Switch Configuration • Introduction of Global Time Synchronization • Improved support for CanFD • Minor corrections / clarifications / editorial changes; For details please refer to the BWCStatement
2014-03-31	4.1.3	AUTOSAR Release Management	• Various fixes and clarifications
2013-10-31	4.1.2	AUTOSAR Release Management	• Set CanNmCluster.nmChannelActive, FlexrayArTpChannel.timeFrIf and FlexrayArTpChannel.maxFrIf to deprecated • Added SoAd Pdu Collection attributes to SocketConnection • Added SoAdRouting-Group.eventGroupControlType • Introduced SocketAddress.multicastConnector • Clarified usage of ISignal.dataTypePolicy • Described the handling of ComSpecs during flattening ▽

▽

△

			△ • Introduced new Pdu types: GeneralPurposePdu and GeneralPurposeIPdu
			• Made RootSwCompositionPrototype.calibrationParameterValueSet "atpSplitable" • Made RootSwCompositionPrototype.flatMap "atpSplitable" • Added new Ethernet addressing attributes to SocketConnection to help to derive the Ecu Configurations for the Server and the Clients
2013-03-15	4.1.1	AUTOSAR Administration	• Added support for remote activation of RunnableEntitys • Added support VLANs and Service Discovery • Reworked the SoAd configuration • Introduced SenderReceiverCompositeElementToSignalMapping and ClientServerToSignalMapping • Added support for CAN FD • Reworked the J1939 TP configuration • Clarification of the usage of swDataDefProps on ISignals and SystemSignals • Added support for Complex Drivers in the Topology • Updated IPduM to allow only static part reception • Added LinSlaveConfig class to the LinMaster • Clarified meaning of PduToFrameMapping.startPosition

▽

△

2011-12-22	4.0.3	AUTOSAR Administration	• Added support for Partial Networking • Added support for Complex Drivers • Added support for new COM transfer properties • Added support for transmission mode switch via Com_SwitchIpduTxMode COM API • Added support for treating byte arrays with primitive type mapping • Added support for partial routing in signal gateways • Added support for FlexRay AUTOSAR TP • Added rules for creation of Pdu Triggerings and Pdu Ports • Explained the general approach of bit counting
2009-12-18	4.0.1	AUTOSAR Administration	• updated System class category names • Changed specification of PduLength parameter from bits to bytes • Made Flexray channel specific attributes optional • Clarified the usage of EcuPorts in System Extract/Ecu Extract • Allowed to define sending and receiving connections to EcuPorts for NmPdus, XcpPdus • Aligned FrTP model to AUTOSAR FrTp SWS • Replaced ComProcessingPeriod by three timebase parameters • Reworked E2E protection of selected I-PDUs • Corrected AssignFrameIdRange configuration in LIN model ▽

▽

△

			△ • Clarified the routing of ISignalGroups in the Signal Gateway • Extended the enumeration "TransferPropertyEnum" with the element "triggeredOnChange" • Added a subchapter to the appendix about special use cases that are supported by the System Template • Reworked SenderReceiverToSignalGroupMapping and ClientServerToSignalGroupMapping • Changed multiplicity between System and SystemMapping from 1 to 0..1.
2009-12-04	3.1.4	AUTOSAR Administration	• Implemented support for LIN 2.1 • Implemented support for Network Management (FlexRayNm, CanNm, LinNm, UdpNm) • adapted IPdu Multiplexer model to ASAM Fibex 3.1 • Reworked "ECU Extract" chapter • Introduced "System Extract" • Introduced EndToEndProtection for ISignalIPdus • Reworked "Transport Layer" chapter • Implemented Variant Handling concept • Implemented Documentation support concept • Implemented support for J1939 communication • Implemented support for TTCan • Implemented support for for TCP/IP and DoIP. • Introduced Pdu Counter and Pdu Replication ▽

▽

△

			△ • Implemented VMM/AMM concept • Introduced low-level routing of NPdu's • Implemented support for dynamic signals • Introduced PdurIPduGroups
2009-02-04	3.1.2	AUTOSAR Administration	• Clarified semantics of Data Mappings • Added inheritance from Identifiable to PduToFrameMapping • Added "FlexRayChannelName" attribute to FlexRayPhysicalChannel element.
2008-08-13	3.1.1	AUTOSAR Administration	• Added the boolean attribute "payloadPreambleIndicator" to the "FlexrayFrameTriggering". • Added extension that allows the assignment of IPduGroups to ECUs. • Added missing reference from "ClientServerComposite-TypeMapping" to "ArgumentPrototype" • Alignment with AUTOSAR IPduM SWS
2008-02-01	3.0.2	AUTOSAR Administration	• Moved "canAddressingMode" attribute from "CanCluster" to the "CanFrameTriggering" element • Clarified the descriptions of several elements and attributes.
2007-12-21	3.0.1	AUTOSAR Administration	• Communication part reworked from scratch • Alignment with ECU Configuration • Added support for Transport Protocols • Major changes in Topology chapter after harmonisation with Fibex (removed complex Topologies) • Document meta information extended • Small layout adaptations made

▽

△

2006-11-28	2.1	AUTOSAR Administration	• Support for Signal Groups added. • Rework of the Topology Description • Introduction of PDUs. Description of the PDU Multiplexer, PDU Gateway. • FlexRay: multiple transmission of a frame within one communication cycle is supported now. • Removed the concept of Variant Descriptions (Properties) and CompToECUMappingConstraints relying on the property concept. • Split SwCompToEcuMapping in two classes in order to allow separation of SWC-to-ECU mapping and Implementation-to-SWC mapping. • Removed preliminary chapter on MOST as it is not part of the standard. • For all Instance References in the System Template added diagrams to the meta-model containing detailed representations of these references.
2005-05-31	1.0	AUTOSAR Administration	• Initial Release

1 Introduction

1.1 Methodology for Defining Formal Template

Figure 1.1 illustrates the overall methodology used to define formal templates. As is explained in the "Generic Structure Template" [1], it is important to separate a precise and concise model of the information that needs to be captured from the concrete XML-DTDs, XML-Schemas or other technology that is used to define the actual templates.

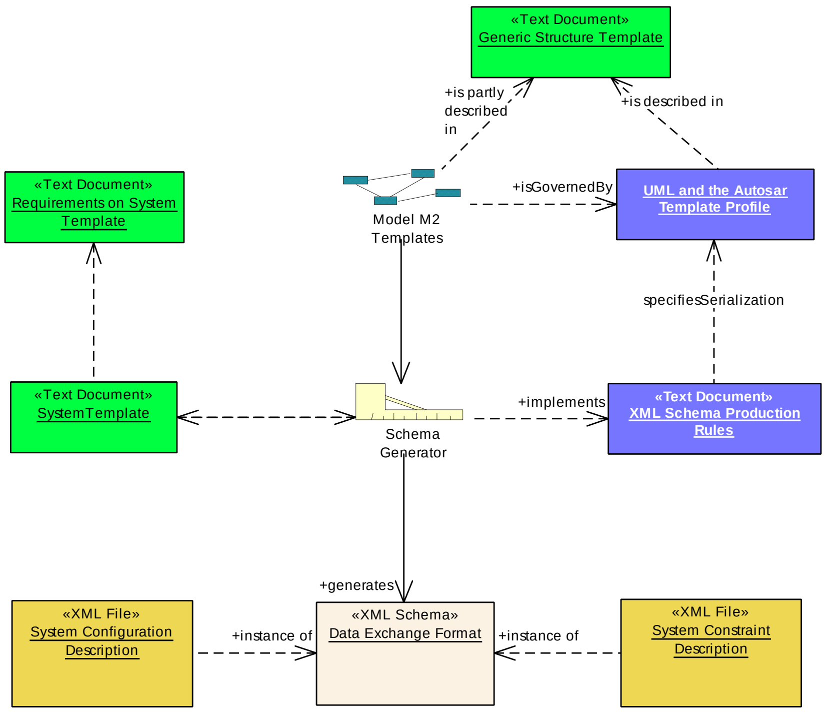

Figure 1.1: Methodology to define templates in AUTOSAR

The following documents describe the various aspects of the methodology:

1. The document called System Template (this document) describes the information that can be captured in the "system constraint" and "system configuration" description, independently from the mapping of this model on XML-technology. This document is based upon the AUTOSAR meta-model and contains an elaborate description of the semantics (the precise meaning) of all the information that can be captured within the relevant parts of this meta-model.

2. The UML and the AUTOSAR Template Profile [1] describes the basic concepts that should be used when creating content of the meta-model.

3. The document called "XML Schema Production Rules" [2] describes how XML is used and how the meta-model designed in the "System Template" should be translated by the "Schema Generator" (MMT) into XML-Schema (XSD) " Data Exchange Format". This "formalization strategy" is to be used for all data that is formally described in the meta-model. In particular this document is

worth to read in order to understand the mapping of the meta-model and the XML based System template.

4. The "Generic Structure Template" [1] describes the top level structure which is common to all AUTOSAR templates and provides AUTOSAR standard mechanisms of modeling elements and patterns.

5. The concrete "Template", the "Data Exchange Format" is an XML schema which is generated out of the meta-model described in the "System Template" using the approach and the patterns defined in the "XML Schema Production Rules". This schema is typically used as input to tools. The M1-level system descriptions are XML files which can be validated against the schema. In that sense they are instances of the schema defining the XML representation of the template.

1.2 Scope

This document describes the system template and its use for the System Constraint Description and the System Configuration Description. In general a filled system template defines the relationship between the pure Software View on the System (represented by a top level SW Component Composition) and a Physical System Architecture with networked ECU instances. The system template is used in two stages of the "AUTOSAR Methodology" [3] (see Figure 1.2).

- As System Constraint Description it serves as input to the AUTOSAR system generator
- As System Configuration Description it defines the output of the AUTOSAR System Configuration Generator and serves as input to the AUTOSAR ECU Configuration Generator for the different ECUs defined in the description.
- As ECU Extract of the System Configuration Description it describes the ECU specific view on the System Description. It is individually generated for each of the System's ECU as the output of the AUTOSAR ECU Configuration Generator.

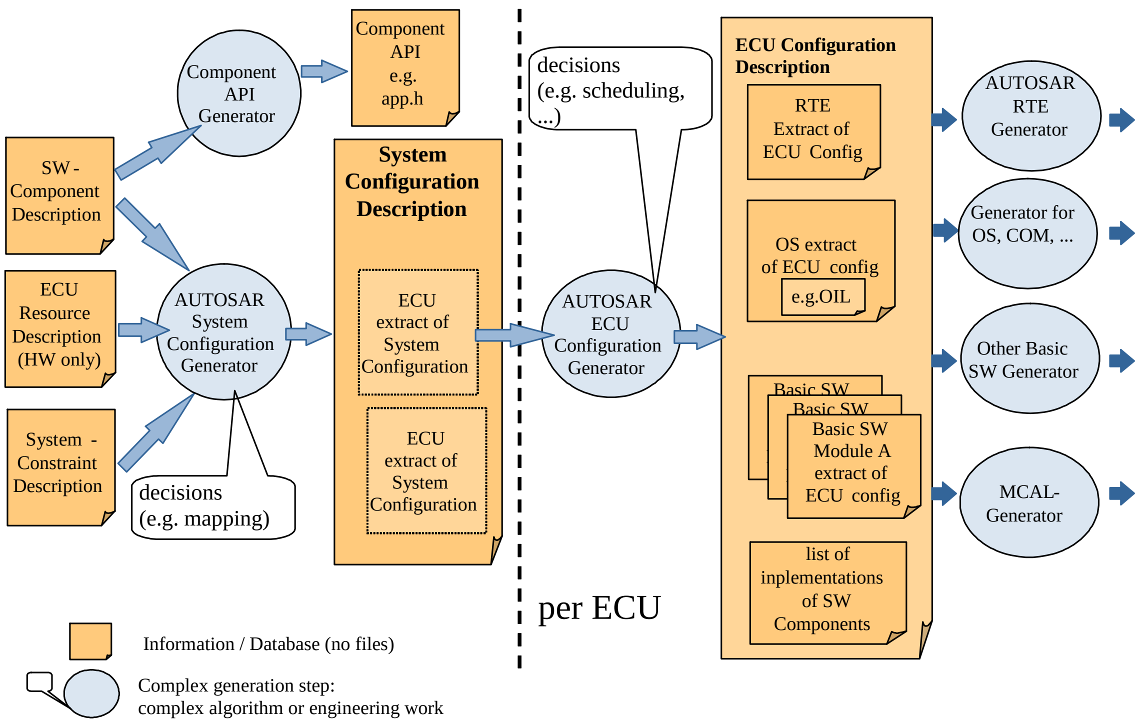

Figure 1.2: AUTOSAR Methodology

The System Template defines five major elements: Topology, Software, Communication, Mapping and Mapping Constraints, which will be defined in detail in the following chapters. Figure 1.3 gives an overview how these are used in the two different descriptions.

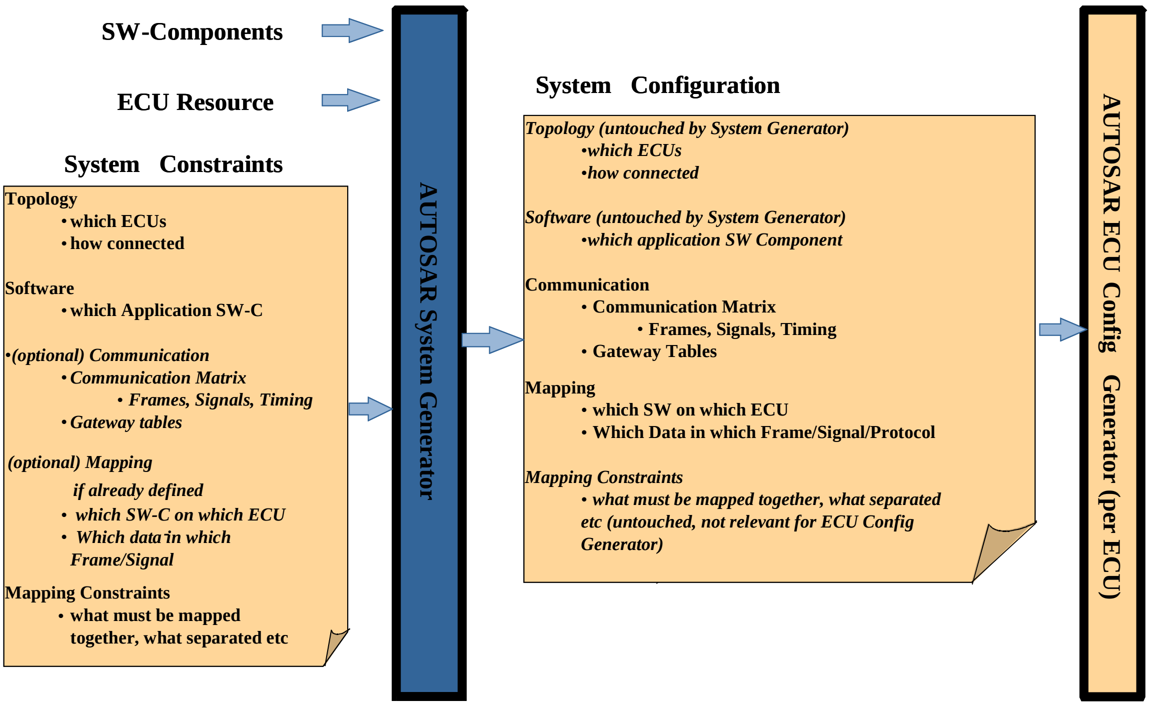

Figure 1.3: Scope of System Constraint Description and System Configuration Description

On Figure 1.3 some of the elements are marked `optional` for the System Constraint Description. If one starts with a new AUTOSAR project, these elements may not be present in the System Constraint Description. No (at least partial) functionality has been mapped yet, thus the communication matrix is not populated. But in most cases, many functional mappings are already predefined and contribute to the population of the communication matrix with their associated signals, thus being present in the System Constraint Description.

Reasons for such a predefinition are manifold. In some cases, hardware setup dictates where certain functionality resides, in some cases, a partial or complete communication matrix and/or completely configured ECUs (HW and SW) of another system (vehicle) has to be taken over. This approach is eased by the fact that System Configuration and System Constraint Description use the same format. That way it is possible to reuse parts of a System Configuration Description of the other system/vehicle in the actual System Constraint Description.

Furthermore, in the figure some of the elements are marked `untouched` for the System Configuration Description. This can have two reasons:

- The System Generator does not modify neither the Topology (networked ECUs) nor the Software, so these parts are just moved from System Constraint Description to System Configuration Description during the generation step.
- In a completed System Configuration Description, all SW components and all ECU-to-ECU communication have been mapped. Thus mapping constraints that limit the flexibility in the mapping phase of the system generator are obsolete

and will not be used in subsequent generator steps. They may however still be present for documentation and validation reasons.

Even if the communication matrix is determined as the result of the system configuration, the ECUs still have to be configured. This is done by the ECU configuration generator, which takes the System Configuration description as input and generates the ECU configuration description. The following guiding principles have been used to determine which information shall be part of the System Configuration Description and which goes into the ECU Configuration Description:

- Information that is common for several ECUs and has to be agreed, shall be part of the System Configuration Description and is thus covered by the System Template.
- Information, that only has ECU-local relevance is part of the ECU Configuration Description.

Thus the ECU Configuration Description will include the OS-schedule, the RTE-configuration and last but not least the configuration of the ECU basic software including the concrete communication drivers on that ECU.

1.3 UML Meta-Model

This chapter gives an overview of the AUTOSAR Unified Modeling Language (UML) meta-model. All AUTOSAR templates use a common meta-model. The templates describe software components, ECU resources, the Basic Software Modules, the ECU Configuration Parameters (ECU Configuration Description and ECU Configuration Parameter Definition) and the System.

The System Template defines all elements, their parameters and their relations, which are necessary for the System Constraint Description and the System Configuration Description.

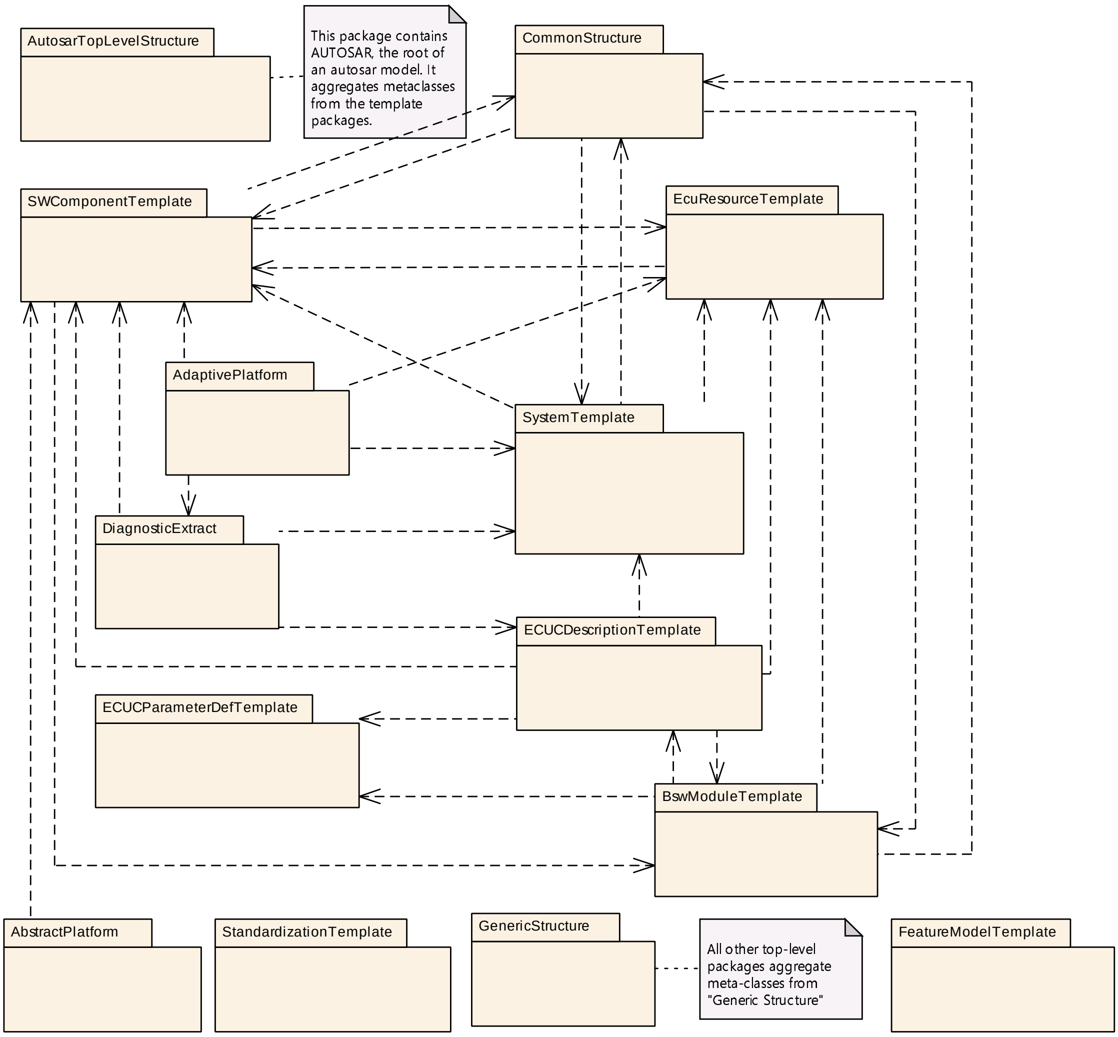

Figure 1.4: AUTOSAR Package Overview

Figure 1.4 shows the overall structure of the meta-model.

The dashed arrows in the diagram describe dependencies in terms of import-relationships between the packages within the meta-model. For example, the package `SystemTemplate` imports meta-classes defined in the packages `GenericStructure` [1], `SWComponentTemplate` [4] and `ECUResourceTemplate` [5].

For clarification, please note that the package `GenericStructure` contains some fundamental infrastructure meta-classes and common patterns that are described in [1]. As these are used by all other template specification the dependency associations are not depicted in the diagram for the sake of clarity.

Generic Structure provides details about

- AUTOSAR Top level structure,
- Commonly used meta-classes and primitives
- Variant Handling

- Documentation

The ECU Resource Template deals with the description of the hardware resources of an ECU. The collection of all ECUs, which are integrated in the car, are described in the topology part of the System Configuration Description/System Constraint Description. Each of these ECUInstances uses the ECU Resource Template to describe the hardware resources. That's the reason, why the topology part has references to the ECU Resource Description.

The SW component description describes the SW components as well as their communication by data elements. The top-level software composition (RootSwCompositionPrototype) is part of the System Template (Software). This top-level software composition contains the functionality of the full system and describes the complete application software architecture of this system. The definition of the top level software composition uses the elements defined in the SW Component Template, like e.g. SwComponentType, PortInterface, AssemblySwConnector and DelegationSwConnector. That's why the System Description has references to the Software Component Description. The top level software composition is described in more detail in chapter 4.

Every template starts with an element AUTOSAR. While the models created in accordance to this guide are independent of the used formalization, it may still help the reader's understanding to note that AUTOSAR would also typically be the root element of a XML Schema generated from such a model. AUTOSAR can then contain one or more nested packages, simply allowing to further structure the contents of the M1 model.

1.4 Document Conventions

Technical terms are typeset in mono spaced font, e.g. PortPrototype. As a general rule, plural forms of technical terms are created by adding "s" to the singular form, e.g. PortPrototypes. By this means the document resembles terminology used in the AUTOSAR XML Schema.

This document contains constraints in textual form that are distinguished from the rest of the text by a unique numerical constraint ID, a headline, and the actual constraint text starting after the ⌈ character and terminated by the ⌋ character.

The purpose of these constraints is to literally constrain the interpretation of the AUTOSAR meta-model such that it is possible to detect violations of the standardized behavior implemented in an instance of the meta-model (i.e. on M1 level).

Makers of AUTOSAR tools are encouraged to add the numerical ID of a constraint that corresponds to an M1 modeling issue as part of the diagnostic message issued by the tool.

The attributes of the classes introduced in this document are listed in form of class tables. They have the form shown in the example of the top-level element AUTOSAR:

Please note that constraints are not supposed to be enforceable at any given time in an AUTOSAR workflow. During the development of a model, constraints may legitimately be violated because an incomplete model will obviously show inconsistencies.

However, at specific points in the workflow, constraints shall be enforced as a safeguard against misconfiguration.

The points in the workflow where constraints shall be enforced, sometimes also known as the "binding time" of the constraint, are different for each model category, e.g. on the classic platform, the constraints defined for software-components are typically enforced prior to the generation of the RTE while the constraints against the definition of an Ecu extract shall be applied when the Ecu configuration for the Com stack is created.

For each document, possible binding times of constraints are defined and the binding times are typically mentioned in the constraint themselves to give a proper orientation for implementers of AUTOSAR authoring tools.

Let AUTOSAR be an example of a typical class table. The first rows in the table have the following meaning:

Class: The name of the class as defined in the UML model.

Package: The UML package the class is defined in. This is only listed to help locating the class in the overall meta model.

Note: The comment the modeler gave for the class (class note). Stereotypes and UML tags of the class are also denoted here.

Base Classes: If applicable, the list of direct base classes.

The headers in the table have the following meaning:

Attribute: The name of an attribute of the class. Note that AUTOSAR does not distinguish between class attributes and owned association ends.

Type: The type of an attribute of the class.

Mul.: The assigned multiplicity of the attribute, i.e. how many instances of the given data type are associated with the attribute.

Kind: Specifies, whether the attribute is aggregated in the class (`aggr` aggregation), an UML attribute in the class (`attr` primitive attribute), or just referenced by it (`ref` reference). Instance references are also indicated (`iref` instance reference) in this field.

Note: The comment the modeler gave for the class attribute (role note). Stereotypes and UML tags of the class are also denoted here.

Please note that the chapters that start with a letter instead of a numerical value represent the appendix of the document. The purpose of the appendix is to support the explanation of certain aspects of the document and does not represent binding conventions of the standard.

The verbal forms for the expression of obligation specified in [TPS_STDT_00053] shall be used to indicate requirements, see Standardization Template, chapter Support for Traceability ([6]).

The representation of requirements in AUTOSAR documents follows the table specified in [TPS_STDT_00078], see Standardization Template, chapter Support for Traceability ([6]).

1.4.1 Detailed Representation of InstanceRef Associations

As a special type of association "instanceRef" refers to an exact instance of the referenced class, requiring additional information of the target and the context. This is explained in detail in the AUTOSAR Generic Structure Template [1]. Each "instanceRef" association can both be represented by the short form and by an detailed representation. For readability the diagrams in the main body of the specification use the short form. The detailed descriptions can be found in the Appendix B.

1.4.2 Variant Handling

The System Template supports the creation of Variants in many of its model elements. In the Metamodel all locations that may exhibit variability are marked with the stereotype `atpVariation`. This allows the definition of possible variation points. Tagged Values are used to specify additional informations.

There are four types of locations in the metamodel which may exhibit variability:

- Aggregations
- Associations
- Attribute Values
- Classes providing property sets

The reasons for the attachment of the stereotype `atpVariation` to certain model elements and the consequences for other model elements are explained in class tables in the following chapters. More details about the AUTOSAR Variant Handling Concept can be found in the AUTOSAR Generic Structure Template [1].

1.4.3 Timing Extensions

With AUTOSAR Release 4.0 a new set of concepts for the description and analysis of end-to-end timing constraints is introduced by the Specification of Timing Extensions. A subset of these extensions aims for the system level and can be used to enhance the descriptions that are already available in the System Template.

A dedicated description of the timing extensions that can be used at system level is given in chapter 3 (System timing) in the Specification of Timing Extensions [7].

1.4.4 Documentation Support

With AUTOSAR Release 4.0 the AUTOSAR XML schema provides support for integrated and well structured documentation. More details about the AUTOSAR Documentation Support concept can be found in the AUTOSAR Generic Structure Template [1]. An optional documentation block can be applied to any identifiable element. Furthermore, as shown in figure 1.5, the System Template provides the possibility of adding additional documentation to several non-identifiable elements. The documentation of a `System` is composed of several chapters.

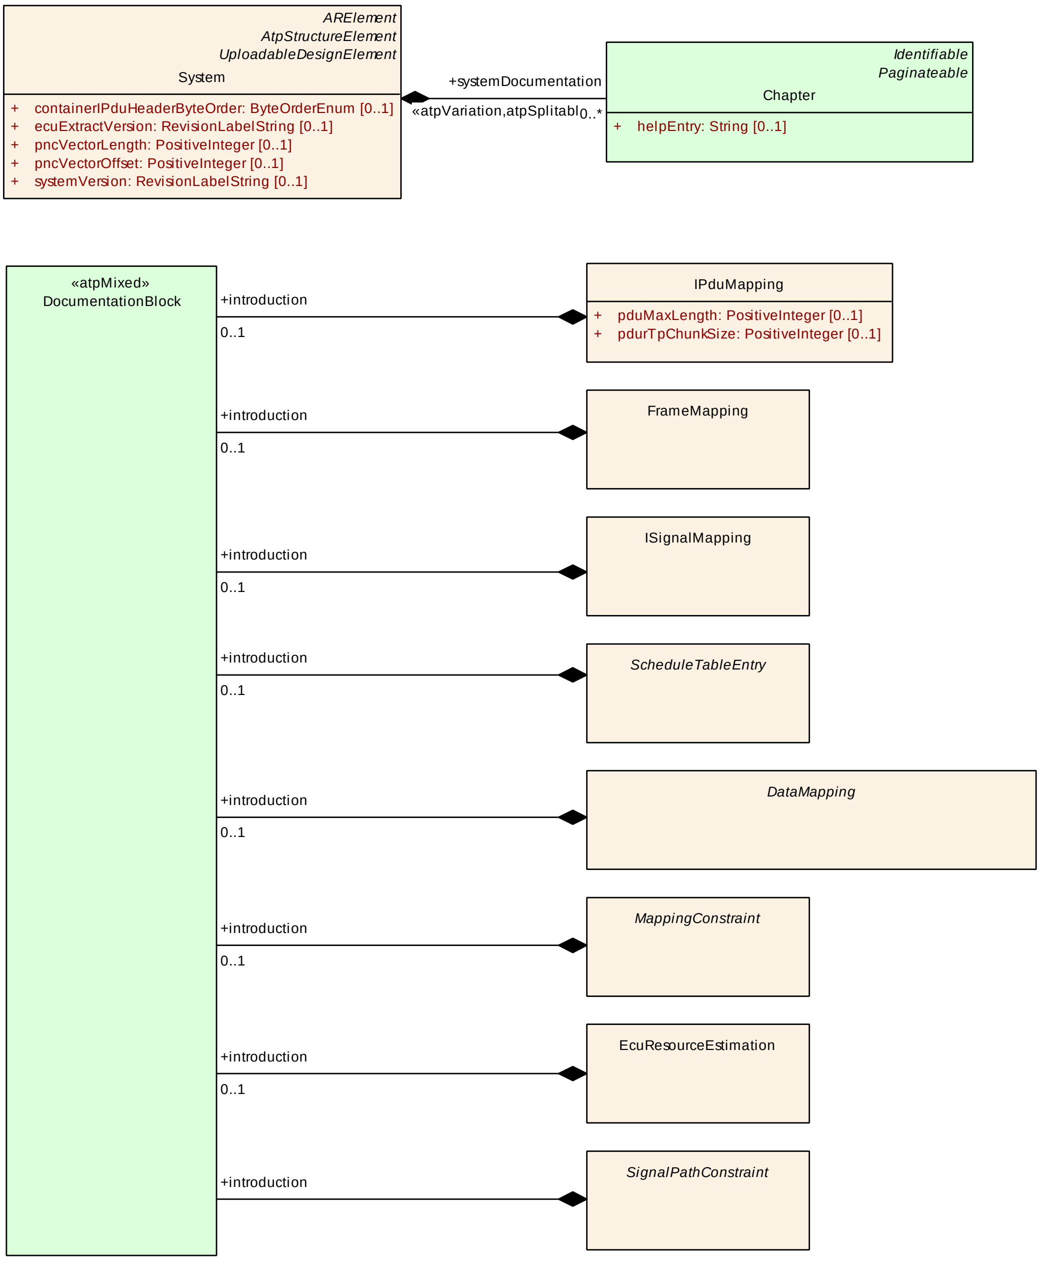

Figure 1.5: System Template Documentation Support

1.4.5 Stereotype atpSplitable in the System Template

The stereotype ≪atpSplitable≫ is used in the System Template to support step-wise processes, where the System Configuration Description is completed incrementally over a development process. Example:

1) Description of Communication only consists of interaction signals (ISignal). This is enough information to create an individual ECU's RTE, and even contains enough information to configure an ECU where the actual Frame/Pdu communication is being handled post-build.

2) In a second step, the communication matrix is being completed for a concrete vehicle. Pdus and Frames, along with their Triggerings are being added to the previous System Description. This model then contains the full information about an ECU's communication, especially containing the additional information to generate the post build information.

So, in this 2-step approach, an OEM could deliver the incomplete ECU extract from step (1) to the ECU integrator, who can then build a complete software image for the ECU. In the 2nd step, the ECU extract will be completed by the previously missing information, but as the first extract will still be valid due to the ≪atpSplitable≫ construct, the ECU including the flashed image from step (1) can be (re)used as it is, and just will be completed with the post build information, e.g. Frames and Pdus.

Further details about the ≪atpSplitable≫ stereotype can be found in the Generic Structure Template [1].

1.5 AUTOSAR System Template and ASAM FIBEX

FIBEX (Field Bus Exchange Format) [8] is an XML exchange format proposed for data exchange between tools that deal with bus communication Systems. The format supports the most common automotive data buses: LIN [9], CAN [10], MOST [11], FlexRay [12]. The covered areas of the exchange format are the functional network, system topology and the communication level. The functional network describes the software architecture of the system. In the system topology the logical layout of the system is described. This means it is documented which ECU is connected to which bus. The central purpose of a communication system is the exchange of frames with certain properties. The format is able to describe frames and their timing properties.

In future versions of the System Template a common subset between ASAM FIBEX and AUTOSAR will be harmonized. The current version of the System Template contains already the ASAM FIBEX description for communication and topology. Due to requirements of AUTOSAR some extensions were made to those descriptions. For instance the communication part is extended by a concept for PDUs (I-Pdus and N-Pdus). The harmonization between ASAM FIBEX and AUTOSAR System Template is not finalized at this time.

In the UML Meta-Model the FIBEX contents are located in an own FIBEX UML Package. The top level `FibexElement` is referenced by the top level element `System` of the System Template. Similar to the usage of the `ARElement`, specializations of the `FibexElement` represent elementary building blocks within the FIBEX package. Each of this elements will be described in more detail in the following chapters.

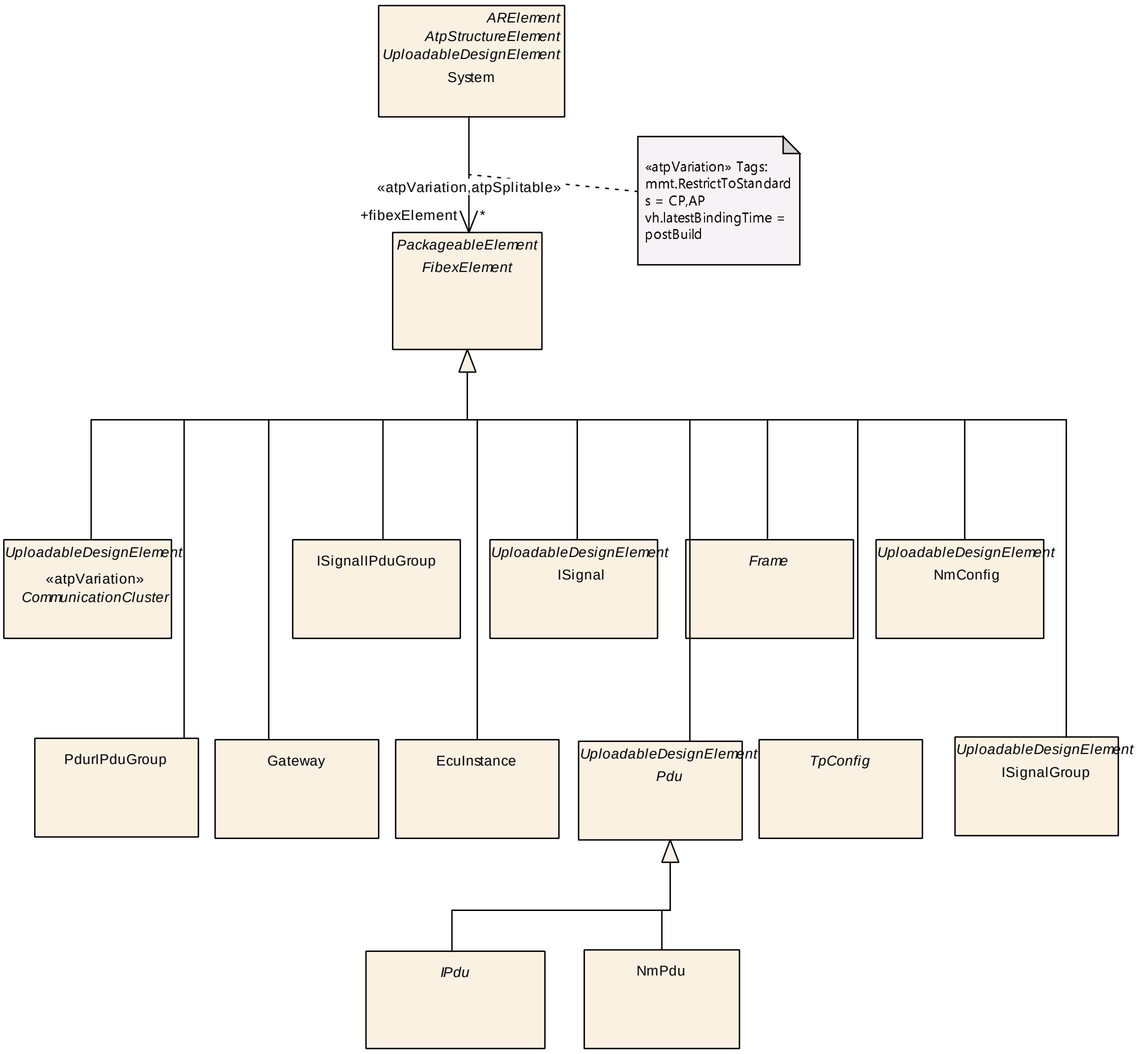

Figure 1.6: Fibex Elements

2 System

The top level element of the System Template is the class `System`, as shown in figure 2.1.

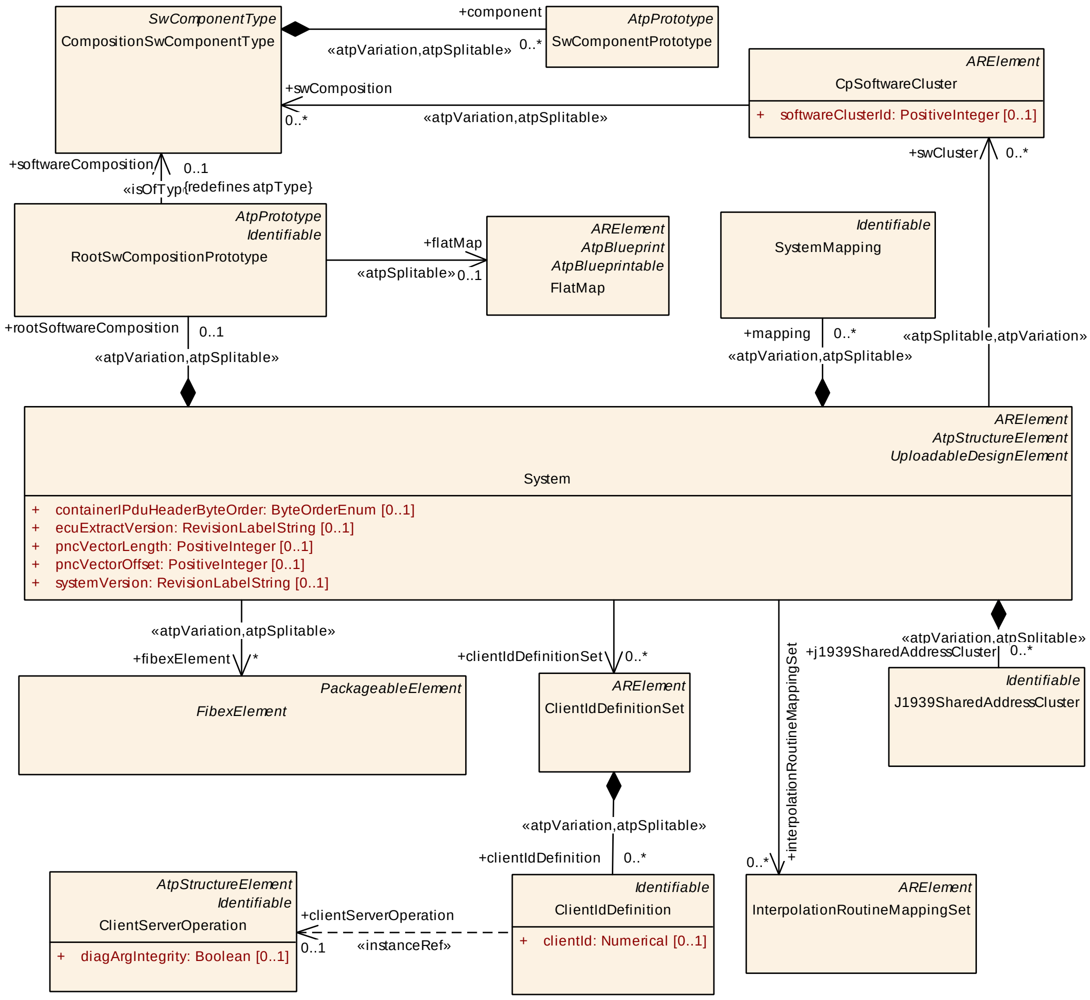

Figure 2.1: System Template Overview

Class	**System**			
Package	M2::AUTOSARTemplates::SystemTemplate			
Note	The top level element of the System Description. The System description defines five major elements: Topology, Software, Communication, Mapping and Mapping Constraints. The System element directly aggregates the elements describing the Software, Mapping and Mapping Constraints; it contains a reference to an ASAM FIBEX description specifying Communication and Topology. **Tags:** atp.recommendedPackage=Systems

interpolation Routine MappingSet	InterpolationRoutine MappingSet	*	ref	This reference identifies the InterpolationRoutineMapping Sets that are relevant in the context of the enclosing System.
j1939Shared AddressCluster	J1939SharedAddress Cluster	*	aggr	Collection of J1939Clusters that share a common address space for the routing of messages. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=j1939SharedAddressCluster.shortName, j1939SharedAddressCluster.variationPoint.shortLabel vh.latestBindingTime=postBuild
mapping	SystemMapping	*	aggr	Aggregation of all mapping aspects (mapping of SW components to ECUs, mapping of data elements to signals, and mapping constraints). In order to support OEM / Tier 1 interaction and shared development for one common System this aggregation is atpSplitable and atpVariation. The content of System Mapping can be provided by several parties using different names for the SystemMapping. This element is not required when the System description is used for a network-only use-case. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=mapping.shortName, mapping.variation Point.shortLabel vh.latestBindingTime=postBuild
pncVector Length	PositiveInteger	0..1	attr	Length of the partial networking request release information vector (in bytes).
pncVectorOffset	PositiveInteger	0..1	attr	Absolute offset (with respect to the NM-PDU) of the partial networking request release information vector that is defined in bytes as an index starting with 0.

▽

△

Class	System			
rootSoftware Composition	RootSwComposition Prototype	0..1	aggr	Aggregation of the root software composition, containing all software components in the System in a hierarchical structure. This element is not required when the System description is used for a network-only use-case. atpVariation: The RootSwCompositionPrototype can vary. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=rootSoftwareComposition.shortName, root SoftwareComposition.variationPoint.shortLabel vh.latestBindingTime=systemDesignTime
swCluster	CpSoftwareCluster	*	ref	CP Software Clusters of this System **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=swCluster.cpSoftwareCluster, sw Cluster.variationPoint.shortLabel vh.latestBindingTime=systemDesignTime
system Documentation	Chapter	*	aggr	Possibility to provide additional documentation while defining the System. The System documentation can be composed of several chapters. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=systemDocumentation.shortName, system Documentation.variationPoint.shortLabel vh.latestBindingTime=systemDesignTime xml.sequenceOffset=-10
systemVersion	RevisionLabelString	0..1	attr	Version number of the System Description.

Table 2.1: System

System has relationships to all elements that define a system constraint description or system configuration description. It aggregates the SystemMapping and RootSwCompositionPrototype elements. SystemMapping deals with mapping of software components to ECUs as well as with the mapping of data elements that are to be exchanged between software components onto signals and frames. The RootSwCompositionPrototype element contains a reference to the top level software composition.

[TPS_SYST_02364] Scope of the System ⌈The System defines a vehicle representation and describes the software related parts of the vehicle. This includes the Software Components that are deployed to ECUs of the vehicle but also the means for the Software to communicate with each other, such as network topology and communication matrix.⌋

[constr_3028] FibexElements

Imposition time: IT_SysDesc

⌈Each FibexElement that is used in the System Description shall be referenced by the System element in the role FibexElement.⌋

FibexElements can be defined in a stand alone and reusable way (hence they can simply be created in any package like ARElements), but on the other hand it shall be clear that a certain FibexElement actually belongs to a certain System Description. Thus, all FibexElements used within a System Description (i.e. contributing to the specification of the System communication and topology) shall be referenced from the System element. More details about the integration of FIBEX into the System Template will be given in chapter 1.5.

[TPS_SYST_01002] System Category

Upstream requirements: RS_SYST_00003, RS_SYST_00027

⌈The System shall have a category element defined which indicates the role of this work product.⌋

[TPS_SYST_01003] Standardized System Category Definitions

Upstream requirements: RS_SYST_00003, RS_SYST_00027

⌈

category	*Meaning*
SYSTEM_CONSTRAINTS	The System class is used to describe System Constraints. In this usage, it forms the core element of a System Constraints Description, serving as an input to the AUTOSAR System Generator.
SYSTEM_DESCRIPTION	The System class is used to describe the System Configuration of a complete AUTOSAR System. In this usage, it forms the core element of a System Description, the output of the AUTOSAR System Generator.
SYSTEM_EXTRACT	The System class is used to describe a subsystem specific view on the complete System Description. The System Extract is not fully decomposed and still contains compositions. The SYSTEM_EXTRACT is the basis for designing subsystems.
ECU_EXTRACT	The System class is used to describe the ECU specific view on the complete System Description. In this usage, it forms the core element of ECU Extract, the output of the AUTOSAR ECU Configuration Extractor. The ECU Extract is fully decomposed and contains only atomic software components. The ECU Extract is the basis for setting up the ECU Configuration.
ABSTRACT_SYSTEM_DESCRIPTION	The System is used to describe a functional (solution-independent/abstract) system design. It can be taken as basis for the development of the SYSTEM_DESCRIPTION. No structural constraints are applied on the transformation of the ABSTRACT_SYSTEM_DESCRIPTION to the SYSTEM_DESCRIPTION.
ECU_SYSTEM_DESCRIPTION	The System is used to describe the closed view on one ECU (note that an AUTOSAR ECU is defined being one microprocessor running one AUTOSAR Stack). It can be derived from a SYSTEM_EXTRACT or it can be designed independently and mapped to a SYSTEM_EXTRACT. The ECU_SYSTEM_DESCRIPTION is not fully decomposed and still may contain compositions.
SW_CLUSTER_SYSTEM_DESCRIPTION	System that describes the content of a single CpSoftwareCluster.
RPT_SYSTEM	System which describes the rapid prototyping algorithm in the format of AUTOSAR Software Components. For more details see the Software Component Template [4] and TR_Methodology [3].

⌋

Note: SYSTEM_EXTRACT does not prescribe the number of micro controllers / cores for one ECU from the OEM perspective.

- Supplier decides to design one AUTOSAR ECU with multicore support leads to one ECU_EXTRACT supporting one AUTOSAR stack
- Supplier decides to design two AUTOSAR ECUs (i.e., two micro-controllers) in one box leads to two ECU_EXTRACTs supporting two AUTOSAR stacks

[constr_3027] Existence of `ecuExtractVersion`

Imposition time: IT_EcuExt

⌈In case the category of the System is SYSTEM_EXTRACT or ECU_EXTRACT the ecuExtractVersion attribute shall be defined.⌋

2.1 Data interpretation of bus content in different contexts

A System Description can be used for different purposes:

- as input for the creation of the Base Ecu Configuration
- as input for bus monitoring and network analysis tools

In some cases the System Description is interpreted in a different way between Ecuc tools and network analysis tools. This chapter collects such use cases and describes the differences in the interpretation of the configuration data.

2.1.1 Nm NID/CBV

[TPS_SYST_02366] NID/CBV signals shall be ignored by Ecuc tools ⌈If NID/CBV are enabled (nmCbvPosition and nmNidPosition are configured), the Signals that are defined at the position of the respective NID/CBV bytes shall be ignored by Base Ecuc generators since these signals are not processed by COM.⌋

Please note that there may be the use case to define the Signals that represent the NID and CBV in the NmPdu for bus monitoring or network analysis purposes.

2.2 ClientIdDefinitionSet

In the ClientIdDefinitionSet all Client Identifiers of the transaction handle used for a inter-ECU client server communication can be defined that belong to the System that refers the ClientIdDefinitionSet.

Class	ClientIdDefinitionSet			
Package	M2::AUTOSARTemplates::SystemTemplate			
Note	Set of Client Identifiers that are used for inter-ECU client-server communication in the System. **Tags:** atp.recommendedPackage=ClientIdDefinitionSets			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
clientId Definition	ClientIdDefinition	*	aggr	Definition of a Client Identifier that will be used by the RTE in a inter-ECU client-server communication. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=clientIdDefinition.shortName, clientId Definition.variationPoint.shortLabel vh.latestBindingTime=postBuild

Table 2.2: ClientIdDefinitionSet

Class	ClientIdDefinition			
Package	M2::AUTOSARTemplates::SystemTemplate			
Note	Several clients in one client-ECU can communicate via inter-ECU client-server communication with a server on a different ECU, if a client identifier is used to distinguish the different clients. The Client Identifier of the transaction handle that is used by the RTE can be defined by this element.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	ClientIdDefinitionSet.clientIdDefinition			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
clientId	Numerical	0..1	attr	The Client Identifier of the transaction handle used for an inter-ECU client server communication is defined by this attribute. If defined the RTE generator shall use this client Id.
clientServer Operation	ClientServerOperation	0..1	iref	Reference to the ClientServerOperation that is called by the client. **InstanceRef implemented by:** OperationInSystem InstanceRef

Table 2.3: ClientIdDefinition

[constr_3117] Allowed value of attribute `clientId`

Imposition time: `IT_SysDesc`

⌈Within the context of one `ClientIdDefinition`, the value of attribute `clientId` shall be in the range of `ClientIdRange.lowerLimit` and `ClientIdRange.upperLimit` for the `ClientIdRange` that is aggregated by the `EcuInstance` onto which the `SwComponentPrototype`s included in the `ClientIdDefinition.clientServerOperation` are mapped.⌋

Please note that the `clientId` is bound to the ClientServer relationship and does not represent a globally unique identifier of the Client call. ClientIds can be reused in the context of a different ClientServer relationship.

[constr_3118] Valid reference target for ClientIdDefinition.clientServerOperation.contextPort

Imposition time: IT_SysDesc

⌈In the context of the definition of a ClientIdDefinition, the reference clientServerOperation.contextPort shall only refer to an RPortPrototype.⌋

Rationale: the definition of a client ID does only make sense in the context of a client of a ClientServerOperation.

[constr_5393] Existence of clientId

Imposition time: IT_SysDesc

⌈For each ClientIdDefinition, the attribute clientId shall exist.⌋

[constr_5394] Existence of clientServerOperation

Imposition time: IT_SysDesc

⌈For each ClientIdDefinition, the attribute clientServerOperation shall exist.⌋

2.3 InterpolationRoutingMappingSet

The System defines with the interpolationRoutineMappingSet reference all InterpolationRoutineMappingSets that are relevant in the context of the System. More details about the InterpolationRoutineMappingSets, InterpolationRoutineMappings and InterpolationRoutines can be found in the Software Component Template [4].

Class	**InterpolationRoutineMappingSet**			
Package	M2::AUTOSARTemplates::SWComponentTemplate::MeasurementAndCalibration::InterpolationRoutineMappingSet			
Note	This meta-class specifies a set of interpolation routine mappings. **Tags:** atp.recommendedPackage=InterpolationRoutineMappingSets			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
interpolationRoutineMapping	InterpolationRoutineMapping	*	aggr	This specifies one particular mapping of recordlayout and its matching interpolationRoutines.

Table 2.4: InterpolationRoutineMappingSet

Class	InterpolationRoutineMapping			
Package	M2::AUTOSARTemplates::SWComponentTemplate::MeasurementAndCalibration::InterpolationRoutineMappingSet			
Note	This meta-class provides a mapping between one record layout and its matching interpolation routines. This allows to formally specify the semantics of the interpolation routines. The use case is such that the curves/Maps define an interpolation method. This mapping table specifies which interpolation routine implements methods for a particular record layout. Using this information, the implementer of a software-component can select the appropriate interpolation routine.			
Base	*ARObject*			
Aggregated by	InterpolationRoutineMappingSet.interpolationRoutineMapping			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
interpolationRoutine	InterpolationRoutine	*	aggr	This is one particular interpolation routine which is mapped to the record layout.
swRecordLayout	SwRecordLayout	0..1	ref	This refers to the record layout which is mapped to interpolation routines.

Table 2.5: InterpolationRoutineMapping

Class	InterpolationRoutine			
Package	M2::AUTOSARTemplates::SWComponentTemplate::MeasurementAndCalibration::InterpolationRoutineMappingSet			
Note	This represents an interpolation routine taken to evaluate the contents of a curve or map against a specific input value.			
Base	*ARObject*			
Aggregated by	InterpolationRoutineMapping.interpolationRoutine			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
interpolationRoutine	BswModuleEntry	0..1	ref	This specifies a BswModuleEntry which implements the current interpolation method for the given record layout. **Tags:** xml.sequenceOffset=30
isDefault	Boolean	0..1	attr	This attribute specifies whether the enclosing InterpolationRoutine is considered the default in the context (defined by the System Template) of a given collection InterpolationRoutineMapping that owns the enclosing InterpolationRoutine. **Tags:** xml.sequenceOffset=20
shortLabel	Identifier	0..1	attr	This is the name of the interpolation method which is implemented by the referenced bswModuleEntry. It corresponds to swInterpolationMethod in SwDataDefProps. **Tags:** xml.sequenceOffset=10

Table 2.6: InterpolationRoutine

[constr_5114] Semantics of `InterpolationRoutine.isDefault`

Imposition time: `IT_SysDesc`

⌈For each `SwRecordLayout` that is referenced by one or more `InterpolationRoutineMapping`s that are aggregated by `InterpolationRoutineMappingSet`s that are referenced from a `System` in the role `interpolationRoutineMappingSet`, only one of the collection of aggregated `InterpolationRoutine`s shall have attribute `isDefault` set to True.⌋

3 Topology

This chapter explains how a vehicle's physical System Topology is being modeled in AUTOSAR (Example: Figure 3.1). A topology is formed by a number of EcuInstances that are interconnected to each other in order to form ensembles of ECUs and CommunicationClusters, which are further detailed by providing information on bus-specific properties.

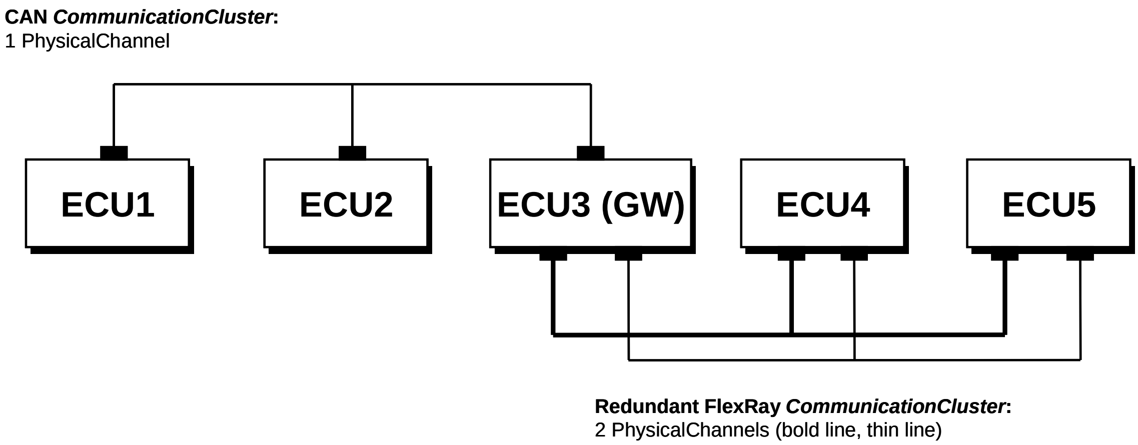

Figure 3.1: Example for a Communication Cluster within a physical network topology

In the AUTOSAR methodology [3] the topology description is one of the inputs for the System Generator. It serves as constraints for mapping the Software Components (see chapter 5.1) contained in the RootSwCompositionPrototype as well as for defining the System Communication matrix (see chapter 6). Gateways which allow the exchange of Signals between CommunicationClusters are covered in chapter 8.

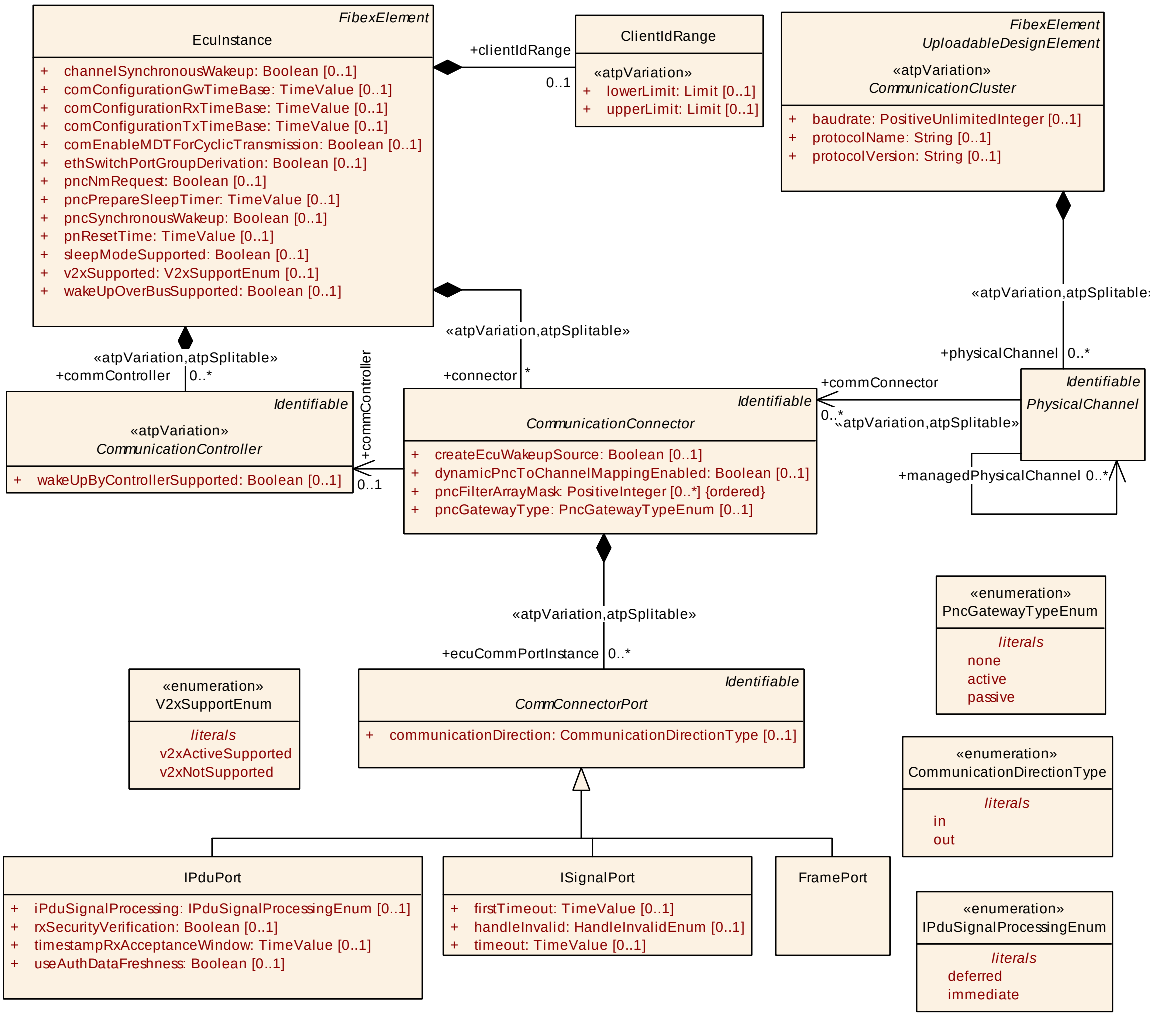

Figure 3.2: Topology elements (Topology)

3.1 ECUs and their communication capabilities

Within a System Topology, the ECUs actually being connected with each other are described in the form of `EcuInstance`s. An `EcuInstance` needs to have one or more `CommunicationController`, the actual hardware device by means of which devices send and receive frames from the communication medium. Furthermore, the `EcuInstance` has one or more `CommunicationConnector`s which describe the bus interfaces of the ECUs and to specify the sending/receiving behavior.

3.1.1 ECU Instance

[TPS_SYST_01005] Definition of EcuInstance

Upstream requirements: RS_SYST_00013

⌈The EcuInstance defines one instance of the AUTOSAR stack.⌋

The actual description of the ECU hardware resources is done by the means of the ECU Resource Template [5]: It uses the HwElement class and its aggregated hardware elements for defining a specific ECU type. In other words the Ecu Resource Template "Ecu" is used to describe the physical box (HwElement of category Ecu) containing the electronics which may contain several microcontrollers with several AUTOSAR Stack instances running.

[TPS_SYST_01006] Assign ECU type to EcuInstance

Upstream requirements: RS_SYST_00013

⌈The process of assigning an ECU type to EcuInstance is a mapping step (see [TPS_SYST_01019]) and performed latest in the System Generation step.⌋

An EcuInstance can serve as a gateway if it is connected to two or more different clusters by two or more of its CommunicationControllers.

Class	**EcuInstance**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology			
Note	ECUInstances are used to define the ECUs used in the topology. The type of the ECU is defined by a reference to an ECU specified with the ECU resource description. **Tags:** atp.recommendedPackage=EcuInstances			
Base	*ARObject*, *CollectableElement*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
associatedCom IPduGroup	ISignalIPduGroup	*	ref	With this reference it is possible to identify which ISignal IPduGroups are applicable for which Communication Connector/ ECU. Only top level ISignalIPduGroups shall be referenced by an EcuInstance. If an ISignalIPduGroup contains other ISignalIPduGroups than these contained ISignalIPdu Groups shall not be referenced by the EcuInstance. Contained ISignalIPduGroups are associated to an Ecu Instance via the top level ISignalIPduGroup.

▽

△

Class	**EcuInstance**			
associated Consumed Provided ServiceInstance Group	ConsumedProvided ServiceInstanceGroup	*	ref	With this reference it is possible to identify which ConsumedProvidedServiceInstanceGroups are applicable for which ECUInstance. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=associatedConsumedProvidedService InstanceGroup.consumedProvidedServiceInstanceGroup, associatedConsumedProvidedServiceInstance Group.variationPoint.shortLabel vh.latestBindingTime=postBuild
associatedPdur IPduGroup	PdurIPduGroup	*	ref	With this reference it is possible to identify which PduR IPdu Groups are applicable for which Communication Connector/ ECU.
channel Synchronous Wakeup	Boolean	0..1	attr	If this parameter is available and set to true, then all available channels will be woken up as soon as at least one channel wakeup occurs. If PNCs are configured, then all PNCs will be requested upon a channel wakeup.
clientIdRange	ClientIdRange	0..1	aggr	Restriction of the Client Identifier for this Ecu to an allowed range of numerical values. The Client Identifier of the transaction handle is generated by the client RTE for inter-Ecu Client/Server communication.
com Configuration GwTimeBase	TimeValue	0..1	attr	The period between successive calls to Com_Main FunctionRouteSignals of the AUTOSAR COM module in seconds.
com ConfigurationRx TimeBase	TimeValue	0..1	attr	The period between successive calls to Com_Main FunctionRx of the AUTOSAR COM module in seconds.
com ConfigurationTx TimeBase	TimeValue	0..1	attr	The period between successive calls to Com_Main FunctionTx of the AUTOSAR COM module in seconds.
comEnable MDTForCyclic Transmission	Boolean	0..1	attr	Enables for the Com module of this EcuInstance the minimum delay time monitoring for cyclic and repeated transmissions (TransmissionModeTiming has cyclic Timing assigned or eventControlledTiming with numberOf Repetitions > 0).
commController	Communication Controller	*	aggr	CommunicationControllers of the ECU. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=commController.shortName, comm Controller.variationPoint.shortLabel vh.latestBindingTime=postBuild
connector	Communication Connector	*	aggr	All channels controlled by a single controller. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=connector.shortName, connector.variation Point.shortLabel vh.latestBindingTime=postBuild
dltConfig	DltConfig	0..1	aggr	Describes the Dlt configuration on this EcuInstance.
doIpConfig	DoIpConfig	0..1	aggr	DoIp configuration on this EcuInstance. **Tags:** atp.Status=draft
ecuTaskProxy	OsTaskProxy	*	ref	Reference to OsTaskProxies assigned to the Ecu Instance. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=ecuTaskProxy

▽

△

Class	**EcuInstance**			
ethSwitchPort Group Derivation	Boolean	0..1	attr	Defines whether the derivation of SwitchPortGroups based on VLAN and/or CouplingPort.pncMapping shall be performed for this EcuInstance. If not defined the derivation shall not be done.
firewallRule	StateDependentFirewall	*	ref	Firewall rules defined in the context of an EcuInstance. **Tags:** atp.Status=candidate
partition	EcuPartition	*	aggr	Optional definition of Partitions within an Ecu.
pncNmRequest	Boolean	0..1	attr	Defines if this EcuInstance shall request Nm on all its PhysicalChannels which have Nm variant set to FULL each time a PNC is requested.
pncPrepare SleepTimer	TimeValue	0..1	attr	Time in seconds the PNC state machine shall wait in PNC_PREPARE_SLEEP.
pnc Synchronous Wakeup	Boolean	0..1	attr	If this parameter is available and set to true then all available PNCs will be woken up as soon as a channel wakeup occurs. This is ensured by adding all PNCs to all channel wakeup sources during upstream mapping.
pnResetTime	TimeValue	0..1	attr	Specifies the runtime of the reset timer in seconds. This reset time is valid for the reset of PN requests in the EIRA and in the ERA.
sleepMode Supported	Boolean	0..1	attr	Specifies whether the ECU instance may be put to a "low power mode" • true: sleep mode is supported • false: sleep mode is not supported Note: This flag may only be set to "true" if the feature is supported by both hardware and basic software.
tcpIpIcmpProps	EthTcpIpIcmpProps	0..1	ref	EcuInstance specific ICMP (Internet Control Message Protocol) attributes
tcpIpProps	EthTcpIpProps	0..1	ref	EcuInstance specific TcpIp Stack attributes.
v2xSupported	V2xSupportEnum	0..1	attr	This attribute is used to control the existence of the V2X stack on the given EcuInstance.
wakeUpOver BusSupported	Boolean	0..1	attr	Driver support for wakeup over Bus.

Table 3.1: EcuInstance

[constr_3008] `EcuInstance` subelements

Imposition time: `IT_SysDesc`

⌈The `CommunicationConnector` and the `CommunicationController` that is referenced by the `CommunicationConnector` shall be owned by the same `EcuInstance`.⌋

Class	**ClientIdRange**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology

⌈The ClientIdRange defined for an EcuInstance shall not overlap with the ClientIdRange of any other EcuInstance in the context of the enclosing System.⌋

[constr_5396] Existence of ClientIdRange.lowerLimit

Imposition time: IT_SysDesc

⌈For each ClientIdRange, the attribute lowerLimit shall exist.⌋

[constr_5397] Existence of ClientIdRange.upperLimit

Imposition time: IT_SysDesc

⌈For each ClientIdRange, the attribute upperLimit shall exist.⌋

3.1.2 Communication Controller

[TPS_SYST_01007] Definition of CommunicationController

Upstream requirements: RS_SYST_00013

⌈A CommunicationController is a dedicated hardware device by means of which hosts are sending frames to and receiving frames from the communication medium.⌋

[TPS_SYST_01008] Assign CommunicationController to the AUTOSAR Communication Peripheral

Upstream requirements: RS_SYST_00013

⌈In order to illustrate the relationship of an CommunicationController to the HwElement with category CommunicationController defined in the ECU Resource Description, a mapping between these two classes may be specified using the CommunicationControllerMapping (see [TPS_SYST_01014]).⌋

Class	«atpVariation» ***CommunicationController*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology			
Note	The communication controller is a dedicated hardware device by means of which hosts are sending frames to and receiving frames from the communication medium. **Tags:** vh.latestBindingTime=postBuild			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Subclasses	*AbstractCanCommunicationController*, EthernetCommunicationController, FlexrayCommunicationController, *LinCommunicationController*, UserDefinedCommunicationController			
Aggregated by	EcuInstance.commController, MachineDesign.communicationController			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
wakeUpByControllerSupported	Boolean	0..1	attr	Defines whether the ECU shall be woken up by this CommunicationController. TRUE: wake up is possible FALSE: wake up is not supported Note: If wakeUpByControllerSupported is set to TRUE the feature shall be supported by both hardware and basic software.

Table 3.3: CommunicationController

An EcuInstance may be connected to the same PhysicalChannel via two or more CommunicationControllers. In most cases each of these CommunicationControllers will have a dedicated CommunicationConnector.

There may be rare use cases where an EcuInstance is connected to a PhysicalChannel by one CommunicationController that in turn uses more than one CommunicationConnector.

3.1.3 Communication Connector

[TPS_SYST_01009] Definition of CommunicationConnector

Upstream requirements: RS_SYST_00013

⌈An EcuInstance uses CommunicationConnector elements in order to describe its bus interfaces and to specify the sending/receiving behavior.⌋

The relationship between an EcuInstance, a CommunicationController, and a PhysicalChannel is expressed by letting a PhysicalChannel reference a CommunicationConnector (which in turn is aggregated by EcuInstance) and which also has the ability to reference a CommunicationController.

[constr_5398] Existence of CommunicationConnector.commController

Imposition time: IT_SysDesc

⌈For each CommunicationConnector, the reference in the role commController shall exist.⌋

Class	*CommunicationConnector* (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology			
Note	The connection between the referencing ECU and the referenced channel via the referenced controller. Connectors are used to describe the bus interfaces of the ECUs and to specify the sending/receiving behavior. Each CommunicationConnector has a reference to exactly one communicationController. Note: Several CommunicationConnectors can be assigned to one PhysicalChannel in the scope of one ECU Instance.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Subclasses	*AbstractCanCommunicationConnector*, EthernetCommunicationConnector, FlexrayCommunicationConnector, LinCommunicationConnector, UserDefinedCommunicationConnector			
Aggregated by	EcuInstance.connector, MachineDesign.communicationConnector			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
commController	CommunicationController	0..1	ref	Reference to the communication controller. The CommunicationConnector and referenced CommunicationController shall be aggregated by the same ECUInstance. The communicationController can be referenced by several CommunicationConnector elements. This is important for the FlexRay Bus. FlexRay communicates via two physical channels. But only one controller in an ECU is responsible for both channels. Thus, two connectors (for channel A and for channel B) shall reference to the same controller.
createEcuWakeupSource	Boolean	0..1	attr	If this parameter is available and set to true then a channel wakeup source shall be created for the Physical Channel referencing this CommunicationConnector.
dynamicPncToChannelMappingEnabled	Boolean	0..1	attr	Defines if this EcuInstance shall implement the dynamic PNC-to-channel-mapping functionality on this CommunicationConnector and its respective Physical Channel. **Tags:** atp.Status=draft
ecuCommPortInstance	CommConnectorPort	*	aggr	An ECUs reception or send ports. atpVariation: If signals/PDUs/frames are variable, the corresponding ports shall be variable, too. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=ecuCommPortInstance.shortName, ecuCommPortInstance.variationPoint.shortLabel vh.latestBindingTime=postBuild
pncFilterArrayMask (ordered)	PositiveInteger	*	attr	Bit mask for NM-Pdu Payload used to configure the NM filter mask for the Network Management.
pncGatewayType	PncGatewayTypeEnum	0..1	attr	Defines if this EcuInstance shall implement the PncGateway functionality on this CommunicationConnector and its respective PhysicalChannel. Several EcuInstances on the same PhysicalChannel can have the PncGateway functionality enabled, but only one of them shall have the pncGatewayType "active".

Table 3.4: CommunicationConnector

Enumeration	PncGatewayTypeEnum
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology
Note	Defines the PncGateway roles.
Aggregated by	*CommunicationConnector*.pncGatewayType
Literal	**Description**

▽

△

Enumeration	**PncGatewayTypeEnum**
active	The active PncGateway functionality shall be performed **Tags:** atp.EnumerationLiteralIndex=0
none	No PncGateway functionality shall be performed **Tags:** atp.EnumerationLiteralIndex=1
passive	The passive PncGateway functionality shall be performed **Tags:** atp.EnumerationLiteralIndex=2

Table 3.5: PncGatewayTypeEnum

Note: Use-case for the relation of several CommunicationConnectors assigned to one PhysicalChannel in the scope of one EcuInstance: One safety measure for a safety relevant ECU can be to have two transceivers (and two controllers) connected to the same network (Bus). In case a safety violation is detected one transceiver can be disabled and the respective Frames are blocked. The other transceiver stays active and keeps the ECU alive for diagnostics.

The CommunicationConnector.pncFilterArrayMask is configured per communication connector. This data mask is calculated over the whole payload of the NmPdu ignoring the leading bytes which do not contain pncVector information. The number of leading bytes which shall be ignored is equivalent to the value of System.pncVectorOffset.

The CommunicationConnector.pncFilterArrayMask is an ordered list of byte (uint8) values which represent the PNC Vector layout.

The number of list elements corresponds to NmCluster.pncClusterVectorLength, if defined, or System.pncVectorLength

[constr_3685] Allowed values for each element of pncFilterArrayMask

Imposition time: IT_SysDesc

⌈The value for each element of CommunicationConnector.pncFilterArrayMask shall be in the range between 0 and 255.⌋

[constr_3686] Allowed number of entries for pncFilterArrayMask

Imposition time: IT_SysDesc

⌈The number of CommunicationConnector.pncFilterArrayMask elements shall be:

- NmCluster.pncClusterVectorLength, if defined
- System.pncVectorLength, otherwise.

⌋

3.1.4 Internal ECU handling upon a communication wakeup

An ECU may be woken up via communication activities on a communication bus / network. It is possible to define the expected behavior if communication wakeup has been qualified as valid:

- If EcuInstance.channelSynchronousWakeup is set to TRUE, then all channels and all configured PNCs are woken up upon a detection of a valid wakeup on a channel
- If EcuInstance.pncSynchronousWakeup is set to TRUE, then all PNCs and the corresponding channels are woken up upon a detection of a valid wakeup on a channel.

A wakeup indication shall be forwarded to the ECU State Manager to perform the according wakeup handling. Therefore so-called wakeup sources can be configured. A wakeup source can be referenced by one or multiple channels. The wakeup source itself can reference multiple PNCs or channels. Therefore it is possible by the ECU State Manager to detect a wakeup on one channel and forward the wakeup indication to other channels or PNCs. Additionally, the Communication Manager provides the possibility to request all its channels and PNCs if one wakeup has been indicated (EcuInstance.channelSynchronousWakeup set to TRUE). It is possible to derive the wakeup source if CommunicationConnector.createEcuWakeupSource is set to TRUE.

If only a synchronous PNC wakeup is used, then EcuInstance.channelSynchronousWakeup should be set to FALSE and EcuInstance.pncSynchronousWakeup should be set to TRUE. A synchronous PNC wakeup can be achieved by setting CommunicationConnector.createEcuWakeupSource and EcuInstance.pncSynchronousWakeup to TRUE. This derives a wakeup source where all PNCs, which are configured for this EcuInstance, are added.

[constr_3741] Exclusive setting of channelSynchronousWakeup or pncSynchronousWakeup

Imposition time: IT_SysDesc

⌈At most one of EcuInstance.channelSynchronousWakeup or EcuInstance.pncSynchronousWakeup shall be set to TRUE.⌋

The settings of EcuInstance.channelSynchronousWakeup, EcuInstance.pncSynchronousWakeup, and CommunicationConnector.createEcuWakeupSource regulates the creation of wakeup sources and the reference to PNCs and Channels.

If a CommunicationCluster has several PhysicalChannels defined, then for all those PhysicalChannels the attribute createEcuWakeupSource shall be set to the same value in the scope of one EcuInstance.

[constr_3742] Value for createEcuWakeupSource in the conntext of a CommunicationCluster

Imposition time: IT_SysDesc

⌈The attribute CommunicationConnector.createEcuWakeupSource shall be set to the same value for all CommunicationConnectors in the scope of one EcuInstance which are referenced by PhysicalChannels that belong to the same CommunicationCluster.⌋

3.2 Communication Clustering

3.2.1 Communication Cluster

[TPS_SYST_01010] Definition of CommunicationCluster

Upstream requirements: RS_SYST_00013

⌈CommunicationCluster represents a formal way to express that a number of EcuInstances are linked by an arbitrary topology (bus, star, ring, tree). Depending on the communication standard, a CommunicationCluster may either have exactly one or more (redundant) PhysicalChannels.⌋

Note that all ECUs within a CommunicationCluster communicate within the same address range.

Note that the same ECU can participate in more than one CommunicationCluster if it has more than one CommunicationConnector being referenced by PhysicalChannels owned by different CommunicationClusters.

Class	«atpVariation» ***CommunicationCluster*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology			
Note	The CommunicationCluster is the main element to describe the topological connection of communicating ECUs. A cluster describes the ensemble of ECUs, which are linked by a communication medium of arbitrary topology (bus, star, ring, ...). The nodes within the cluster share the same communication protocol, which may be event-triggered, time-triggered or a combination of both. A CommunicationCluster aggregates one or more physical channels. **Tags:** vh.latestBindingTime=postBuild

Table 3.7: PhysicalChannel

3.3 Specialized Attributes of the Topology Entities

According to their characteristic features, different communication standards like FlexRay, CAN, TTCAN, LIN, J1939 and Ethernet have individual attributes that need to be described additionally to the common topology classes. Figure 3.3 shows the specialization of the CommunicationCluster into the more specific FlexrayCluster, CanCluster, TtcanCluster, J1939Cluster, LinCluster and EthernetCluster.

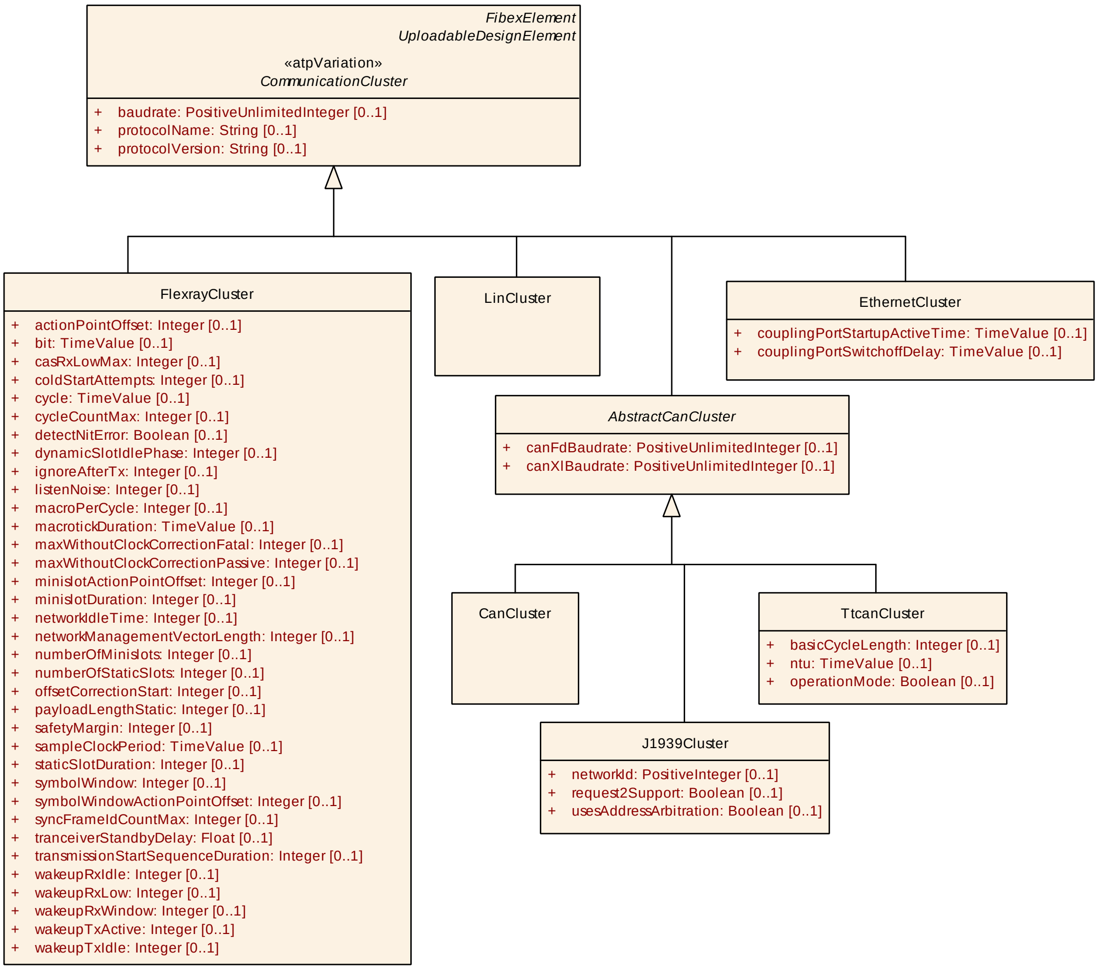

Figure 3.3: Specialized CommunicationCluster attributes (TopologyAttributeRefinement)

3.3.1 CAN

Modeling of the CAN bus is supported in the System Template by the means of four specialized meta-model classes: `CanCluster`, `CanCommunicationController`, `CanPhysicalChannel`, `CanCommunicationConnector` (Figure 3.4).

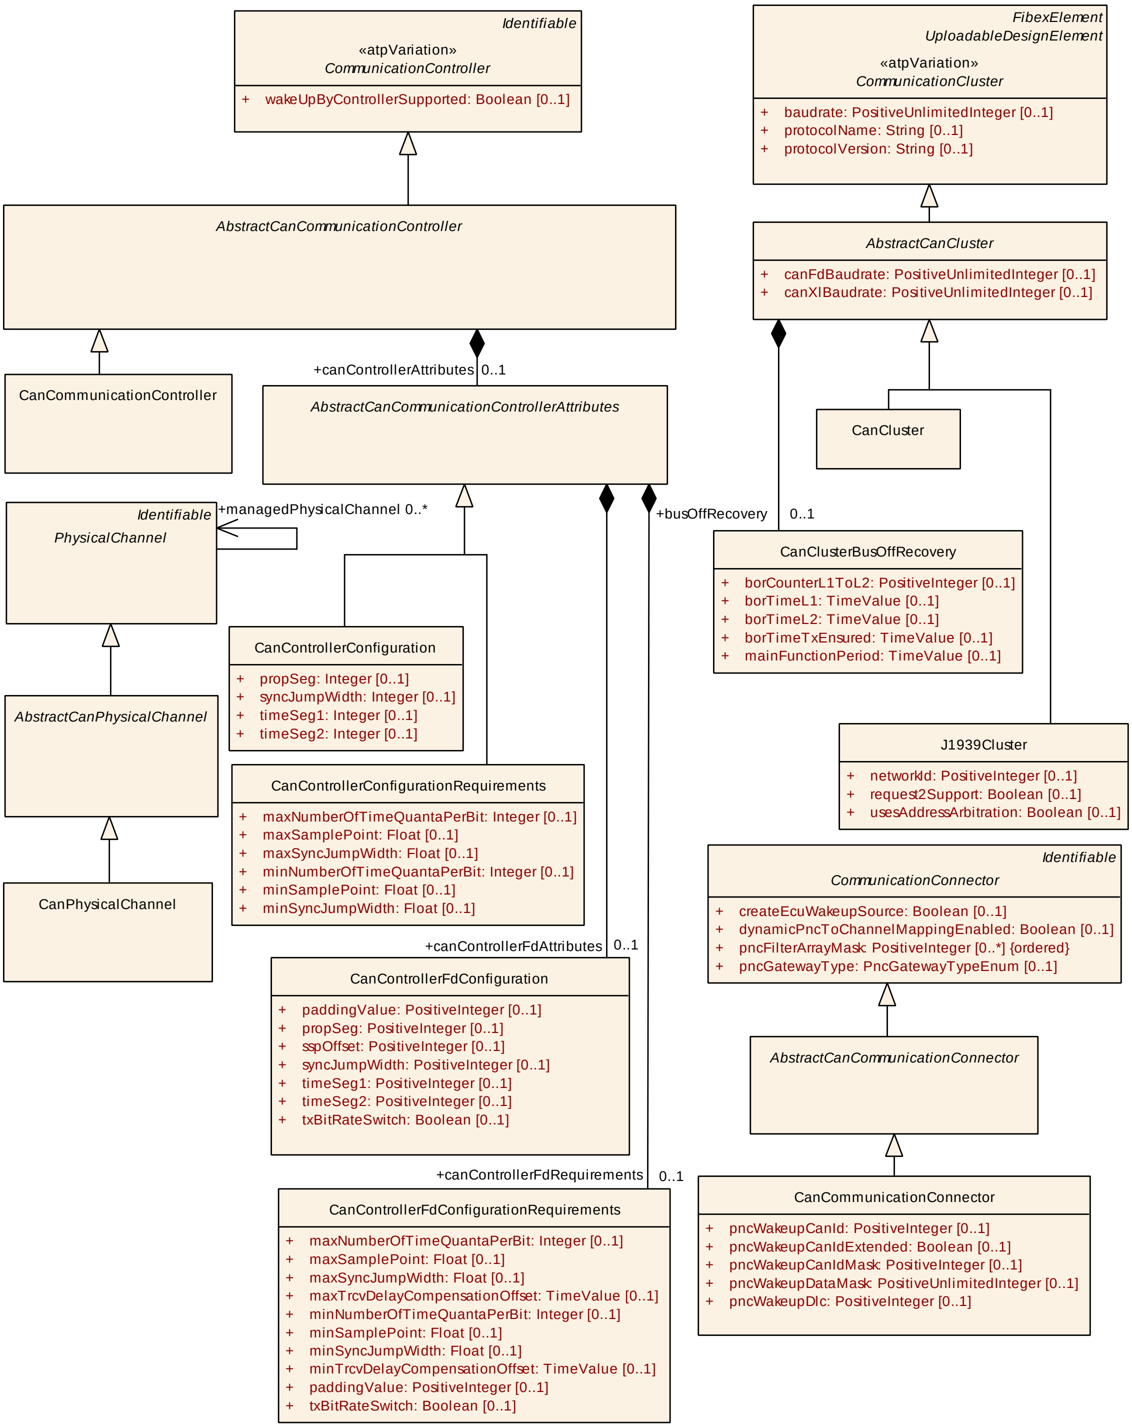

Figure 3.4: CAN bus elements (Fibex4Can_Topology)

3.3.1.1 CAN Cluster

CanCluster specifies the existence of a CAN cluster in the system's physical topology. It contains additional CAN-specific cluster-wide attributes. The common CAN and TTCAN attributes are collected in the AbstractCanCluster class.

3.3.1.2 CAN Communication Controller

CanCommunicationController is a specialization of the abstract CommunicationController class. It contains the specific CAN controller attributes needed for configuring the CAN stack in an ECU connected to a certain CAN cluster. The common CAN and TTCAN attributes are collected in the AbstractCanCommunicationController class. It is possible to specify the CAN Controller configuration parameters as exact values or as requirements that have to be respected by the ECU developer. Therefore the two elements CanControllerConfiguration and CanControllerConfigurationRequirements were created.

Table 3.17: CanControllerFdConfigurationRequirements

3.3.1.2.2 CAN XL

CAN XL - as continued development of CAN FD - is able to carry large data per frame (up to 2048 bytes payload). The type of payload contained in a CAN XL frame is specified by the “SDU Type” field within the CAN XL frame header.

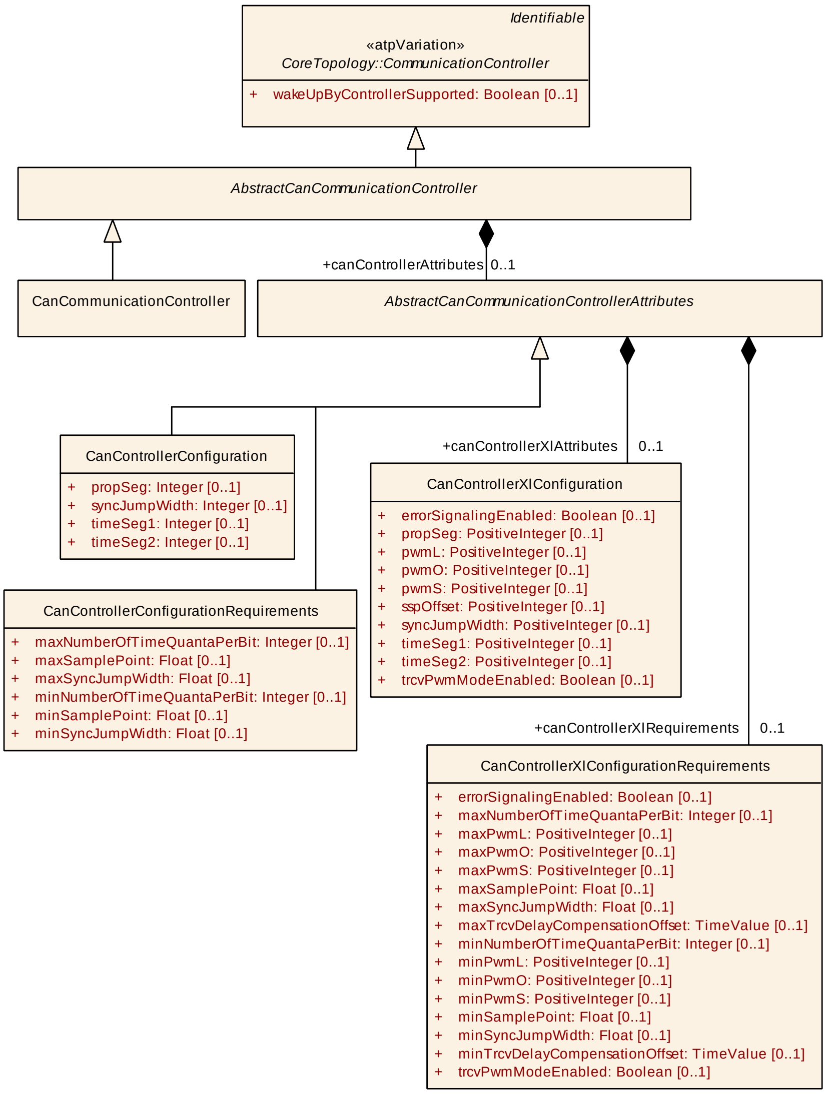

Figure 3.5: CAN XL bus elements

AUTOSAR CP supports the following SDU Type values (as specified by the *CiA* standardization - see Ch. 6.7.3.2) relating to the use cases of CAN XL communication:

1. **SDU Type 0x01h - Content based addressing:** This is equivalent to Classical CAN communication using the CAN XL specific $\mathrm{PDU_N}$ Identifier to denote the content of the CAN frame. For CAN XL, native payload data with up to 2048 bytes is transported in CAN XL frames.

2. **SDU Type 0x02h - Node addressing:** Using the “destination node address” field within the CAN XL frame header, a specific destination node that shall receive the CAN XL frame carrying native payload data is defined.

3. **SDU Type 0x03h - Classical CAN / CAN FD mapped tunneling:** A Classical CAN or CAN FD frame is tunneled inside a CAN XL frame.

4. **SDU Type 0x04h - IEEE 802.3 (Ethernet) tunneling:** An Ethernet frame is tunneled by a CAN XL frame without mapping of addressing information onto the CAN XL frame header.

5. **SDU Type 0x05h - IEEE 802.3 (Ethernet) mapped tunneling:** An Ethernet frame is tunneled by a CAN XL frame with partial mapping of the MAC destination address (4 specific bytes out of 6) and - if defined - the VLAN ID (lower 8 bits out of 12) onto fields of the CAN XL frame header.

6. **SDU Types 0xE0h..0xFEh - Manufacturer specific:** Manufacturer specific CAN XL frames for proprietary use cases.

Please note that for SDU Type 0x05h (Ethernet mapped tunneling), the mapping allows for hardware filtering of a subset of CAN XL frames carrying Ethernet frames which are not relevant for the receiving node. Since the full addressing information (i.e. full MAC address and full VLAN ID) is inside the Ethernet frame, the final reception filtering must be done by software processing of the tunneled Ethernet frame at the receiving node.

For all SDU Types described above, CAN XL requires the definition of CanControllerXlConfiguration or CanControllerXlConfigurationRequirements which contain physical layer related configuration parameters or requirements, respectively, as well as the definition of CanXlFrameTriggeringProps (aggregated by CanFrameTriggering) which contains, amongst others, the sduType attribute.

For the use cases involving Ethernet tunneling (i.e. SDU Types 0x04h and 0x05h), the EthernetCommunicationController is the connecting model element as it establishes - via the reference EthernetCommunicationController.canXlConfig - the link between the CanCommunicationController (which is CAN XL by aggregating a CanControllerXlConfiguration) and the EthernetCommunicationController which represents the lower end of the Ethernet and TCP/IP stack to be connected to the “CAN XL tunnel”. Further details on this tunneling configuration are given in Ch. 3.3.6.4.

Please note that the Ethernet and TCP/IP stack “on top” of EthernetCommunicationController need to be defined in the usual Ethernet and TCP/IP way (including EthernetPhysicalChannel but with the exception of network management - see Ch. 6.9.5.2). By the above mentioned linking to the associated CAN XL based CanCommunicationController, the tunneling is realized and the respective Ethernet frames are sent and received through the associated CAN XL physical channel.

[TPS_SYST_03074] CAN Controller support of CAN XL frames ⌈The specific configuration of CAN controllers for CAN XL frames is supported by the CanControllerXlConfiguration and CanControllerXlConfigurationRequirements elements that are aggregated by AbstractCanCommunicationControllerAttributes.⌋

Please note that the CAN XL specific baudrate is configured by the attribute canXlBaudrate of the abstract element AbstractCanCluster.

minPwmL	PositiveInteger	0..1	attr	Specifies the minimum PWM long phase length.
minPwmO	PositiveInteger	0..1	attr	Specifies the maximum PWM time offset.
minPwmS	PositiveInteger	0..1	attr	Specifies the minimum PWM short phase length.
minSamplePoint	Float	0..1	attr	The min. value of the sample point as a percentage of the total bit time.
minSyncJumpWidth	Float	0..1	attr	The min. Synchronization Jump Width value as a percentage of the total bit time. The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.
minTrcvDelayCompensationOffset	TimeValue	0..1	attr	Specifies the minimum Transceiver Delay Compensation Offset in seconds. If not specified Transceiver Delay Compensation is disabled.
trcvPwmModeEnabled	Boolean	0..1	attr	Specifies if the transceiver shall be set to the PWM mode. TRUE: The transceiver shall be switched to PWM mode. FALSE: The transceiver shall work in classic CAN mode.

Table 3.19: CanControllerXlConfigurationRequirements

For the use cases of tunneling Ethernet frames through CAN XL, specific CAN XL related configurations need to be defined for `EthernetCommunicationController` and `EthernetCommunicationConnector`. Please refer to Ch. 3.3.6.4 and Ch. 3.3.6.5 for the respective configuration details.

3.3.1.3 CAN Physical Channel

CanPhysicalChannel is a specialization of the abstract PhysicalChannel class. It contains the specific CAN PhysicalChannel attributes. The common CAN and TTCAN attributes are collected in the AbstractCanPhysicalChannel class.

Class	***AbstractCanPhysicalChannel*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Can::CanTopology			
Note	Abstract class that is used to collect the common TtCAN and CAN PhysicalChannel attributes.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *PhysicalChannel*, *Referrable*			
Subclasses	CanPhysicalChannel, TtcanPhysicalChannel			
Aggregated by	*CommunicationCluster*.physicalChannel

3.3.1.4 CAN Communication Connector

CanCommunicationConnector is a specialization of the abstract CommunicationConnector class. It contains the specific CAN CommunicationConnector attributes. The common CAN and TTCAN attributes are collected in the AbstractCanCommunicationConnector class.

Class	***AbstractCanCommunicationConnector*** (abstract)
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Can::CanTopology
Note	Abstract class that is used to collect the common TtCAN and CAN CommunicationConnector attributes.
Base	*ARObject*, *CommunicationConnector*, *Identifiable*, *MultilanguageReferrable*, *Referrable*

Attribute	***Type***	***Mult.***	***Kind***	***Note***
pncWakeupCanId	PositiveInteger	0..1	attr	CAN Identifier used to configure the CAN Transceiver for partial network wakeup.
pncWakeupCanIdExtended	Boolean	0..1	attr	Defines whether pncWakeupCanId and pncWakeupCanIdMask shall be interpreted as extended or standard CAN ID.
pncWakeupCanIdMask	PositiveInteger	0..1	attr	Bit mask for CAN Identifier used to configure the CAN Transceiver for partial network wakeup.
pncWakeupDataMask	PositiveUnlimitedInteger	0..1	attr	Bit mask for CAN Payload used to configure the CAN Transceiver for partial network wakeup.
pncWakeupDlc	PositiveInteger	0..1	attr	Data Length of the remote data frame used to configure the CAN Transceiver for partial network wakeup in Bytes.

Table 3.23: CanCommunicationConnector

3.3.2 TTCAN

Modeling of TTCAN clusters is supported in the System Template by the means of four specialized meta-model classes: `TtcanCluster`, `TtcanCommunicationController`, `TtcanCommunicationConnector`, `TtcanPhysicalChannel` (figure 3.6).

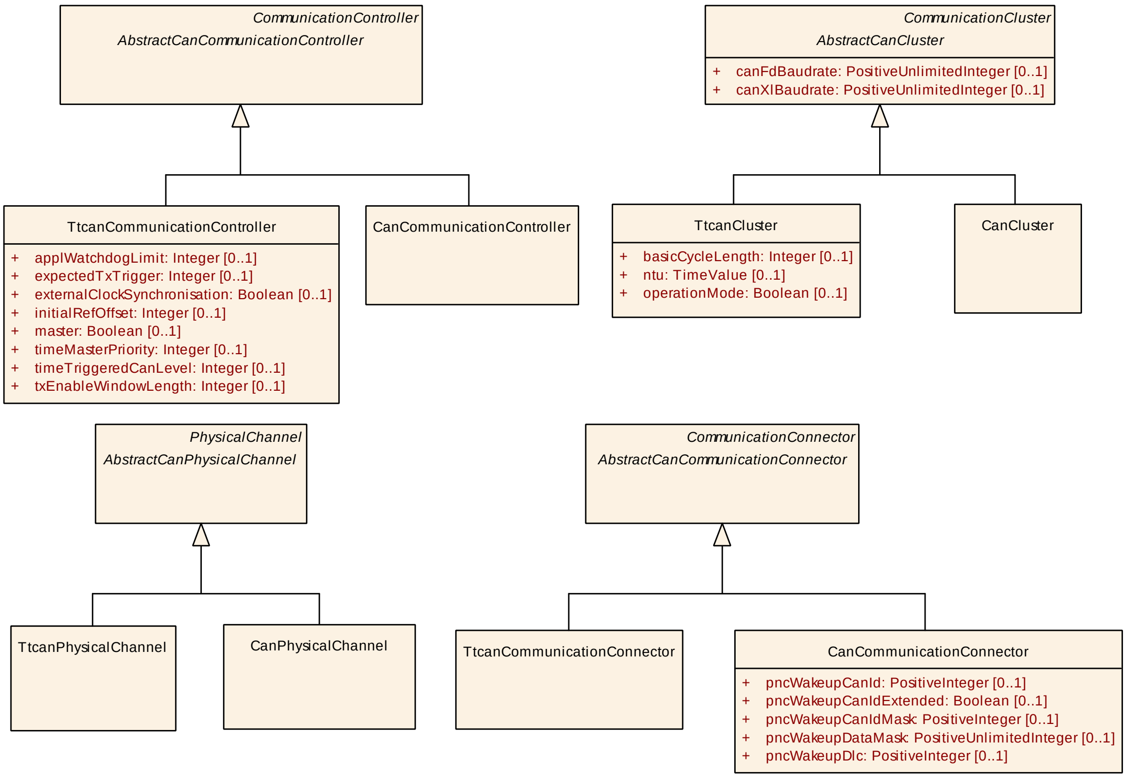

Figure 3.6: TTCAN bus elements (Fibex4Ttcan_Topology)

3.3.2.1 TTCAN Cluster

`TtcanCluster` specifies the existence of a TTCAN cluster in the system's physical topology. Additionally to the common CAN and TTCAN attributes it contains TTCAN-specific cluster-wide attributes.

Class	«atpVariation» **TtcanCluster**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ttcan::TtcanTopology			
Note	TTCAN bus specific cluster attributes. **Tags:** atp.recommendedPackage=CommunicationClusters			
Base	*ARElement*, *ARObject*, *AbstractCanCluster*, *CollectableElement*, *CommunicationCluster*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
basicCycle Length	Integer	0..1	attr	Length of a basic-cycle. Unit: NTUs
ntu	TimeValue	0..1	attr	Unit measuring all times and providing a constant of the whole network. For level 1, this is always the CAN bit time. Unit: seconds.
operationMode	Boolean	0..1	attr	Possible operation modes True: Time-Triggered False: Event-Synchronised-Time-Triggered

Table 3.24: TtcanCluster

3.3.2.2 TTCAN Communication Controller

`TtcanCommunicationController` is a specialization of the `AbstractCanCommunicationController` class. Additionally to the common CAN and TTCAN attributes it contains the specific TTCAN Controller attributes.

Class	«atpVariation» **TtcanCommunicationController**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ttcan::TtcanTopology			
Note	TTCAN bus specific communication port attributes.			
Base	*ARObject*, *AbstractCanCommunicationController*, *CommunicationController*, *Identifiable*, *Multilanguage Referrable*, *Referrable*			
Aggregated by	EcuInstance.commController, MachineDesign.communicationController			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
applWatchdog Limit	Integer	0..1	attr	The Appl_Watchdog_Limit shall be an 8-bit value specifying the period for the application watchdog in Appl_Watchdog_Limit times 256 NTUs.
expectedTx Trigger	Integer	0..1	attr	The Expected_Tx_Trigger shall be an eight (8) bit value which limits the number of messages the FSE may try to transmit in one matrix cycle.
externalClock Synchronisation	Boolean	0..1	attr	One bit shall be used to configure whether or not external clock synchronisation will be allowed during runtime (only Level 2).
initialRefOffset	Integer	0..1	attr	The Initial_Ref_Offset shall be an eight (8) bit value for the initialisation of Ref_Trigger_Offset.
master	Boolean	0..1	attr	One bit shall be used to distinguish between (potential) time masters and time slaves. This can be derived from the frame-triggering's triggers.

▽

△

Class	«atpVariation» **TtcanCommunicationController**			
timeMaster Priority	Integer	0..1	attr	The time master priority shall contain a three bit value for the priority of the current time master (the last three bits of the identifier of the reference message). This can be derived from the frame-triggering's triggers.
timeTriggered CanLevel	Integer	0..1	attr	One bit shall be used to distinguish between Level 1 and Level 2.
txEnable WindowLength	Integer	0..1	attr	The length of the Tx_Enable window shall be a four (4) bit value specifying the length of the time period (1-16 nominal CAN bit times) in which a transmission may be started.

Table 3.25: TtcanCommunicationController

3.3.2.3 TTCAN Physical Channel

TtcanPhysicalChannel is a specialization of the AbstractCanPhysicalChannel class. Additionally to the common CAN and TTCAN attributes it contains the specific TTCAN Physical Channel attributes.

Class	**TtcanPhysicalChannel**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ttcan::TtcanTopology			
Note	TTCAN bus specific physical channel attributes.			
Base	*ARObject*, *AbstractCanPhysicalChannel*, *Identifiable*, *MultilanguageReferrable*, *PhysicalChannel*, *Referrable*			
Aggregated by	*CommunicationCluster*.physicalChannel			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
–	–	–	–	–

Table 3.26: TtcanPhysicalChannel

3.3.2.4 TTCAN Communication Connector

TtcanCommunicationConnector is a specialization of the AbstractCanCommunicationConnector class. Additionally to the common CAN and TTCAN attributes it contains the specific TTCAN CommunicationConnector attributes.

Class	**TtcanCommunicationConnector**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ttcan::TtcanTopology			
Note	TTCAN bus specific communication connector attributes.			
Base	*ARObject*, *AbstractCanCommunicationConnector*, *CommunicationConnector*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EcuInstance.connector, MachineDesign.communicationConnector			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
–	–	–	–	–

Table 3.27: TtcanCommunicationConnector

3.3.3 SAE J1939

Modeling of J1939 Communication Clusters is supported in the System Template with the J1939Cluster element that is derived from AbstractCanCluster (see figure 3.4).

Class	«atpVariation» **J1939Cluster**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Can::CanTopology			
Note	J1939 specific cluster attributes. **Tags:** atp.recommendedPackage=CommunicationClusters			
Base	*ARElement*, *ARObject*, *AbstractCanCluster*, *CollectableElement*, *CommunicationCluster*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
networkId	PositiveInteger	0..1	attr	This represents the network ID for the J1939 cluster.
re-quest2Support	Boolean	0..1	attr	Enables support for the Request2 PGN (RQST2).
usesAddress Arbitration	Boolean	0..1	attr	Defines whether the nodes attached to this channel use an initial address claim, and whether they react to contending address claims of other nodes. True: The initial address claim is sent, and the node reacts to address claims of other nodes. False: The node only sends an address claim upon request, and does not care for contending address claims.

Table 3.28: J1939Cluster

To describe the communication on a J1939Cluster CanFrameTriggerings are used that are aggregated by a CanPhysicalChannel.

[constr_3050] J1939Cluster uses exactly one CanPhysicalChannel

Imposition time: IT_SysDesc

⌈A J1939Cluster shall aggregate exactly one CanPhysicalChannel.⌋

[constr_1463] Applicable values for J1939Cluster.networkId

Imposition time: IT_SysDesc

⌈The values of the attribute J1939Cluster.networkId shall always be within the interval 1..4.⌋

Please note that AUTOSAR supports only the four mentioned bus types. Still, an implementation could e.g. support J1708 [13] by means of a complex driver and would then need to assign the corresponding bus type.

3.3.4 FlexRay

Modeling of FlexRay clusters is supported in the System Template by the means of four specialized meta-model classes: `FlexrayCluster`, `FlexrayCommunicationConnector`, `FlexrayPhysicalChannel`, `FlexrayCommunicationController` (Figure 3.7).

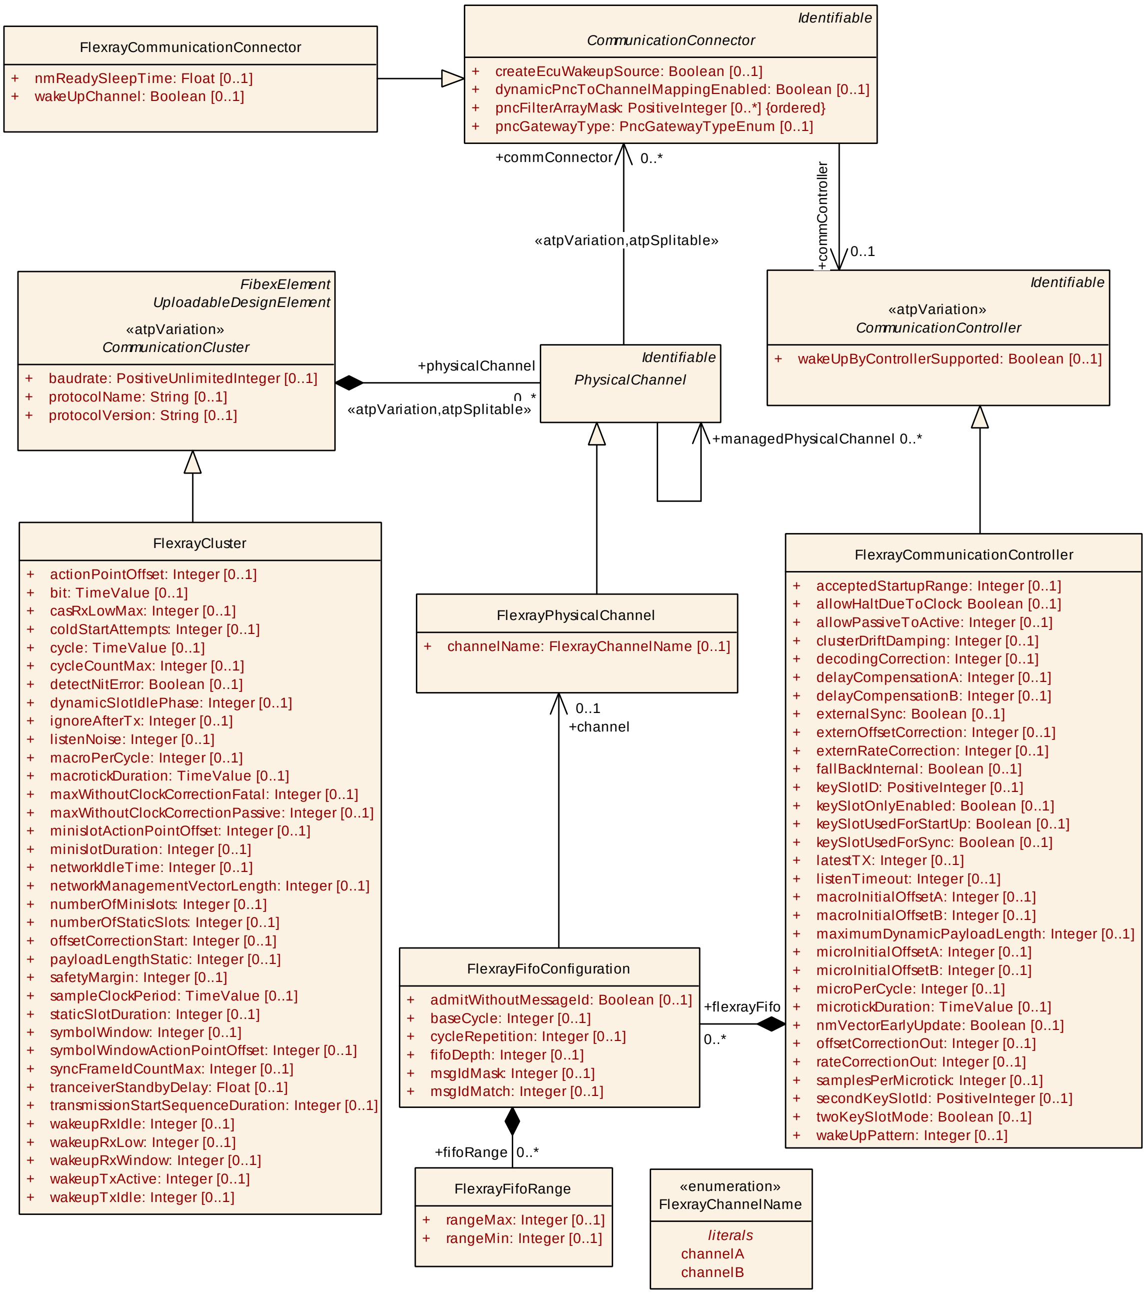

Figure 3.7: FlexRay cluster elements (Fibex4FlexRay_Topology)

3.3.4.1 FlexRay Cluster

FlexrayCluster specifies the existence of a FlexRay cluster in the system's physical topology. It contains additional FlexRay-specific cluster-wide attributes.

Class	«atpVariation» **FlexrayCluster**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Flexray::FlexrayTopology			
Note	FlexRay specific attributes to the physicalCluster **Tags:** atp.recommendedPackage=CommunicationClusters			
Base	*ARElement*, *ARObject*, *CollectableElement*, *CommunicationCluster*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
actionPointOffset	Integer	0..1	attr	The offset of the action point in networks
bit	TimeValue	0..1	attr	Nominal bit time (= 1 / fx:SPEED). gdBit = cSamplesPerBit * gdSampleClockPeriod. Unit: seconds (gdBit)
casRxLowMax	Integer	0..1	attr	Upper limit of the Collision Avoidance Symbol (CAS) acceptance window. Unit:bitDuration
coldStartAttempts	Integer	0..1	attr	The maximum number of times that a node in this cluster is permitted to attempt to start the cluster by initiating schedule synchronization
cycle	TimeValue	0..1	attr	Length of the cycle. Unit: seconds
cycleCountMax	Integer	0..1	attr	Maximum cycle counter value in a given cluster. Remark: Set to 63 for FlexRay Protocol 2.1 Rev. A compliance.
detectNitError	Boolean	0..1	attr	Indicates whether NIT error status of each cluster shall be detected or not.
dynamicSlotIdlePhase	Integer	0..1	attr	The duration of the dynamic slot idle phase in minislots.
ignoreAfterTx	Integer	0..1	attr	Duration for which the bitstrobing is paused after transmission [gdBit].
listenNoise	Integer	0..1	attr	Upper limit for the start up and wake up listen timeout in the presence of noise. Expressed as a multiple of the cluster constant pdListenTimeout. Unit microticks
macroPerCycle	Integer	0..1	attr	The number of macroticks in a communication cycle
macrotickDuration	TimeValue	0..1	attr	Duration of the cluster wide nominal macrotick, expressed in s.
maxWithoutClockCorrectionFatal	Integer	0..1	attr	Threshold concerning vClockCorrectionFailedCounter. Defines the number of consecutive even/odd Cycle pairs with missing clock correction terms that will cause the protocol to transition from the POC:normal active or POC:normal passive state into the POC:halt state.
maxWithoutClockCorrectionPassive	Integer	0..1	attr	Threshold concerning vClockCorrectionFailedCounter. Defines the number of consecutive even/odd Cycle pairs with missing clock correction terms that will cause the protocol to transition from the POC:normal active state to the POC:normal passive state.
minislotActionPointOffset	Integer	0..1	attr	The Offset of the action point within a minislot. Unit: macroticks
minislotDuration	Integer	0..1	attr	The duration of a minislot (dynamic segment). Unit: macroticks.
networkIdleTime	Integer	0..1	attr	The duration of the network idle time in macroticks

▽

△

Class	«atpVariation» **FlexrayCluster**			
network Management VectorLength	Integer	0..1	attr	Length of the Network Management vector in a cluster [bytes]
numberOf Minislots	Integer	0..1	attr	Number of Minislots in the dynamic segment.
numberOfStatic Slots	Integer	0..1	attr	The number of static slots in the static segment.
offsetCorrection Start	Integer	0..1	attr	Start of the offset correction phase within the Network Idle Time (NIT), expressed as the number of macroticks from the start of cycle. Unit: macroticks
payloadLength Static	Integer	0..1	attr	Globally configured payload length of a static frame. Unit: 16-bit WORDS.
safetyMargin	Integer	0..1	attr	Additional timespan in macroticks which takes jitter into account to be able to set the JobListPointer to the next possible job which can be executed in case the FlexRay Job List Execution Function has be resynchronized.
sampleClock Period	TimeValue	0..1	attr	Sample clock period. Unit: seconds
staticSlot Duration	Integer	0..1	attr	The duration of a slot in the static segment. Unit: macroticks
symbolWindow	Integer	0..1	attr	The duration of the symbol window. Unit: macroticks
symbolWindow ActionPoint Offset	Integer	0..1	attr	Number of macroticks the action point offset is from the beginning of the symbol window [Macroticks].
syncFrameId CountMax	Integer	0..1	attr	Maximum number of distinct syncframe identifiers present in a given cluster. This parameter maps to FlexRay Protocol 2.1 Rev. A parameter gSyncNodeMax.
tranceiver StandbyDelay	Float	0..1	attr	The duration of timer t_TrcvStdbyDelay in seconds. The granularity of this parameter shall be restricted to full Flex Ray cycles (cycle). The transceiver status setting to STANDBY shall be delayed by this value. Not specifying a value or a value of 0 shall imply that the timer is not used.
transmission StartSequence Duration	Integer	0..1	attr	Number of bits in the Transmission Start Sequence [gd Bits].
wakeupRxIdle	Integer	0..1	attr	Number of bits used by the node to test the duration of the 'idle' or HIGH phase of a received wakeup. Unit:bit Duration Remarks: This parameter maps to FlexRay Protocol 2.1 Rev. A parameter gdWakeupSymbolRxIdle.
wakeupRxLow	Integer	0..1	attr	Number of bits used by the node to test the duration of the LOW phase of a received wakeup. Unit:bitDuration Remarks: This parameter maps to FlexRay Protocol 2.1 Rev. A parameter gdWakeupSymbolRxLow.
wakeupRx Window	Integer	0..1	attr	The size of the window used to detect wakeups [gdBit]. Remarks: This parameter maps to FlexRay Protocol 2.1 Rev. A parameter gdWakeupSymbolRxWindow.
wakeupTxActive	Integer	0..1	attr	Number of bits used by the node to transmit the LOW phase of awakeup symbol and the HIGH and LOW phases of a WUDOP. Unit:bitDuration
wakeupTxIdle	Integer	0..1	attr	Number of bits used by the node to transmit the 'idle' part of a wakeup symbol. Unit: gDbit

Table 3.29: FlexrayCluster

3.3.4.2 FlexRay Communication Controller

FlexrayCommunicationController is a specialization of the Communication-Controller class. It contains the specific FlexRay controller attributes needed for configuring the FlexRay stack in an ECU connected to a certain FlexRay cluster.

Class	«atpVariation» **FlexrayCommunicationController**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Flexray::FlexrayTopology			
Note	FlexRay bus specific communication port attributes.			
Base	*ARObject*, *CommunicationController*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EcuInstance.commController, MachineDesign.communicationController			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
accepted StartupRange	Integer	0..1	attr	Expanded range of measured clock deviation allowed for startup frames during integration. Unit:microtick
allowHaltDueTo Clock	Boolean	0..1	attr	Boolean flag that controls the transition to the POC:halt state due to a clock synchronization errors. If set to true, the Communication Controller is allowed to transition to POC:halt. If set to false, the Communication Controller will not transition to the POC:halt state but will enter or remain in the normal POC (passive State).
allowPassiveTo Active	Integer	0..1	attr	Number of consecutive even/odd cycle pairs that shall have valid clock correction terms before the Communication Controller will be allowed to transition from the POC:normal passive state to POC:normal active state. If set to 0, the Communication Controller is not allowed to transition from POC:norm

▽

△

Class	«atpVariation» **FlexrayCommunicationController**			
clusterDrift Damping	Integer	0..1	attr	The cluster drift damping factor used in clock synchronization rate correction in microticks
decoding Correction	Integer	0..1	attr	Value used by the receiver to calculate the difference between primary time reference point and secondary time reference point. Unit: Microticks (pDecodingCorrection)
delay CompensationA	Integer	0..1	attr	Value used to compensate for reception delays on channel A Unit: Microticks. This optional parameter shall only be filled out if channel A is used.
delay CompensationB	Integer	0..1	attr	Value used to compensate for reception delays on channel B. Unit: Microticks. This optional parameter shall only be filled out if channel B is used.
externalSync	Boolean	0..1	attr	Flag indicating whether the node is externally synchronized (operating as Time Gateway Sink in an TT-E Time Triggered External Sync cluster) or locally synchronized.
externOffset Correction	Integer	0..1	attr	Fixed amount added or subtracted to the calculated offset correction term to facilitate external offset correction, expressed in node-local microticks.
externRate Correction	Integer	0..1	attr	Fixed amount added or subtracted to the calculated rate correction term to facilitate external rate correction, expressed in node-local microticks.
fallBackInternal	Boolean	0..1	attr	Flag indicating whether a Time Gateway Sink node will switch to local clock operation when synchronization with the Time Gateway Source node is lost (pFallBackInternal = true) or will instead go to POC:ready (pFallBackInternal = false).
flexrayFifo	FlexrayFifo Configuration	*	aggr	One First In First Out (FIFO) queued receive structure, defining the admittance criteria to the FIFO.
keySlotID	PositiveInteger	0..1	attr	ID of the slot used to transmit the startup frame, sync frame, or designated single slot frame. If the attributes keySlotUsedForStartUp, keySlotUsedForSync, or keySlot OnlyEnabled are set to true the key slot value is mandatory.
keySlotOnly Enabled	Boolean	0..1	attr	Flag indicating whether or not the node shall enter key slot only mode following startup.
keySlotUsedFor StartUp	Boolean	0..1	attr	Flag indicating whether the Key Slot is used to transmit a startup frame.
keySlotUsedFor Sync	Boolean	0..1	attr	Flag indicating whether the Key Slot is used to transmit a sync frame.
latestTX	Integer	0..1	attr	The number of the last minislot in which a transmission can start in the dynamic segment for the respective node
listenTimeout	Integer	0..1	attr	Value for the startup listen timeout and wakeup listen timeout. Although this is a node local parameter, the real time equivalent of this value should be the same for all nodes in the cluster. Unit: Microticks
macroInitial OffsetA	Integer	0..1	attr	Integer number of macroticks between the static slot boundary and the closest macrotick boundary of the secondary time reference point based on the nominal macrotick duration. (pMacroInitialOffset). This optional parameter shall only be filled out if channel A is used.
macroInitial OffsetB	Integer	0..1	attr	Integer number of macroticks between the static slot boundary and the closest macrotick boundary of the secondary time reference point based on the nominal macrotick duration. (pMacroInitialOffset). This optional parameter shall only be filled out if channel B is used.

▽

△

Class	«atpVariation» **FlexrayCommunicationController**			
maximumDynamicPayloadLength	Integer	0..1	attr	Maximum payload length for the dynamic channel of a frame in 16 bit WORDS.
microInitialOffsetA	Integer	0..1	attr	Number of microticks between the closest macrotick boundary described by gMacroInitialOffset and the secondary time reference point. The parameter depends on pDelayCompensationA and therefore it has to be set independently for each channel. This optional parameter shall only be filled out if channel A is used.
microInitialOffsetB	Integer	0..1	attr	Number of microticks between the closest macrotick boundary described by gMacroInitialOffset and the secondary time reference point. The parameter depends on pDelayCompensationB and therefore it has to be set independently for each channel. This optional parameter shall only be filled out if channel B is used.
microPerCycle	Integer	0..1	attr	The nominal number of microticks in a communication cycle
microtickDuration	TimeValue	0..1	attr	Duration of a microtick. This attribute can be derived from samplePerMicrotick and gdSampleClockPeriod. Unit: seconds
nmVectorEarlyUpdate	Boolean	0..1	attr	Flag indicating when the update of the Network Management Vector in the CHI shall take place. If set to false, the update shall take place after the NIT. If set to true, the update shall take place after the end of the static segment.
offsetCorrectionOut	Integer	0..1	attr	Magnitude of the maximum permissible offset correction value. Unit:microtick (pOffsetCorrectionOut)
rateCorrectionOut	Integer	0..1	attr	Magnitude of the maximum permissible rate correction value and the maximum drift offset between two nodes operating with unsynchronized clocks for one communication cycle. Unit:Microticks (pRateCorrectionOut) Remarks: This parameter maps to FlexRay Protocol 2.1 Rev. A parameter pdMaxDrift.
samplesPerMicrotick	Integer	0..1	attr	Number of samples per microtick
secondKeySlotId	PositiveInteger	0..1	attr	ID of the second Key slot, in which a second startup frame shall be sent in TT-L Time Triggered Local Master Sync or TT-E Time Triggered External Sync mode. If this parameter is set to zero the node does not have a second key slot.
twoKeySlotMode	Boolean	0..1	attr	Flag indicating whether node operates as a startup node in a TT-E Time Triggered External Sync or TT-L Time Triggered Local Master Sync cluster.
wakeUpPattern	Integer	0..1	attr	Number of repetitions of the Tx-wakeup symbol to be sent during the CC_WakeupSend state of this Node in the cluster

3.3.5.3 LIN Master

LinMaster describes the existence of a LIN master task in a LIN topology node. As such it contains the attributes specific to a LIN master task.

Class	«atpVariation» **LinMaster**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinTopology			
Note	Describing the properties of the refering ecu as a LIN master.			
Base	*ARObject*, *CommunicationController*, *Identifiable*, *LinCommunicationController*, *Multilanguage Referrable*, *Referrable*			
Aggregated by	EcuInstance.commController, MachineDesign.communicationController			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
linSlave	LinSlaveConfig	*	aggr	LinSlaves that are handled by the LinMaster.
timeBase	TimeValue	0..1	attr	Time base is mandatory for the master. It is not used for slaves. LIN 2.0 Spec states: "The time_base value specifies the used time base in the master node to generate the maximum allowed frame transfer time." The time base shall be specified AUTOSAR conform in seconds.
timeBaseJitter	TimeValue	0..1	attr	The attribute timeBaseJitter is a mandatory attribute for the master and not used for slaves. LIN 2.0 Spec states: "The jitter value specifies the differences between the maximum and minimum delay from time base start point to the frame header sending start point (falling edge of BREAK signal)." The jitter shall be specified AUTOSAR conform in seconds.

Table 3.38: LinMaster

Class	LinSlaveConfig			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinTopology			
Note	Node attributes of LIN slaves that are handled by the LinMaster. In the System Description LIN slaves may be described in the context of the Lin Master. In an ECU Extract of the LinMaster the LinSlave Ecus shall not be available. The information that is described here is necessary in the ECU Extract for the configuration of the Lin Master. The values of attributes of LinSlaveConfig and the corresponding LinSlave shall be identical (if both are defined in a System Description).			
Base	*ARObject*			
Aggregated by	LinMaster.linSlave			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
configuredNad	Integer	0..1	attr	To distinguish LIN slaves that are used twice or more within the same cluster.
functionId	PositiveInteger	0..1	attr	LIN function ID.
ident	LinSlaveConfigIdent	0..1	aggr	This adds the ability to become referrable to LinSlave Config.
initialNad	Integer	0..1	attr	Initial NAD of the LIN slave.
linConfigurable Frame	LinConfigurableFrame	*	aggr	List of all frames that are processed by the slave node
linError Response	LinErrorResponse	0..1	aggr	Each slave node shall publish one response error in one of its transmitted unconditional frames.
linOrdered Configurable Frame	LinOrderedConfigurable Frame	*	aggr	List of all frames (unconditional frames, event-triggered frames and sporadic frames) processed by the slave node. This element is necessary for the LIN 2.1 Assign-Frame-PID-Range command.
protocolVersion	String	0..1	attr	Version specifier for a communication protocol. Protocol version of the LinMaster and the LinSlaves may be different.
supplierId	PositiveInteger	0..1	attr	LIN Supplier ID.
variantId	PositiveInteger	0..1	attr	Specifies the Variant ID.

Table 3.39: LinSlaveConfig

Class	LinSlaveConfigIdent

[constr_1655] The mutual existence of LinMasters in the LinSlave EcuExtract

Imposition time: IT_EcuExt

⌈A LinMaster shall not be part of the EcuExtract of a corresponding LinSlave.⌋

[TPS_SYST_02101] Usage of LinSlaveConfig in Ecu Extract

Upstream requirements: RS_SYST_00022

⌈In order to configure LinMaster in a System with category ECU_EXTRACT the LinSlaveConfig aggregated by the LinMaster shall be used.⌋

Please note that, in concordance with [TPS_SYST_02101], even if the LinSlave **can** be modeled independently of the LinMaster it still makes sense that the configuration of the LinMaster **positively contains the aggregation of the LinSlaveConfig** in the role linSlave.

In other words, the configuration of a LinMaster is **not affected** by the question of whether or not the LinSlave is explicitly modeled.

This statement is valid for both the existence of the LinMaster in a System of category SYSTEM_DESCRIPTION or in a System of category ECU_EXTRACT.

The actual correspondence between a Lin slave described by means of the LinSlaveConfig and the actual model of the LinSlave shall be determined by identifying pairs of LinSlaveConfig and LinSlave with an identical set of the attributes that are equally named in both meta-classes. This rule does not apply for the shortName.

Another relevant condition for finding pairs of corresponding LinSlaveConfig and LinSlave is obviously that the LinMaster that aggregates the LinSlaveConfig shall be connected to the same LinCluster to which the corresponding LinSlave is connected.

Of course, this condition can only be checked in the context of a System of category SYSTEM_DESCRIPTION or perhaps SYSTEM_EXTRACT.

3.3.5.4 LIN Slave

AUTOSAR supports the definition of a stand-alone LIN slave[1]. In other words, it is possible to define an ECU Extract that contains the modeling of a LIN slave independently of the modeling of the LIN master.

That said, the ability to define properties of the LIN slave in the context of the LIN master in the form of LinMaster.linSlave still exists and can be used where applicable.

[1] In former versions of this specification document the properties of a LIN slave could only be defined in the context of the corresponding LIN master

[TPS_SYST_05018] Semantics of meta-class LinSlave

Upstream requirements: RS_SYST_00022

⌈Meta-class LinSlave describes the existence of a LIN slave task in a LIN topology node. It describes the attributes of a single LIN slave node.⌋

[TPS_SYST_05019] Semantics of LinErrorResponse.responseError

Upstream requirements: RS_SYST_00022

⌈Each Lin slave has the ability to set an error bit in the response part of one specific LinUnconditionalFrame in the event of errors occurring on frame level. The error bit is modeled by means of a reference to an ISignalTriggering in the role LinErrorResponse.responseError.⌋

Please note that because the response error bit applies for frame errors the responsibility for setting the response error bit lies exclusively at the LinIf.

In the event of such an error, the LinIf on the Lin slave Ecu calls Com_SendSignal() to set the value of the response error bit if applicable[2] and thus the system model needs to foresee the existence of an ISignalTriggering for this purpose.

Aside: on the Lin master, typically a piece of application software picks up the received error bit and uses it to e.g. increment a counter for debouncing purposes. If the counter exceeds a certain value in e.g. a given time interval the Lin master has to assume that a serious problem exists in the communication with this specific slave and react accordingly.

In terms of modeling, this means that if formally modeled application software on the Lin master exists that processes the error response bit (the receiving side of the error response bit) then a DataMapping to a SystemSignal that carries the response error bit needs to be defined.

It is important to understand that application software on a Lin slave positively has no business of setting the value of the response error bit. In other words: on the sending side (i.e. the Lin slave), the application software is not affected and therefore there shall not be a DataMapping on the sending side. This relation motivates the existence of [constr_1656].

[2] In principle, the LinIf on the Lin slave Ecu could directly patch the value of the response error bit into a Tx Pdu before sending but in this case the LinIf would have to pick the correct Pdu and patch it accordingly. In other words, the LinIf would replicate a certain amount of Com functionality. the usage of an ISignalTriggering significantly simplifies the implementation of the LinIf.

[constr_1656] No application-level write access to LinErrorResponse.responseError on Lin slave

Imposition time: IT_SysDesc

⌈The SystemSignal referenced in the role systemSignal by the ISignal referenced by the ISignalTriggering that in turn is referenced in the role LinErrorResponse.responseError shall not be referenced by a DataMapping that allows for writing to the SystemSignal.⌋

Class	«atpVariation» **LinSlave**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinTopology			
Note	Describing the properties of the referring ecu as a LIN slave.

busIdleTimeout Period	TimeValue	0..1	attr	This attribute shall be used to set an idle timeout period for the enclosing LinPhysicalChannel.
scheduleTable	LinScheduleTable	*	aggr	Schedule tables organize the timings of the frames for LIN. atpVariation: If the transmitted frames are variable, the corresponding ScheduleTables shall be variable, too. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=scheduleTable.shortName, schedule Table.variationPoint.shortLabel vh.latestBindingTime=postBuild

Table 3.46: LinPhysicalChannel

[constr_3015] Number of LIN channels

Imposition time: IT_SysDesc

⌈LIN clusters shall aggregate exactly one LinPhysicalChannel.⌋

3.3.6 Ethernet

The EthernetCluster represents an Ethernet network which may consist of several ECUs connected.

An essential aspect of modern Ethernet is the possibility to introduce Ethernet switches in order to partition the EthernetCluster into segments which are used for point-to-point communication between the respective partners. It is possible to define the behavior of such Ethernet switches, this is described in chapter 3.3.6.6.

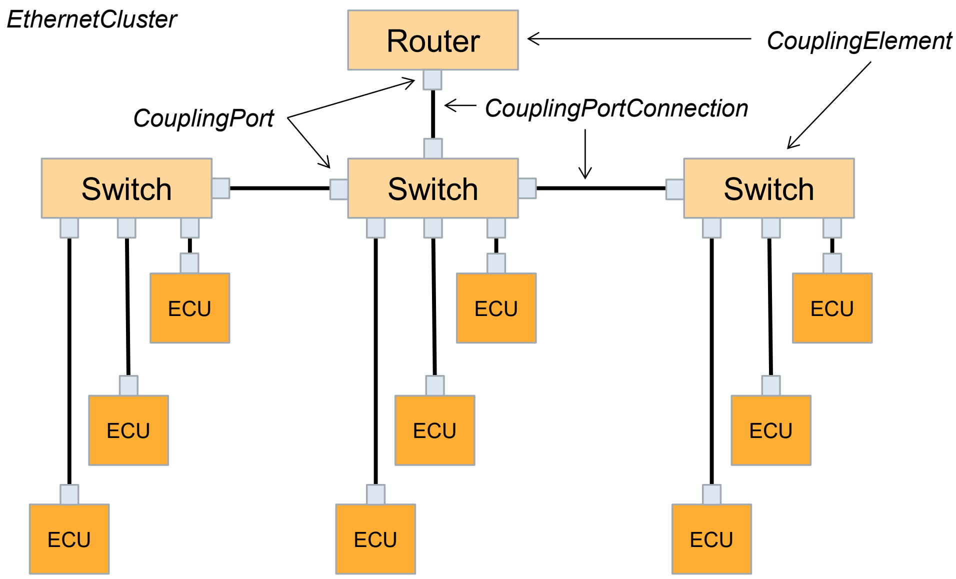

Figure 3.9: Example of an EthernetCluster

Figure 3.9 illustrates an example of an EthernetCluster. In this figure the focus is on the *Link Layer* and represents the wiring of ECUs, their communication connectors, switches, hubs, routers, and how these elements are connected electrically.

To describe the Ethernet at the data link- and physical layer the following System Template meta-model classes are used: EthernetCluster, EthernetCommunicationController, EthernetCommunicationConnector, EthernetPhysicalChannel, CouplingElement, CouplingPort and CouplingPortConnection (see Figure 3.10).

AUTOSAR supports the wake-up and sleep mechanism complying with the Open Alliance TC10 specification (OA TC10, see [14]), which is used for a switched Ethernet network. The details are described in chapter 3.3.6.8.

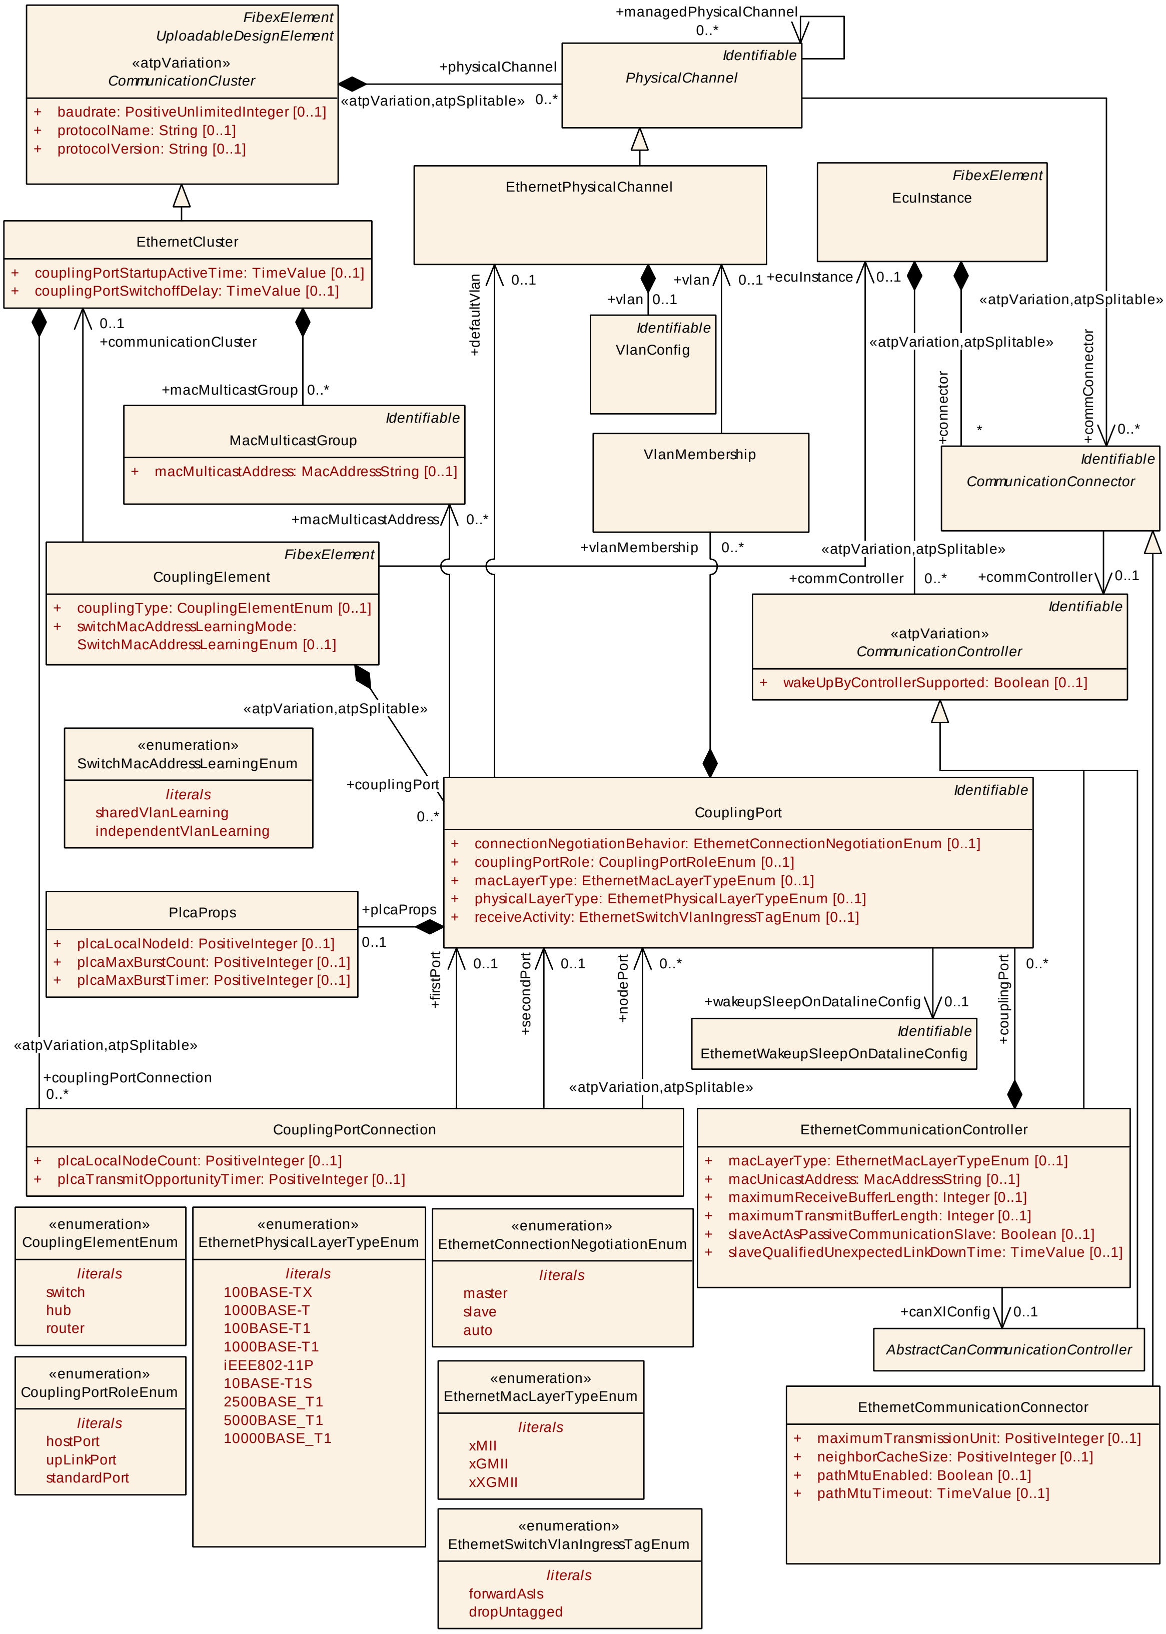

Figure 3.10: Ethernet topology elements (Fibex4Ethernet_Topology)

[constr_5251] CouplingPort.connectionNegotiationBehavior shall exist

Imposition time: IT_SysDesc

⌈The attribute CouplingPort.connectionNegotiationBehavior shall be defined.⌋

3.3.6.1 Ethernet Cluster

Each EthernetCluster may have globally defined MacMulticastGroups. MacMulticastGroups have a macMulticastAddress (for example 01:00:5E:7F:FF:FF). One sender can handle many receivers simultaneously, if the receivers have all the same macMulticastAddress.

[constr_3047] Uniqueness of macMulticastAddresses

Imposition time: IT_SysDesc

⌈A macMulticastAddress shall be unique in a particular EthernetCluster.⌋

[constr_5453] Existence of macMulticastAddress

Imposition time: IT_SysDesc

⌈For each MacMulticastGroup, the attribute macMulticastAddress shall exist.⌋

For details on CouplingPort specific attributes of EthernetCluster in relation with Partial Networks please refer to chapter 5.4.1.1.

Class	«atpVariation» **EthernetCluster**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Ethernet-specific cluster attributes. **Tags:** atp.recommendedPackage=CommunicationClusters

Aggregated by	EthernetCluster.macMulticastGroup			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
macMulticast Address	MacAddressString	0..1	attr	A multicast MAC address (Media Access Control address) is a identifier for a group of hosts in a network.

Table 3.48: MacMulticastGroup

[TPS_SYST_02362] Relevance of attribute `EthernetCluster.baudrate` ⌈The value of the attribute `baudrate` in the context of an `EthernetCluster` has no meaning and shall be ignored.⌋

The communication speed is defined by the attribute `CouplingPort.physicalLayerType` of the involved `CouplingPort`s.

3.3.6.2 Ethernet Physical Channel

The `EthernetPhysicalChannel` represents a VLAN. VLANs (IEEE 802.1q) divide physical Ethernet networks in logical subnets. Their realization requires switches with VLAN support. VLANs are defined on a switch on a port-by-port basis.

The term `EthernetPhysicalChannel` may be misleading because it actually does *not* defined the physical (electrical) attributes of the communication but the `EthernetPhysicalChannel` defines the VLANs as *logical* broadcast domains in which the communication partners can interact.

Regardless whether the Ethernet communication uses tagged [TPS_SYST_01095] or untagged [TPS_SYST_01096] VLANs all communication needs to be defined within respective `EthernetPhysicalChannel`s as defined in chapter 6.1.

[TPS_SYST_01095] tagged VLANs

Upstream requirements: RS_SYST_00039

⌈In the System Description a VLAN is represented by an EthernetPhysicalChannel and is identified by its vlanIdentifier.⌋

[TPS_SYST_01096] untagged VLANs

Upstream requirements: RS_SYST_00039

⌈If the VlanConfig and the vlanIdentifier are not defined for an EthernetPhysicalChannel than the channel is called "untagged".⌋

Every Frame that is sent over a "tagged" VLAN is tagged with a VLAN Tag. With this tag every receiving switch has the information about the VLAN that the Frame belongs to. The VLAN Tag that is attached to a Frame contains the user priority for the Frame that is described with the defaultPriority and the vlanIdentifier.

Class	**EthernetPhysicalChannel**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	The EthernetPhysicalChannel represents a VLAN or an untagged channel. An untagged channel is modeled as an EthernetPhysicalChannel without an aggregated VLAN.

[constr_5454] Existence of vlanIdentifier

Imposition time: IT_SysDesc

⌈For each VlanConfig, the attribute vlanIdentifier shall exist.⌋

3.3.6.2.1 VLAN Priority

The Priority is a 3-bit field which refers to the IEEE 802.1Q priority. It indicates the frame priority level. Values are from 0 (best effort) to 7 (highest); 1 represents the lowest priority. These values can be used to prioritize different classes of traffic (voice, video, data, etc.). The priority is contained in the Ethernet Header together with the vlanIdentifier.

The defaultPriority can be overwritten on different levels:

1. NetworkEndpoint
2. ApplicationEndpoint
3. ProvidedServiceInstance or ConsumedEventGroup

If a priority on an ApplicationEndpoint is defined the priorities in the Network-Endpoint and the defaultPriority in the VlanMembership would be ignored.

The following table shows two CouplingPorts. Both have two NetworkEndpoints and for each NetworkEndpoint two ApplicationEndpoints are defined. This means that per Port two IP Addresses and four Tcp-Ports are used. On each level a priority may be defined.

For NEP1.1 no priority is defined. This means that the Default-Priority from Coupling-Port1 is valid. On CouplingPort1 all messages have the Priority 0 ("‘best effort"’) except for messages that are going over ApplicationEndpoint AEP1.1.2 and AEP 1.2.2. These messages have the priority 1 (higher priority). On CouplingPort2 the priority is overwritten on several levels. Please note that AEP 2.2.1 and AEP 2.2.2 are reducing the priority that is defined on the NEP2.2.

<table>
<tr><th>Port (Default Priority)</th><th>NetworkEndpoint (e.g. IP Address)</th><th>ApplicationEndpoint (e.g. Tcp Port)</th></tr>
<tr><td rowspan="4">CouplingPort1: Prio. 0</td><td rowspan="2">NEP1.1: Prio. —</td><td>AEP 1.1.1: Prio. —</td></tr>
<tr><td>AEP 1.1.2: Prio. 1</td></tr>

		AEP 2.2.2: Prio. 0

Table 3.51: VLAN Priority Example

3.3.6.3 Ethernet Coupling Elements and Coupling Ports

A `CouplingElement` is used to connect `EcuInstance`s via `CouplingPort`s to `EthernetPhysicalChannel`s (VLANs) that are defined within an `EthernetCluster`.

`CouplingElement`s can reach from a simple hub to a complex managed switch or even devices with functionalities in higher layers. A `CouplingElement` references the `EthernetCluster` and contains a collection of available `CouplingPort`s. The `couplingType` identifies the `CouplingElement` as a switch, hub or router.

Class	**CouplingElement**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	A CouplingElement is used to connect EcuInstances to the VLAN of an EthernetCluster. Coupling Elements can reach from a simple hub to a complex managed switch or even devices with functionalities in higher layers. A CouplingElement that is not related to an EcuInstance occurs as a dedicated single device. **Tags:** atp.recommendedPackage=CouplingElements

couplingPort	CouplingPort	*	aggr	Hardware Port of the CouplingElement that is used to connect this CouplingPort to EcuInstances or other CouplingElements. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=couplingPort.shortName, coupling Port.variationPoint.shortLabel vh.latestBindingTime=postBuild
couplingType	CouplingElementEnum	0..1	attr	Describes the coupling type of this CouplingElement.
ecuInstance	EcuInstance	0..1	ref	Optional reference to the ECU where the Coupling Element is located.

▽

△

Class	**CouplingElement**			
firewallRule	StateDependentFirewall	*	ref	Firewall rules defined in the context of a Coupling Element. **Tags:** atp.Status=candidate
switchMac Address LearningMode	SwitchMacAddress LearningEnum	0..1	attr	Defines the MAC address learning mode of the Ethernet switch.

Table 3.52: CouplingElement

Enumeration	**CouplingElementEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology
Note	Identifies the Coupling type.
Aggregated by	CouplingElement.couplingType
Literal	*Description*
hub	A device that is used to connect segments of a LAN. In Hubs frames are "broadcasted" to every one of its ports. **Tags:** atp.EnumerationLiteralIndex=0
router	A device that routes frames between different networks. **Tags:** atp.EnumerationLiteralIndex=1
switch	A device that filters and forwards frames between different LAN segments. **Tags:** atp.EnumerationLiteralIndex=2

Table 3.53: CouplingElementEnum

[constr_5455] Existence of `couplingType`

Imposition time: `IT_SysDesc`

⌈For each `CouplingElement`, the attribute `couplingType` shall exist.⌋

[constr_5456] Existence of `communicationCluster`

Imposition time: `IT_SysDesc`

⌈For each `CouplingElement`, the reference `communicationCluster` shall exist.⌋

[constr_3062] The `EcuInstance` that is referenced from a specific `CouplingElement` shall be connected to the same `EthernetCluster` as the specific `CouplingElement`

Imposition time: `IT_SysDesc`

⌈The `EcuInstance` referenced from a specific `CouplingElement` in the role `ecuInstance` shall be connected via the `CommunicationConnector` and a `EthernetPhysicalChannel` that refers the `CommunicationConnector` to the `EthernetCluster` referenced by the specific `CouplingElement` in the role `communicationCluster`.⌋

Class	**CouplingPort**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	A CouplingPort is used to connect a CouplingElement with an EcuInstance or two CouplingElements with each other via a CouplingPortConnection. Optionally, the CouplingPort may also have a reference to a macMulticastGroup and a defaultVLAN.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	CouplingElement.couplingPort, EthernetCommunicationController.couplingPort			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
connectionNegotiationBehavior	EthernetConnectionNegotiationEnum	0..1	attr	Specifies the connection negotiation of the CouplingPort.
couplingPortDetails	CouplingPortDetails	0..1	aggr	Defines more details of a CouplingPort in case a more specific configuration is required.
couplingPortRole	CouplingPortRoleEnum	0..1	attr	Defines the role this CouplingPort takes in the context of the CouplingElement.
defaultVlan	EthernetPhysicalChannel	0..1	ref	The vLanIdentifier of the referenced VLAN is the Default-PVID (port VLAN ID). A Port VLAN ID is a default VLAN ID that is assigned to an access CouplingPort to designate the VLAN segment to which this port is connected. Also, if a CouplingPort has not been configured with any VLAN memberships, the virtual switch's Port VLAN ID (pvid) becomes the default VLAN ID for the ports connection. This identifier/tag is added for incoming untagged messages at the port (ingress tagging). For outgoing messages with this identifier, the tag is removed at the port (egress untagging, depending on the VlanMembership.sendActivity).
macAddressVlanAssignment	MacAddressVlanMembership	*	aggr	Statically defines the assignment of MAC-Multicast-Addresses, optionally together with VLANs, to this CouplingPort. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=macAddressVlanAssignment.shortName, macAddressVlanAssignment.variationPoint.shortLabel vh.latestBindingTime=postBuild
macLayerType	EthernetMacLayerTypeEnum	0..1	attr	Specifies the mac layer type of the CouplingPort.
macMulticastAddress	MacMulticastGroup	*	ref	Assigns a set of MAC-Multicast-Addresses which are addressable via this CouplingPort. This is a static pre-configuration and further addresses may be learned during runtime. **Tags:** atp.Status=obsolete
macSecProps	MacSecProps	*	aggr	Properties to configure MACsec (Media access control security) and the MKA (MACsec Key Agreement) for the CouplingPort (PHY). **Tags:** atp.Status=candidate
physicalLayerType	EthernetPhysicalLayerTypeEnum	0..1	attr	Specifies the physical layer type of the CouplingPort.
plcaProps	PlcaProps	0..1	aggr	Optional properties for configuration of PLCA (Physical Layer Collision Avoidance) in case 10-BASE-T1S Ethernet is used and PLCA is enabled on the CouplingPort (PHY).
pncMapping	PncMappingIdent	*	ref	Reference to the partial networks this CouplingPort participates in. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=pncMapping

▽

△

Class	**CouplingPort**			
receiveActivity	EthernetSwitchVlan IngressTagEnum	0..1	attr	Defines the handling of frames at the ingress port.
vlan Membership	VlanMembership	*	aggr	Messages of VLANs that are defined here can be communicated via the CouplingPort.
wakeupSleep OnDataline Config	EthernetWakeupSleep OnDatalineConfig	0..1	ref	Optional reference to EthernetWakeupSleepOnDataline Config.

Table 3.54: CouplingPort

Class	CouplingPortConnection			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Connection between two CouplingPorts (firstPort and secondPort) or between a collection of Ports that are all referenced by the portCollection reference.			
Base	*ARObject*			
Aggregated by	EthernetCluster.couplingPortConnection			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
firstPort	CouplingPort	0..1	ref	Reference to the first CouplingPort that is connected via the CouplingPortConnection.

▽

△

Class	**CouplingPortConnection**			
nodePort	CouplingPort	*	ref	Reference to a number of CouplingPorts that are connected via the CouplingPortConnection. This reference shall be used to describe a 10BASE-T1S topology architecture where several CouplingPorts of EthernetCommunicationControllers are connected via one CouplingPortConnection. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=nodePort.couplingPort, nodePort.variationPoint.shortLabel vh.latestBindingTime=postBuild
plcaLocalNodeCount	PositiveInteger	0..1	attr	Defines the number of communication participants in case 10BASE-T1S and the nodePort reference is used.
plcaTransmitOpportunityTimer	PositiveInteger	0..1	attr	Timer for the transmission in bit time to evaluate if a Transmission Opportunity is yield or not.
secondPort	CouplingPort	0..1	ref	Reference to the second CouplingPort that is connected via the CouplingPortConnection.

Table 3.60: CouplingPortConnection

CouplingPorts are hardware ports of CouplingElements and EcuInstances. Connections between CouplingPorts are realized through CouplingPortConnections.

Optionally the CouplingPort of a CouplingElement may also have one or several VlanMemberships, a defaultVlan reference and a reference to a MacMulticastGroup.

[constr_3521] defaultVlan and vlanMembership

Imposition time: IT_SysDesc

⌈If a CouplingPort refers to an EthernetPhysicalChannel in the role defaultVlan the CouplingPort shall also have a vlanMembership defined. This VlanMembership shall point to the same EthernetPhysicalChannel in the role vlan as the defaultVlan.⌋

[constr_3435] Applicability of CouplingPort.macMulticastAddress

Imposition time: IT_SysDesc

⌈The reference CouplingPort.macMulticastAddress is only applicable if the CouplingPort is aggregated by a CouplingElement with couplingType = switch.⌋

[constr_3133] physicalLayerType of connected CouplingPorts

Imposition time: IT_SysDesc

⌈The physicalLayerType of two CouplingPorts which are connected via a CouplingPortConnection shall be equal.⌋

[constr_3134] The connection of two CouplingPorts with connectionNegotiationBehavior set to master is forbidden

Imposition time: IT_SysDesc

⌈The connectionNegotiationBehavior of two CouplingPorts which are connected via a CouplingPortConnection shall not be both set to master.⌋

[constr_3135] The connection of two CouplingPorts with connectionNegotiationBehavior set to slave is forbidden

Imposition time: IT_SysDesc

⌈The connectionNegotiationBehavior of two CouplingPorts which are connected via a CouplingPortConnection shall not be both set to slave.⌋

[TPS_SYST_01097] Assignment of CouplingPorts to a VLAN

Upstream requirements: RS_SYST_00039

⌈CouplingPorts of CouplingElements can be assigned to VLANs (EthernetPhysicalChannels) with the vlanMembership aggregation.⌋

[TPS_SYST_01098] Assignment of CouplingPorts to an "untagged" VLAN

Upstream requirements: RS_SYST_00039

⌈A CouplingPort may be assigned to several VLANs, but only one of those assignments can be "untagged".⌋

[constr_3534] EthernetPhysicalChannel shall only be referenced by one VlanMembership

Imposition time: IT_SysDesc

⌈An EthernetPhysicalChannel shall only be referenced by one VlanMembership in the role VlanMembership.vlan in the scope of one CouplingPort.⌋

Figure 3.11 shows a CouplingElement with two CouplingPorts.

In this example Port 0 is assigned to three VLANs and one "untagged" EthernetPhysicalChannel. VLAN3 is marked as the defaultVlan. With the combination of the defaultVlan and the VlanMembership to the "untagged" EthernetPhysicalChannel the Frames that are transmitted over Port 0 on VLAN3 are "untagged" on the wire in both directions (Tx and Rx). The switch adds the tag for incoming untagged messages at the port (ingress tagging) and for outgoing messages the tag is removed at the port (egress untagging).

Port 1 is assigned to three VLANs. But the VlanMembership to the "untagged" EthernetPhysicalChannel is not defined here. For this reason, Frames that are transmitted over Port 1 on VLAN3 are "tagged".

If a defaultVlan is defined for a CouplingPort but the defaultVlan is not referenced by the VlanMembership then "untagged" Frames can be received via the CouplingPort. But a response can not be send back.

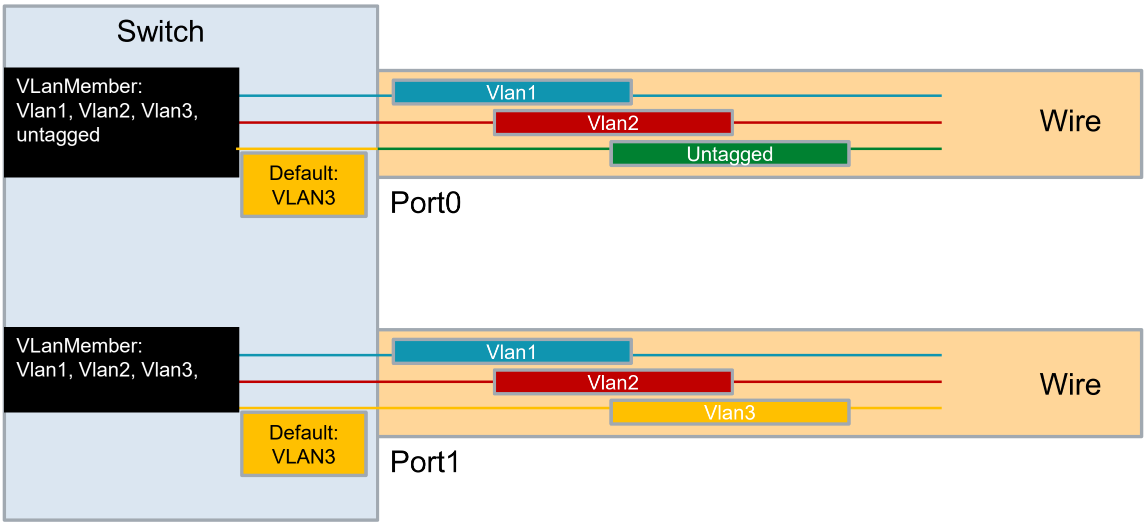

Figure 3.11: Default Vlan Example

3.3.6.4 Ethernet Communication Controller

EthernetCommunicationController is a specialization of the CommunicationController class. It contains the specific Ethernet controller attributes needed for configuring an EcuInstance connected to a certain Ethernet cluster.

Class	«atpVariation» **EthernetCommunicationController**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Ethernet specific communication port attributes.			
Base	*ARObject*, *CommunicationController*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EcuInstance.commController, MachineDesign.communicationController			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
canXlConfig	AbstractCan Communication Controller	0..1	ref	If the Ethernet frames handled by this Ethernet CommunicationController are to be tunneled through CAN XL, then this reference shall refer to the Abstract CanCommunicationController that aggregates the Can ControllerXlConfiguration of the physical CAN XL channel to be used for tunneling.
couplingPort	CouplingPort	*	aggr	Optional CouplingPort that can be used to connect the ECU to a CouplingElement (e.g. a switch).
macLayerType	EthernetMacLayerType Enum	0..1	attr	Specifies the mac layer type of the ethernet controller.
macUnicast Address	MacAddressString	0..1	attr	Media Access Control address (MAC address) that uniquely identifies each EthernetCommunication Controller in the network.

▽

△

Class	«atpVariation» **EthernetCommunicationController**			
maximum ReceiveBuffer Length	Integer	0..1	attr	Determines the maximum receive buffer length (frame length) in bytes.
maximum TransmitBuffer Length	Integer	0..1	attr	Determines the maximum transmit buffer length (frame length) in bytes.
slaveActAs Passive Communication Slave	Boolean	0..1	attr	This attribute specifies if the EcuInstance is acting as a passive communication slave on the connected Physical Channel. This is used for EthernetCommunication Controllers that use Ethernet hardware which supports wake-up and sleep on the network (e.g. Open Alliance TC10 compliant Ethernet hardware).
slaveQualified UnexpectedLink DownTime	TimeValue	0..1	attr	This attribute specifies time when an unexpected link down is evaluated as link down and indicated to the AUTOSAR communication stack.

Table 3.61: EthernetCommunicationController

[constr_3535] EthernetCommunicationController shall aggregate at most one CouplingPort

Imposition time: IT_SysDesc

⌈An EthernetCommunicationController is allowed to aggregate at most one CouplingPort.⌋

[constr_3332] Standardized values for the attribute category of meta-class EthernetCommunicationController

Imposition time: IT_SysDesc

⌈The following values of the attribute category of meta-class EthernetCommunicationController are reserved by the AUTOSAR standard:

- WIRED: This represents the usage of the EthernetCommunicationController in case of a wired ethernet connection
- WIRELESS: This represents the usage of the EthernetCommunicationController in case of a wireless ethernet connection
- CAN_XL: This represents the tunneling of Ethernet frames handled by the EthernetCommunicationController through CAN XL.

⌋

[TPS_SYST_02158] Default value for the attribute category of meta-class EthernetCommunicationController ⌈The default value for the category of an EthernetCommunicationController shall be *WIRED*.⌋

The EthernetCommunicationController has the additional information of a macUnicastAddress. This is a globally unique MAC-address for the CommunicationController.

[constr_3702] Relevant attributes of EthernetCommunicationController for CAN XL

Imposition time: IT_SysDesc

⌈If the category of EthernetCommunicationController is equal to CAN_XL, then only the following attributes of this meta-class are relevant:

- macLayerType
- macUnicastAddress

⌋

[constr_3703] Reference to CanControllerXlConfiguration in case of category CAN_XL

Imposition time: IT_SysDesc

⌈If the category of EthernetCommunicationController is equal to CAN_XL, then the reference canXlConfig of EthernetCommunicationController shall refer to the CanCommunicationController aggregating the CanControllerConfiguration which in turn aggregates the CanControllerXlConfiguration that is used for tunneling of the Ethernet frames associated with the aforementioned EthernetCommunicationController.⌋

3.3.6.5 Ethernet Communication Connector

EthernetCommunicationConnector adds the Ethernet specific attributes to the CommunicationConnector.

Class	**EthernetCommunicationConnector**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Ethernet specific attributes to the CommunicationConnector.			
Base	*ARObject*, *CommunicationConnector*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EcuInstance.connector, MachineDesign.communicationConnector			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
ethIpProps	EthIpProps	0..1	ref	EcuInstance specific IP attributes.
maximum Transmission Unit	PositiveInteger	0..1	attr	This attribute specifies the maximum transmission unit in bytes.
neighborCache Size	PositiveInteger	0..1	attr	This attribute specifies the size of neighbor cache or ARP table in units of entries.

▽

△

Class	**EthernetCommunicationConnector**			
pathMtu Enabled	Boolean	0..1	attr	If enabled the IPv4/IPv6 processes incoming ICMP "Packet Too Big" messages and stores a MTU value for each destination address.
pathMtuTimeout	TimeValue	0..1	attr	If this value is >0 the IPv4/IPv6 will reset the MTU value stored for each destination after n seconds.

Table 3.62: EthernetCommunicationConnector

[constr_3331] Standardized values for the attribute category of meta-class EthernetCommunicationConnector

Imposition time: IT_SysDesc

⌈The following values of the attribute category of meta-class EthernetCommunicationConnector are reserved by the AUTOSAR standard:

- WIRED: This represents the usage of the EthernetCommunicationConnector in case of a wired ethernet connection
- WIRELESS: This represents the usage of the EthernetCommunicationConnector in case of a wireless ethernet connection

⌋

[TPS_SYST_02157] Default value for the attribute category of meta-class EthernetCommunicationConnector ⌈The default value for the category of an EthernetCommunicationConnector shall be *WIRED*.⌋

[constr_3335] Allowed references between EthernetCommunicationConnector and EthernetCommunicationController

Imposition time: IT_SysDesc

⌈An EthernetCommunicationConnector is only allowed to reference an EthernetCommunicationController in the role commController that has the same category value as the referencing EthernetCommunicationConnector.⌋

3.3.6.6 Ethernet Switch Driver

Ethernet networks in an automotive environment consist basically of ECUs with a single port PHY and switch ECUs with several ports. Different to consumer networks, where switches are typically stand-alone devices, switches in automotive networks may be integrated and connected to a CPU via MII and other interfaces. The configuration of these switches does influence the communication behavior within the network.

3.3.6.6.1 Ethernet switch port structure

In order to describe switched Ethernet networks it is essential to describe some parts of an Ethernet switch. Examples are scheduling and forwarding mechanisms within a switch as well as the switch structure within its ports.

As shown in figure 3.12, the switch consists of a certain number of ports. Each port has its own set of egress FIFOs in which the incoming packets are buffered. How the messages in the FIFOs will be forwarded depends mainly on the shaping and port scheduling mechanisms. Thus, the parametrization of the egress port influences the latency of messages within the network.

Please note that the egress port structures in figure 3.12 are meant as an example. Other structures with different FIFO numbers are possible as well.

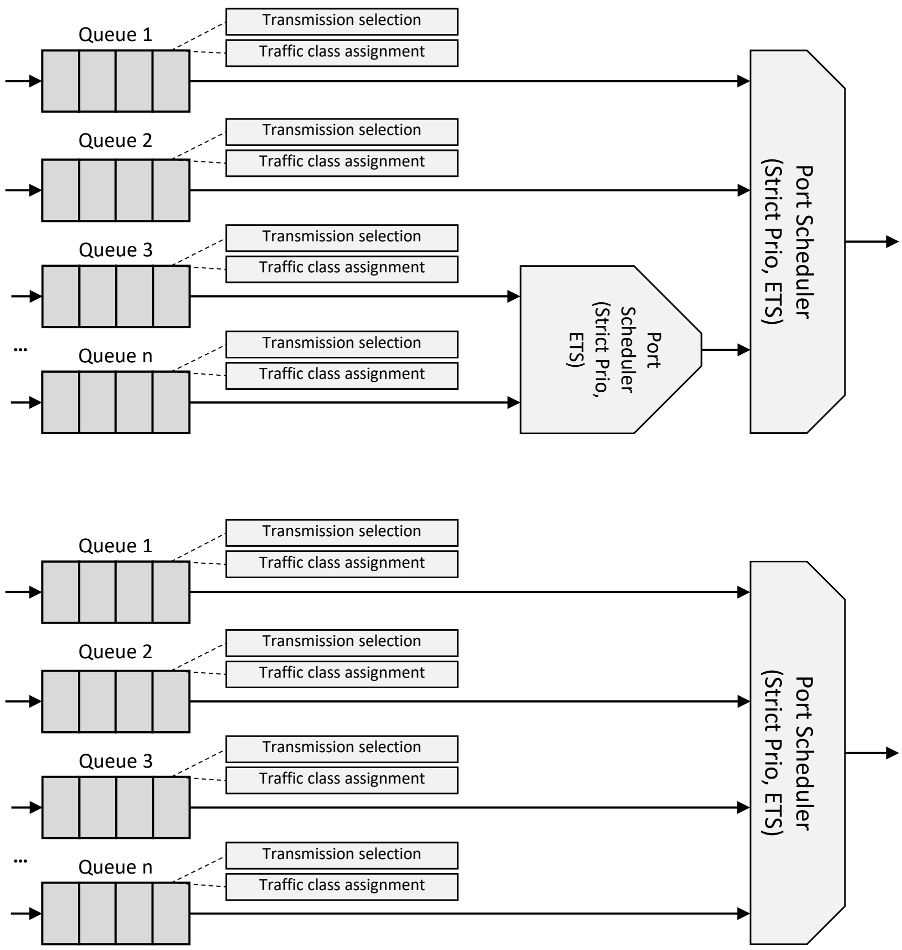

Figure 3.12: Example egress switch port configurations

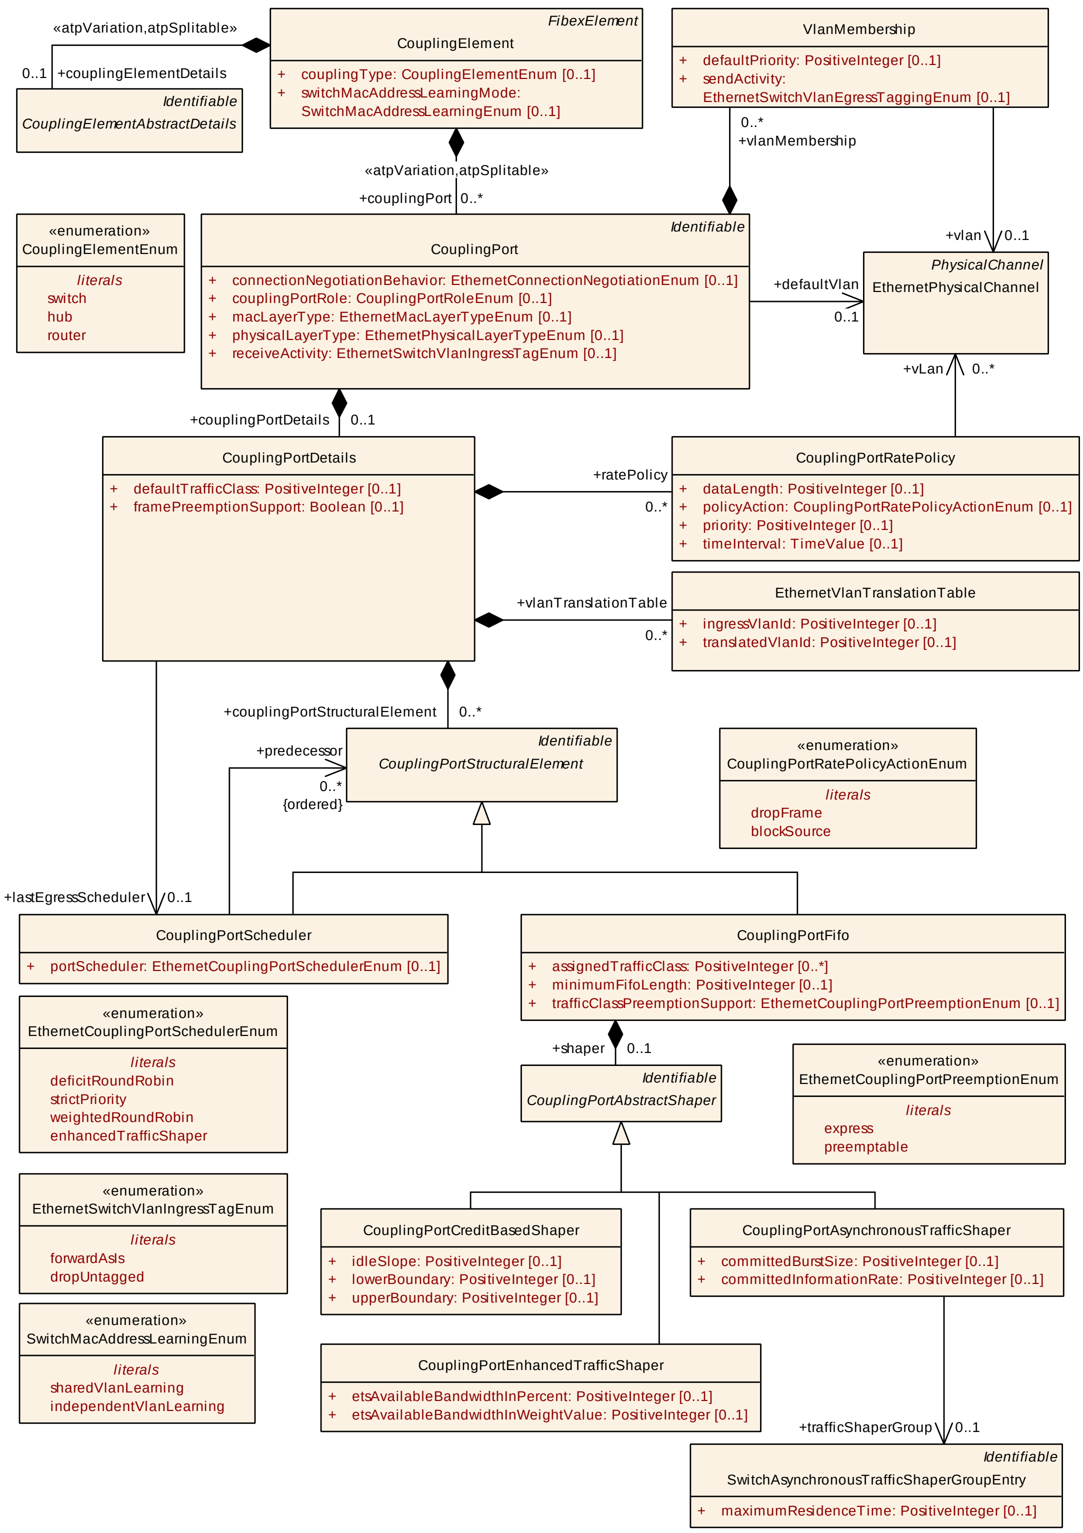

Figure 3.13: Egress switch port structure

The structural description of an Ethernet switch is based on the already existing `CouplingElement` in the System Template. Each `CouplingElement` can already have a set of `CouplingPort`s.

In case a detailed Switch configuration is required, there is the configuration option to add to the CouplingPort a CouplingPortDetails element which encapsulates the structural description of one switch port.

The elements which one switch port consists of are (egress side):

- CouplingPortFifo
- CouplingPortScheduler.

The model allows to collect the egress parts of one switch port in the CouplingPortDetails.couplingPortStructuralElements.

[TPS_SYST_03006] Ethernet switch egress port setup

Upstream requirements: RS_SYST_00052

⌈Two setups can be defined at an egress port of a switch:

- The switch port has only one Fifo:
  - the CouplingPortFifo element is aggregated at the CouplingPortDetails.couplingPortStructuralElements
  - no CouplingPortDetails.lastEgressScheduler is defined.
- The switch port has at least one scheduler
  - the various switch port elements are all aggregated at the CouplingPortDetails.couplingPortStructuralElements
  - the CouplingPortScheduler which is the last scheduler in a chain of structural elements is additionally referenced in the role CouplingPortDetails.lastEgressScheduler

⌋

The modeling approach is based on a predecessor chain model where the chain is started by the last scheduler in the switch port and defines where the input to this scheduler comes from. The input to a scheduler can come from several predecessor elements which might be

- another CouplingPortScheduler
- a CouplingPortFifo.

Frame preemption is a features specified in IEEE Std 802.1Q-2022 [15] standard. Also for CouplingPorts used in the context of an Ethernet switch the specification of [TPS_SYST_03127] and [constr_3782] applies.

Additionally a CouplingPortFifo (i.e. queue) has the possibility to define whether frame preemption is enabled for that specific CouplingPortFifo using the attribute

CouplingPortFifo.trafficClassPreemptionSupport. Since the CouplingPortFifo is associated with exactly one traffic class as defined by assignedTrafficClass, the trafficClassPreemptionSupport is implicitly associated with exactly one traffic class as well.

[constr_3783] Definition of CouplingPortFifo.trafficClassPreemptionSupport only in context of an Ethernet switch

Imposition time: IT_SysDesc

⌈If a CouplingPort is aggregated by a CouplingElement with CouplingElement.couplingType equal to CouplingElementEnum.switch and CouplingPort.couplingPortDetails.framePreemptionSupport is set to true, then the attribute CouplingPortFifo.trafficClassPreemptionSupport shall be defined.⌋

[TPS_SYST_03128] Traffic class specific enabling of egress frame preemption
⌈The attribute CouplingPortFifo.trafficClassPreemptionSupport defines whether frames handled by this CouplingPortFifo shall be

- EthernetCouplingPortPreemptionEnum.preemptable or have the setting
- EthernetCouplingPortPreemptionEnum.express, which makes then non preemptable

according to IEEE Std 802.1Q-2022 [15].⌋

Table 3.75: CouplingPortRatePolicyActionEnum

3.3.6.6.3 Ethernet packet forwarding

Besides the modeling of egress ports, it is necessary to specify how incoming packets are forwarded to the egress ports. For this purpose, different assignment policies of packets to egress port FIFOs are implemented in switches.

As an example, the Ethernet priority field can be evaluated and remapped into an regenerated priority: Within the VLAN-tag, the PCP-field (priority code point) is a parameter which can be modified at an ingress port of an Ethernet switch. For this purpose a priority regeneration table can be defined.

The CouplingPortDetails.ethernetPriorityRegeneration is optional in case the feature of priority regeneration is not be used.

[TPS_SYST_03003] Ethernet priority regeneration

Upstream requirements: RS_SYST_00052

⌈The CouplingPortDetails.ethernetPriorityRegeneration specifies which ingressPriority is mapped to which regeneratedPriority.⌋

[constr_3515] Fully filled EthernetPriorityRegeneration table

Imposition time: IT_SysDesc

⌈In case the CouplingPortDetails.ethernetPriorityRegeneration is defined it shall contain exactly 8 elements of EthernetPriorityRegeneration, one for each value of ingressPriority (0-7).⌋

The (potentially remapped) Ethernet priority field can be evaluated and mapped to a traffic class. Such a traffic class is again mapped to an egress FIFO. Other header information of the Ethernet frame can be also used for the assignment of Ethernet frames to egress FIFOs. For the mapping to a certain traffic class, the following tables are necessary.

PORT-based Mapping	*Traffic Class*
Port2, Port3, Port4	7
Port1	6
–	5
–	4
–	3
–	2
–	1
–	0

Table 3.76: Port to Traffic Class mapping

Prio 1	6
Prio 2-7	5
–	4
–	3
–	2

▽

△

PCP-based Mapping	Traffic Class
–	1
–	0

Table 3.77: PCP-field to Traffic Class mapping

While the first table shows the mapping of ingress-ports to traffic classes, the second table shows the priority-based mapping which can be defined per ingress port. Both tables are in conflict with each other, i.e. it has to be decided which mapping is applied.

Also the mapping of a traffic class to a FIFO shall be done on a per port basis. An example is shown in the following table.

Traffic Class	FIFO (if 4 FIFOs available)
7	3
6	2
0-5	1
–	0

Table 3.78: Traffic Class to FIFO mapping

[TPS_SYST_03010] Ethernet switch packet to traffic class assignment

Upstream requirements: RS_SYST_00052

⌈The aggregation ethernetTrafficClassAssignment defines a PCP-field (priority) to traffic class mapping. A set of prioritys is mapped to one trafficClass.⌋

The priority based mapping of [TPS_SYST_03010] does not have to be complete. There may not be a CouplingPortTrafficClassAssignment defined for a set of priorities, or there may not even be any CouplingPortTrafficClassAssignment defined. For the case that a CouplingPortTrafficClassAssignment for a dedicated priority is not given by any CouplingPortTrafficClassAssignment at a CouplingPortDetails, the defaultTrafficClass takes effect as defined in [TPS_SYST_03129].

[constr_5464] Existence of trafficClass

Imposition time: IT_SysDesc

⌈For each CouplingPortTrafficClassAssignment, the attribute trafficClass shall exist.⌋

3.3.6.6.4 Ethernet VLAN Configuration

For each VLAN identifier a table is necessary which stores at which egress port the corresponding VLAN is tagged or untagged. For an 8-port switch, this table could look like the following example where T stands for tagging and U for untagging:

	Port number							
VLAN-ID	1	2	3	4	5	6	7	8
1	T	T	–	U	–	–	–	T
2	T	U	–	T	–	–	–	T
...								
4094								

Table 3.81: VLAN Forwarding table

Incoming packets which contain a VLAN-ID of e.g. 1 can be forwarded to the ports 1, 2, 4, and 8. At ports 1, 2, and 8 these packets will be transmitted with the VLAN tag and at port 4 the tag will be removed. If a broadcast message with e.g. VLAN-ID 2 will be received at port 2 it will be forwarded to port 1, 4, and 8. The other ports 3, 5, 6, and 7 are not in the same VLAN. Thus, the packet will not be forwarded to these egress ports. The table considers only messages which contain a VLAN-ID within the switch.

CouplingPort.vlanMembership defines specific attributes to the behavior a packet with a specific VLAN-ID shall have on this CouplingPort.

[TPS_SYST_03004] VLAN specific sending behavior

Upstream requirements: RS_SYST_00052

⌈The VlanMembership.sendActivity defines for a CouplingPort and VLAN the sending behavior:

- sentTagged: packet is sent at this CouplingPort with the defined VLAN-ID
- sentUntagged: packet is sent at this CouplingPort but the VLAN-ID is removed before sending
- notSent: packet is not sent at this CouplingPort

⌋

Another table specifies a port-based modification of the VLAN-ID or an insertion of the VLAN-ID into the Ethernet message:

Port number	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*
VLAN-Id	2	–	–	6	–	–	–	–

Table 3.82: Ingress VLAN Modification/Insertion Table

In this example, all incoming messages at port one will get the VLAN-Id 2 no matter whether they already had one before. At port 4, all incoming messages will get a 6 as their VLAN-Id. At the remaining ports, no VLAN-Ids will be inserted and an existing VLAN-Id in the Ethernet-message will remain without modification.

Note	Defines the MAC address learning mode.
Aggregated by	CouplingElement.switchMacAddressLearningMode
Literal	***Description***
independentVlan Learning	Defines the Independent Vlan Learning (IVL) mode. **Tags:** atp.EnumerationLiteralIndex=1
sharedVlan Learning	Defines the Shared Vlan Learning (SVL) mode. **Tags:** atp.EnumerationLiteralIndex=0

Table 3.84: SwitchMacAddressLearningEnum

In order to pre-configure MAC multicast addresses associated with an Ethernet switch port configuration the `CouplingPort.macAddressVlanAssignment` is used. This assignment references one or more `MacMulticastGroup`s in the role `MacAddressVlanMembership.macMulticastAddress`. (Note that in previous AUTOSAR releases the reference `CouplingPort.macMulticastAddress` was used for this purpose, however that outdated approach does not support the additional definition of an VLAN relation).

Additionally, if CouplingElement.switchMacAddressLearningMode = SwitchMacAddressLearningEnum.independentVlanLearning is defined, then the MacAddressVlanMembership is also able to reference one or more EthernetPhysicalChannels in the role MacAddressVlanMembership.vlan, stating that the referenced MacAddressVlanMembership.macMulticastAddress are to be considered in the referenced MacAddressVlanMembership.vlan only.

Class	**MacAddressVlanMembership**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Assigns a set of MAC-Multicast-Addresses which are addressable via the CouplingPort aggregating this MacAddressVlanMembership. Optionally also assigns a set of VLANs to this relation. This is a static pre-configuration and further addresses may be learned during runtime.

Aggregated by	CouplingPort.macAddressVlanAssignment			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
macMulticastAddress	MacMulticastGroup	*	ref	Defines a set of macMulticastAddresses to be mapped to the CouplingPort.
vlan	EthernetPhysicalChannel	*	ref	Defines a set of VLANs the set of macMulticastAddress apply to.

Table 3.85: MacAddressVlanMembership

[TPS_SYST_03120] Definition of MAC multicast addresses in case of SwitchMacAddressLearningEnum.sharedVlanLearning

Upstream requirements: RS_SYST_00052

⌈If a CouplingPort is owned by a CouplingElement with switchMacAddressLearningMode = sharedVlanLearning (or switchMacAddressLearningMode not defined), then the CouplingPort.macAddressVlanAssignment defines a set of MacMulticastGroups which shall be pre-configured at that CouplingPort.⌋

[TPS_SYST_03121] Definition of MAC multicast addresses in combination with VLANs in case of SwitchMacAddressLearningEnum.independentVlanLearning

Upstream requirements: RS_SYST_00052

⌈If a CouplingPort is owned by a CouplingElement with switchMacAddressLearningMode = independentVlanLearning, then the CouplingPort.macAddressVlanAssignment defines a set of MacMulticastGroups and EthernetPhysicalChannels (representing VLANs) which shall be pre-configured at that CouplingPort.⌋

[constr_3764] Applicability of CouplingPort.macAddressVlanAssignment

Imposition time: IT_SysDesc

⌈The aggregation CouplingPort.macAddressVlanAssignment shall only exist if the CouplingPort is aggregated by a CouplingElement with couplingType = CouplingElementEnum.switch.⌋

[constr_3765] Applicability of MacAddressVlanMembership.vlan

Imposition time: IT_SysDesc

⌈The reference MacAddressVlanMembership.vlan shall only exist if the CouplingPort aggregating this MacAddressVlanMembership is aggregated by a CouplingElement with switchMacAddressLearningMode = SwitchMacAddressLearningEnum.independentVlanLearning.⌋

[constr_3766] Valid MacAddressVlanMembership.vlan target EthernetPhysicalChannel

Imposition time: IT_SysDesc

⌈If an EthernetPhysicalChannel is referenced by a CouplingPort.macAddressVlanAssignment.vlan, then that EthernetPhysicalChannel shall also be referenced by the same CouplingPort via CouplingPort.vlanMembership.vlan⌋

3.3.6.6.5 Semi-static DHCP server configuration

The ECU which manages the Ethernet switch may run a semi-static DHCP server.

[TPS_SYST_03013] Semi-static DHCP server configuration

Upstream requirements: RS_SYST_00052

⌈In order to be able to assign always the same IP-address to a dedicated DHCP client, the DHCP server needs the information at which switch port the DHCP request with the specific MAC address has been received. With this switch port information the DHCP server will assign the IP-address according to the VlanMembership.dhcpAddressAssignment.

This allows the assignment of MAC addresses by the Tier 1 and assignment of IP addresses by the OEM. With this mechanism it is also possible to assign different IP addresses to several VLANs at the same port.⌋

3.3.6.6.6 Stream Identification and per-stream filtering and policing

A stream identification and per-stream filtering and policing may be configured to be performed by a switch. For this purpose the `CouplingElement` may aggregate a `CouplingElement.couplingElementDetails`.

Note: the term "stream" is used in this chapter according to the definition in IEEE Std 802.1Q-2022 [15]. It is equivalent to the term "frame" (i.e. Ethernet frame).

The specialization for switch details is defined using CouplingElementSwitchDetails.

[constr_3762] Usage of CouplingElementSwitchDetails only on an Ethernet switch

Status: DRAFT
Imposition time: IT_SysDesc

Table 3.90: CouplingElementSwitchDetails

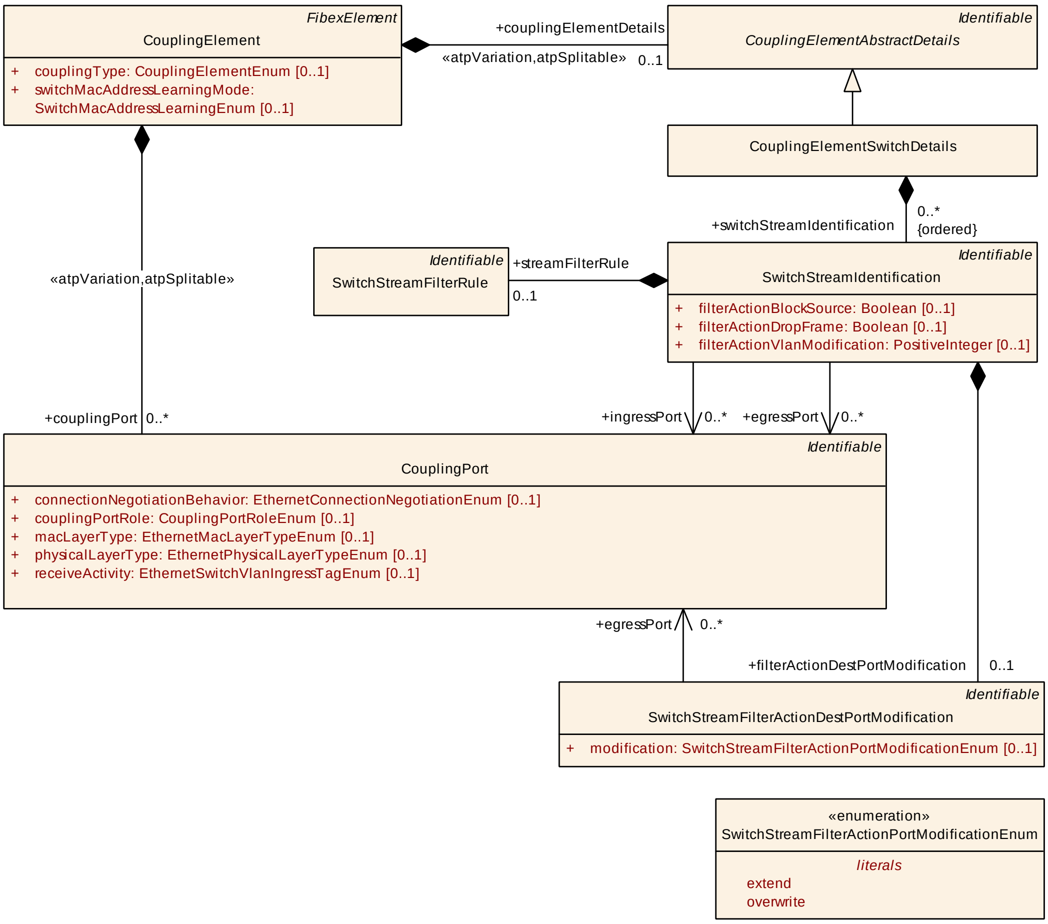

Figure 3.18: Ethernet SwitchStreamIdentification

The list of CouplingElementSwitchDetails.switchStreamIdentification elements is ordered, thus it is essential in which order the SwitchStreamIdentification entries are defined. The earlier entries in the list are matched before later entries in the list. Thus, if a frame would match several SwitchStreamIdentification entries, only the first match from the list is getting effective. Later matches are not considered.

The SwitchStreamIdentification applies to streams in the Ethernet switch. For the SwitchStreamIdentification one set of criteria is on which CouplingPort a frame has been received and to which CouplingPort(s) this frame will be forwarded to.

[TPS_SYST_03112] ingressPort definition for SwitchStreamIdentification

Status: DRAFT

Upstream requirements: RS_SYST_00052, RS_SYST_00064

⌈If a SwitchStreamIdentification references one or more CouplingPorts in the role ingressPort, then a frame is considered matching for this ingress check if that frame is received over any of the referenced CouplingPorts in the role ingressPort.

If a SwitchStreamIdentification references no CouplingPorts in the role ingressPort, then a frame is considered matching for this ingress check regardless over which CouplingPort that frame has been received.⌋

[TPS_SYST_03113] egressPort definition for SwitchStreamIdentification
Status: DRAFT
Upstream requirements: RS_SYST_00052, RS_SYST_00064

⌈If a SwitchStreamIdentification references one or more CouplingPorts in the role egressPort, then a frame is considered matching for this egress check if that frame is forwarded to all of the referenced CouplingPorts in the role egressPort.

If a SwitchStreamIdentification references no CouplingPorts in the role egressPort, then a frame is considered matching for this egress check regardless to which CouplingPorts that frame is forwarded.⌋

For further behavioral aspects refer to the SWS Switch Driver document [16].

overwrite	Overwrite the egress destination of an Ethernet frame. **Tags:** atp.EnumerationLiteralIndex=1 atp.Status=candidate

Table 3.101: SwitchStreamFilterActionPortModificationEnum

After the stream actions of [TPS_SYST_03113] have been performed it is possible to define a SwitchStreamFilterEntry which becomes active when a frame matches one of the referenced SwitchStreamIdentifications in the role SwitchStreamFilterEntry.streamIdentificationHandle.

The list of CouplingElementSwitchDetails.streamFilter elements is ordered, thus it is essential in which order the SwitchStreamFilterEntry entries are defined. The earlier entries in the list are matched before later entries in the list. Thus, if a SwitchStreamIdentification is referenced by several SwitchStreamFilterEntry elements in the role streamIdentificationHandle, then only the first match from the list is getting effective. Later matches are not considered.

[TPS_SYST_03115] SwitchStreamFilterEntry for SwitchStreamIdentification

Status: DRAFT

Upstream requirements: RS_SYST_00052, RS_SYST_00064

⌈If a SwitchStreamFilterEntry refers to a SwitchStreamIdentification in the role streamIdentificationHandle, then this SwitchStreamFilterEntry is executed when a frame matches the SwitchStreamIdentification.

If a SwitchStreamFilterEntry has the attribute streamIdentificationWildcard set to *true*, then any SwitchStreamIdentification will be matching this SwitchStreamFilterEntry.⌋

Further actions defined in the context of the SwitchStreamFilterEntry are:

- assigning an asynchronousTrafficShaper
- assigning a streamGate
- assigning a flowMetering

3.3.6.7 TcpIp stack configuration properties

The EcuInstance references the following elements and allows to set Ecu specific TcpIp stack configuration options in the System Description:

- EthIpProps - used to configure IPv4 and IPv6
- EthTcpIpProps - used to configure TCP and UDP
- EthTcpIpIcmpProps - used to configure ICMP

3.3.6.7.1 IP configuration properties

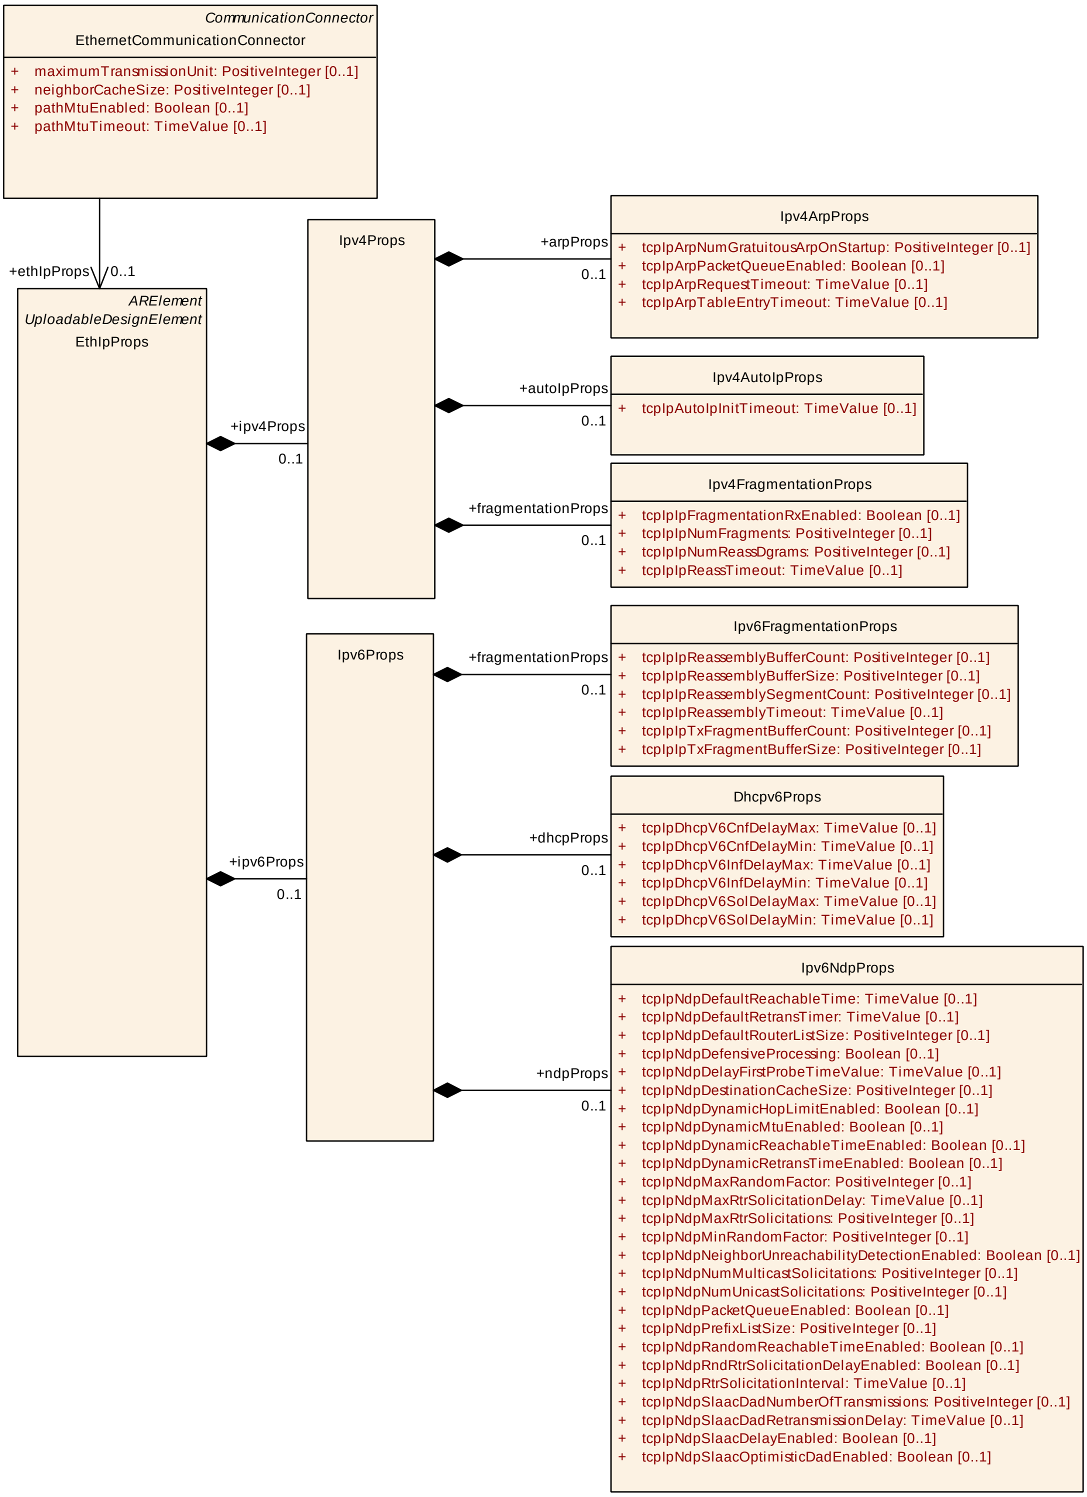

Figure 3.21: Ecu specific IP configuration options

Class	EthIpProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class is used to configure the EcuInstance specific IP attributes. **Tags:** atp.recommendedPackage=EthIpProps			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
ipv4Props	Ipv4Props	0..1	aggr	Configuration options for IPv4.
ipv6Props	Ipv6Props	0..1	aggr	Configuration options for IPv6.

Table 3.107: EthIpProps

Class	Ipv4Props			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class specifies the configuration options for IPv4.			
Base	*ARObject*			
Aggregated by	EthIpProps.ipv4Props			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
arpProps	Ipv4ArpProps	0..1	aggr	Configuration properties for the ARP (Address Resolution Protocol).
autoIpProps	Ipv4AutoIpProps	0..1	aggr	Configuration options for Auto-IP (automatic private IP addressing).
fragmentation Props	Ipv4Fragmentation Props	0..1	aggr	Configuration options for IPv4 packet fragmentation/ reassembly.

Table 3.108: Ipv4Props

Class	Ipv4ArpProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Specifies the configuration options for the ARP (Address Resolution Protocol).			
Base	*ARObject*			
Aggregated by	Ipv4Props.arpProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
tcpIpArpNum GratuitousArp OnStartup	PositiveInteger	0..1	attr	This attribute specifies the number of gratuitous ARP replies which shall be sent on assignment of a new IP address.
tcpIpArpPacket QueueEnabled	Boolean	0..1	attr	This attribute enables (TRUE) or disables (FALSE) support of the ARP Packet Queue according to IETF RFC 1122, section 2.3.2.2.
tcpIpArp Request Timeout	TimeValue	0..1	attr	This attribute specifies a timeout in seconds for the validity of ARP requests. After the transmission of an ARP request the TcpIp shall skip the transmission of any further ARP requests to the same destination within a duration of tcpIpArpRequestTimeout seconds. (IETF RFC 1122, section 2.3.2.1).
tcpIpArpTable EntryTimeout	TimeValue	0..1	attr	This attribute specifies the timeout in seconds after which an unused ARP entry is removed.

Table 3.109: Ipv4ArpProps

[constr_5126] Value range of Ipv4ArpProps.tcpIpArpNumGratuitousArpOnStartup

Imposition time: IT_SysDesc

⌈If defined, the value of Ipv4ArpProps.tcpIpArpNumGratuitousArpOnStartup shall be in the range of 0..255.⌋

Class	Ipv4AutoIpProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Specifies the configuration options for Auto-IP (automatic private IP addressing).			
Base	*ARObject*			
Aggregated by	Ipv4Props.autoIpProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
tcpIpAutoIpInit Timeout	TimeValue	0..1	attr	This attribute specifies the time in seconds Auto-IP waits at startup, before beginning with ARP probing. This delay is used to give DHCP time to acquire a lease in case a DHCP server is present.

Table 3.110: Ipv4AutoIpProps

Class	Ipv4FragmentationProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	Specifies the configuration options for IPv4 packet fragmentation/reassembly.			
Base	*ARObject*			
Aggregated by	Ipv4Props.fragmentationProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
tcpIpIp Fragmentation RxEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support for reassembling of incoming datagrams that are fragmented according to IETF RFC 815 (IP Datagram Reassembly Algorithms).
tcpIpIpNum Fragments	PositiveInteger	0..1	attr	Specifies the maximum number of IP fragments per datagram.
tcpIpIpNum ReassDgrams	PositiveInteger	0..1	attr	Specifies the maximum number of fragmented IP datagrams that can be reassembled in parallel.
tcpIpIpReass Timeout	TimeValue	0..1	attr	Specifies the timeout in [s] after which an incomplete datagram gets discarded.

Table 3.111: Ipv4FragmentationProps

[constr_5127] Value range of Ipv4FragmentationProps.tcpIpIpNumFragments

Imposition time: IT_SysDesc

⌈If defined, the value of Ipv4FragmentationProps.tcpIpIpNumFragments shall be in the range of 0..255.⌋

[constr_5128] Value range of Ipv4FragmentationProps.tcpIpIpNumReassDgrams

Imposition time: IT_SysDesc

⌈If defined, the value of Ipv4FragmentationProps.tcpIpIpNumReassDgrams shall be in the range of 0..65535.⌋

Class	**Ipv6Props**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology

Base	*ARObject*			
Aggregated by	EthIpProps.ipv6Props			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
dhcpProps	Dhcpv6Props	0..1	aggr	Configuration properties for DHCPv6.
fragmentationProps	Ipv6FragmentationProps	0..1	aggr	Configuration properties for IPv6 packet fragmentation/reassembly.
ndpProps	Ipv6NdpProps	0..1	aggr	Configuration properties for the Neighbor Discovery Protocol for IPv6.

Table 3.112: Ipv6Props

Class	**Ipv6FragmentationProps**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class specifies the configuration options for IPv6 packet fragmentation/reassembly.			
Base	*ARObject*			
Aggregated by	Ipv6Props.fragmentationProps			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
tcpIpIpReassemblyBufferCount	PositiveInteger	0..1	attr	Number of buffers that can be used for fragment reassembly. In case of a reassembly error or if not all fragments are received in time this buffer will be blocked until the specified "Fragment Reassembly Timeout" has been exceeded. A value of 0 disables fragment reassembly.
tcpIpIpReassemblyBufferSize	PositiveInteger	0..1	attr	Size of each fragment tx buffer in bytes.
tcpIpIpReassemblySegmentCount	PositiveInteger	0..1	attr	Specifies the maximum number of consecutive data segments that can be managed in each reassembly buffer. If all fragments are received in order, only one segment will be needed. To deal with fragments received out of order this value should be configured bigger than 1.
tcpIpIpReassemblyTimeout	TimeValue	0..1	attr	Specifies the timeout in seconds after which an incomplete datagram gets discarded.
tcpIpIpTxFragmentBufferCount	PositiveInteger	0..1	attr	These buffers will be used if the IpV6 receives packets from the upper layer that do not fit into the MTU and thus must be fragmented. A value of 0 disables tx fragmentation.

▽

△

Class	**Ipv6FragmentationProps**			
tcpIpIpTx FragmentBuffer Size	PositiveInteger	0..1	attr	Size of each fragment tx buffer in bytes.

Imposition time: IT_SysDesc

⌈If defined, the value of Dhcpv6Props.tcpIpDhcpV6SolDelayMin and the value of Dhcpv6Props.tcpIpDhcpV6SolDelayMax shall be in the range of 0..100 and the value of Dhcpv6Props.tcpIpDhcpV6SolDelayMax shall be greater than the value of Dhcpv6Props.tcpIpDhcpV6SolDelayMin.⌋

Class	**Ipv6NdpProps**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class specifies the configuration options for the Neighbor Discovery Protocol for IPv6.			
Base	*ARObject*			
Aggregated by	Ipv6Props.ndpProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
tcpIpNdpDefaultReachableTime	TimeValue	0..1	attr	Configuration of the ReachableTime (s) specified in [RFC4861 6.3.2. Host Variables].
tcpIpNdpDefaultRetransTimer	TimeValue	0..1	attr	Configures the default value (s) for the RetransTimer variable specified in [RFC4861 6.3.2. Host Variables].
tcpIpNdpDefaultRouterListSize	PositiveInteger	0..1	attr	Maximum number of default router entries.
tcpIpNdpDefensiveProcessing	Boolean	0..1	attr	If enabled the NDP shall only process Neighbor Advertisements which are received in reaction to a previously transmitted Neighbor Solicitation as well as skipping updates to the Neighbor Cache based on received Neighbor Solicitations. If disabled all Neighbor Advertisements and Solicitations shall be processed as specified in RFC4861.
tcpIpNdpDelayFirstProbeTimeValue	TimeValue	0..1	attr	Delay before sending the first NUD probe in (s).
tcpIpNdpDestinationCacheSize	PositiveInteger	0..1	attr	Maximum number of entries in the destination cache.
tcpIpNdpDynamicHopLimitEnabled	Boolean	0..1	attr	If enabled the default hop limit may be reconfigured based on received Router Advertisements.
tcpIpNdpDynamicMtuEnabled	Boolean	0..1	attr	Allow dynamic reconfiguration of link MTU via Router Advertisements.
tcpIpNdpDynamicReachableTimeEnabled	Boolean	0..1	attr	If enabled the default Reachable Time value may be reconfigured based on received Router Advertisements.
tcpIpNdpDynamicRetransTimeEnabled	Boolean	0..1	attr	If enabled the default Retransmit Timer value may be reconfigured based on received Router Advertisements.
tcpIpNdpMaxRandomFactor	PositiveInteger	0..1	attr	Maximum random factor used for randomization
tcpIpNdpMaxRtrSolicitationDelay	TimeValue	0..1	attr	Maximum delay before the first Router Solicitation will be sent after interface initialization in (s).
tcpIpNdpMaxRtrSolicitations	PositiveInteger	0..1	attr	Maximum number of Router Solicitations that will be sent before the first Router Advertisement has been received.

▽

△

Class	**Ipv6NdpProps**			
tcpIpNdpMinRandomFactor	PositiveInteger	0..1	attr	Minimum random factor used for randomization
tcpIpNdpNeighborUnreachabilityDetectionEnabled	Boolean	0..1	attr	Neighbor Unreachability Detection is used to remove unused entries from the neighbor cache. This feature is a basic feature of NDP and should be turned on.
tcpIpNdpNumMulticastSolicitations	PositiveInteger	0..1	attr	Maximum number of multicast solicitations that will be sent when performing address resolution.
tcpIpNdpNumUnicastSolicitations	PositiveInteger	0..1	attr	Maximum number of unicast solicitations that will be sent when performig Neighbor Unreachability Detection.
tcpIpNdpPacketQueueEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of a NDP Packet Queue according to IETF RFC 4861, section 7.2.2.
tcpIpNdpPrefixListSize	PositiveInteger	0..1	attr	Maximum number of entries in the on-link prefix list.
tcpIpNdpRandomReachableTimeEnabled	Boolean	0..1	attr	If enabled the value of ReachableTime will be multiplied with a random value between MIN_RANDOM_FACTOR and MAX_RANDOM_FACTOR in order to prevent multiple nodes from transmitting at exactly the same time.
tcpIpNdpRndRtrSolicitationDelayEnabled	Boolean	0..1	attr	If enabled the first router solicitation will be delayed randomly from [0...MAX_RTR_SOLICITATION_DELAY]. Otherwise the first router solicitation will be sent after exactly MAX_RTR_SOLICITATION_DELAY milliseconds.
tcpIpNdpRtrSolicitationInterval	TimeValue	0..1	attr	Interval between consecutive Router Solicitations in (s).
tcpIpNdpSlaacDadNumberOfTransmissions	PositiveInteger	0..1	attr	Number of Neighbor Solicitations that have to be unanswered in order to set an autoconfigurated address to PREFERRED (usable) state.
tcpIpNdpSlaacDadRetransmissionDelay	TimeValue	0..1	attr	Sets the maximum value for the address configuration delay (s).
tcpIpNdpSlaacDelayEnabled	Boolean	0..1	attr	If enabled transmission of the first DAD Neighbor Solicitation will be delayed by a random value from [0...MAX_DAD_DELAY].
tcpIpNdpSlaacOptimisticDadEnabled	Boolean	0..1	attr	Enable Optimistic Duplicate Address Detection (DAD) according to RFC4429.

⌈If defined, the value of UdpProps.udpTtl shall be in the range of 1..255.⌋

Class	TcpProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class specifies the configuration options for TCP (Transmission Control Protocol).			
Base	*ARObject*			
Aggregated by	EthTcpIpProps.tcpProps			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
tcpCongestionAvoidanceEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of TCP congestion avoidance algorithm according to IETF RFC 5681.
tcpDelayedAckTimeout	TimeValue	0..1	attr	The maximal time an acknowledgement is delayed for transmission in seconds.
tcpFastRecoveryEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of TCP Fast Recovery according to IETF RFC 5681.
tcpFastRetransmitEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of TCP Fast Retransmission according to IETF RFC 5681.
tcpFinWait2Timeout	TimeValue	0..1	attr	Timeout in [s] to receive a FIN from the remote node (after this node has initiated connection termination), i.e. maximum time waiting in FINWAIT-2 for a connection termination request from the remote TCP.
tcpKeepAliveEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) TCP Keep Alive Probes according to IETF RFC 1122 chapter 4.2.3.6.
tcpKeepAliveInterval	TimeValue	0..1	attr	Specifies the interval in seconds between subsequent keepalive probes.
tcpKeepAliveProbesMax	PositiveInteger	0..1	attr	Maximum number of times that a TCP Keep Alive is retransmitted before the connection is closed.
tcpKeepAliveTime	TimeValue	0..1	attr	Specifies the time in [s] between the last data packet sent (simple ACKs are not considered data) and the first keepalive probe.
tcpMaxRtx	PositiveInteger	0..1	attr	Maximum number of times that a TCP segment is retransmitted before the TCP connection is closed. This parameter is only valid if tcpRetransmissionTimeout is configured. Note: This parameter also applies for FIN retransmissions.
tcpMsl	TimeValue	0..1	attr	Maximum segment lifetime in [s].

▽

△

Class	TcpProps			
tcpNagleEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of Nagle's algorithm according to IETF RFC 1122 (chapter 4.2.3.4 When to Send Data). If enabled the Nagle's algorithm is activated per default for all TCP sockets, but can be deactivated per Socket (with the attribute TcpTp.nagleAlgorithm).
tcpReceiveWindowMax	PositiveInteger	0..1	attr	Default value of maximum receive window in bytes.
tcpRetransmissionTimeout	TimeValue	0..1	attr	Timeout in [s] before an unacknowledged TCP segment is sent again. If the timeout is disabled, no TCP segments shall be retransmitted.
tcpSlowStartEnabled	Boolean	0..1	attr	Enables (TRUE) or disables (FALSE) support of TCP slow start algorithm according to IETF RFC 5681.
tcpSynMaxRtx	PositiveInteger	0..1	attr	Maximum number of times that a TCP SYN is retransmitted.
tcpSynReceivedTimeout	TimeValue	0..1	attr	Timeout in [s] to complete a remotely initiated TCP connection establishment, i.e. maximum time waiting in SYN-RECEIVED for a confirming connection request acknowledgement after having both received and sent a connection request.
tcpTtl	PositiveInteger	0..1	attr	Default Time-to-live value of outgoing TCP packets.

3.3.6.8 Ethernet wake-up and sleep on dataline

AUTOSAR supports the wake-up and sleep mechanism that complies with the Open Alliance TC10 specification (OA TC10, see [14]).

[TPS_SYST_03052] Enabling of wake-up and sleep mechanism ⌈The wake-up and sleep mechanism that complies with the Open Alliance TC10 specification (OA TC10) is enabled by defining the reference from CouplingPort to EthernetWakeupSleepOnDatalineConfig in the role wakeupSleepOnDatalineConfig.⌋

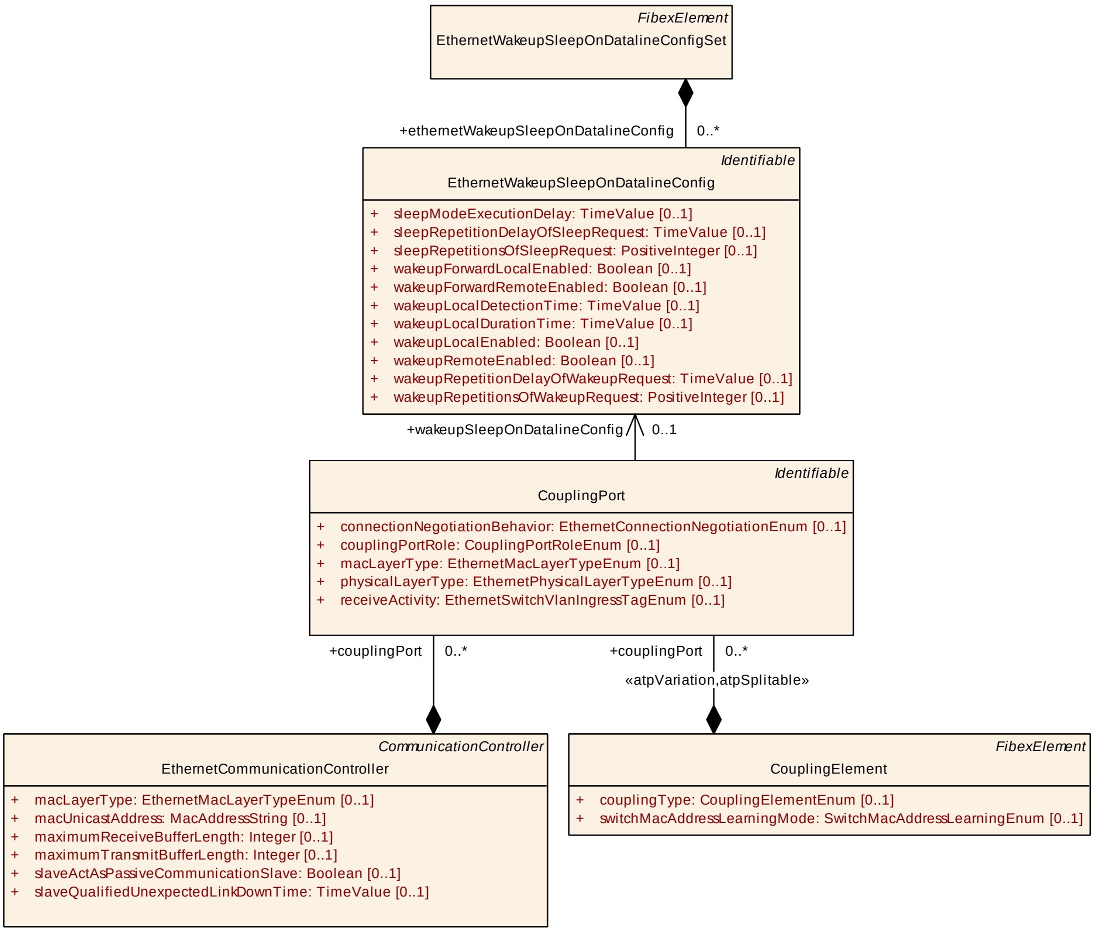

Figure 3.23: Wake on dataline model elements

The OA TC10 specifies service primitives to abstract the Ethernet hardware for ECUs connected via Automotive Ethernet (<bandwith>Base-T1). Drivers use the service primitives to trigger a wake-up and sleep on dataline and react on appropriate indications: *Sleep.request*, *Sleep.indication*, *Wakeup.indication*, *Wakeup.request*, *SleepFail.indication*, and *SleepAbort.request*.

Note:

- *SleepAbort.request* is not considered by AUTOSAR, as the AUTOSAR Network Management ensures a synchronized shutdown on the network. Thus, there is no need for an ECU to reject a *Sleep.request* upon the Network Management.
- *Inhibit.Indication* is not a service primitive, but an optional interface. This optional interface is not considered in AUTOSAR.

Class	**EthernetWakeupSleepOnDatalineConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	EthernetWakeupSleepOnDatalineConfigSet is the main element that aggregates different config set regarding the wakeup and sleep on data line. An EthernetWakeupSleepOnDatalineConfigSet could aggregate multiple different configurations regarding the wakeup and sleep on dataline (EthernetWakeupSleepOnDatalineConfig).			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EthernetWakeupSleepOnDatalineConfigSet.ethernetWakeupSleepOnDatalineConfig			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
sleepMode ExecutionDelay	TimeValue	0..1	attr	Delay in seconds to perform a sleep request if the Ethernet hardware (PHY) detect a pending wake-up. This is used to avoid the race condition, if a sleep was requested while a wake-up of a neighboring PHY was received via a local wake-up connection (e.g. I/O pin).
sleepRepetition DelayOfSleep Request	TimeValue	0..1	attr	Delay in seconds for a repetition of a sleep request. This is used to retry a synchronized shutdown of the connected Ethernet hardware (PHY) of the link partner.
sleep RepetitionsOf SleepRequest	PositiveInteger	0..1	attr	Count of repetitions for a sleep on dataline. If a sleep is rejected by the linked communication partner, the sleep is repeated until the count of repetitions exceed. If count of repetitions exceed, the Ethernet hardware (PHY) transit to sleep without acknowledgement of the connected link partner.
wakeupForward LocalEnabled	Boolean	0..1	attr	If enabled, then a remote wake-up received on the physical dataline (e.g. 100BASE-T1) is forwarded as local wake-up (e.g. via an I/O pin). If disabled, then a remote wake-up is not forwarded as local wake-up.
wakeupForward RemoteEnabled	Boolean	0..1	attr	If enabled, then a local wake-up is forwarded to the physical dataline (e.g. 100BASE-T1). If disabled, then a local wake-up is not forwarded to the physical dataline.
wakeupLocal DetectionTime	TimeValue	0..1	attr	Specify the detection time if a local wake-up in seconds is present on the local wake-up connection (e.g. I/O pin). A local wake-up has to be present at least for wakeupLocal DetectionTime to be detected a valid local wake-up.
wakeupLocal DurationTime	TimeValue	0..1	attr	Specify the duration of a local wake-up in seconds to be present on the local wake-up connection (e.g. I/O pin).
wakeupLocal Enabled	Boolean	0..1	attr	If enabled, then a local wake-up received via a local connection (e.g. I/O pin) shall be detected by the Ethernet hardware (PHY). If disabled, Ethernet hardware is not reacting on a local wake-up.
wakeupRemote Enabled	Boolean	0..1	attr	If enabled, then a remote wake-up received via the physical dataline (e.g. 100BASE-T1) shall be detected by the Ethernet hardware (PHY). If disabled, Ethernet hardware is not reaction on a remote wake-up.
wakeup RepetitionDelay OfWakeup Request	TimeValue	0..1	attr	Delay in seconds for a repetition of a wake-up. This is used to increase the reliability in the network, such that an ECU which initiates the wake-up does repeat the wake-up and increase the probability that affected ECUs receive the wake-up.
wakeup RepetitionsOf Wakeup Request	PositiveInteger	0..1	attr	Count of repetitions for a wake-up. This is used to increase the reliability in the network, such that an ECU which initiates the wake-up does repeat the wake-up and increase the probability that affected ECUs receive the wake-up.

- where the referenced EthernetWakeupSleepOnDatalineConfig has the attribute wakeupLocalDetectionTime defined

shall refer to EthernetWakeupSleepOnDatalineConfigs where the value of wakeupLocalDetectionTime is identical for all referencing CouplingPorts.⌋

Note: [constr_3609] and [constr_3610] ensure the same timing behavior within the used Ethernet hardware (e.g. Ethernet switch), if those CouplingPorts reference different EthernetWakeupSleepOnDatalineConfigs.

[constr_3607] Existence of sleepRepetitionDelayOfSleepRequest

Imposition time: IT_SysDesc

⌈The attribute sleepRepetitionDelayOfSleepRequest shall be defined if sleepRepetitionsOfSleepRequest is defined and has a value greater than 0.⌋

[constr_3608] Existence of wakeupRepetitionDelayOfWakeupRequest

Imposition time: IT_SysDesc

⌈The attribute wakeupRepetitionDelayOfWakeupRequest shall only be defined if wakeupRepetitionsOfWakeupRequest is defined and has a value greater than 0.⌋

Note: The OA TC10 [14] wake-up on dataline feature can be used instead of a wake-up line. The different timing behavior has to be considered. If using a wake-up line, the wake-up pulse is present for all connected ECUs at the same point in time. If using wake-up on dataline, the wake-up (WUP / WUR) has to be forwarded by the receiving Ethernet hardware (PHY). The wake-up is propagated over the network and therefore it is sequentially present for the receiving ECUs.

The following chapters describe the behavior in detail with respect to the OA TC10 service primitives and their modelling in the System Template.

3.3.6.8.1 Ethernet Communication Controller

[constr_3600] Setting of EthernetCommunicationController.slaveActAsPassiveCommunicationSlave

Imposition time: IT_SysDesc

⌈The attribute EthernetCommunicationController.slaveActAsPassiveCommunicationSlave may only be set to TRUE, if the following conditions apply:

- the EthernetCommunicationController is not referenced by any NmNode in the role controller
- the EthernetCommunicationController aggregates at least one CouplingPort
- the couplingPortRole of that CouplingPort is set to standardPort
- the physicalLayerType of that CouplingPort is set to either _100BASE_T1, _1000BASE_T1 or _10BASE_T1S

In all other cases the attribute slaveActAsPassiveCommunicationSlave shall be set to FALSE or shall not be defined.⌋

Note: An Ethernet ECU which aggregates an EthernetCommunicationController that is acting as a passive slave is not using Nm frames for a synchronized shutdown. A synchronized shutdown has to be provided by the used Ethernet hardware. E.g. Ethernet hardware compliant with Open Alliance TC10.

Note further: It is only allowed for Ethernet ECUs which are NOT maintaining an Ethernet switch on the corresponding communication channel to act as a passive slave. A passive slave follows the communication request of the corresponding communication master.

[constr_3611] Existence of EthernetCommunicationController.slaveQualifiedUnexpectedLinkDownTime

Imposition time: IT_SysDesc

⌈The attribute slaveQualifiedUnexpectedLinkDownTime shall be defined if slaveActAsPassiveCommunicationSlave is set to TRUE.⌋

[TPS_SYST_03053] Semantics of EthernetCommunicationController.slaveQualifiedUnexpectedLinkDownTime ⌈EthernetCommunicationController.slaveQualifiedUnexpectedLinkDownTime specifies the time when an unexpected link down is evaluated as link down and indicated to the AUTOSAR communication stack.

If slaveActAsPassiveCommunicationSlave is set to FALSE or not defined, then the communication channel is not acting as a passive communication slave.⌋

The link down time qualification is used for an EthernetCommunicationController where slaveActAsPassiveCommunicationSlave is set to TRUE. The time should cover an error scenario where the corresponding communication master was not able to release the communication by triggering an Sleep.Request (e.g. communication master was unexpectedly reset).

3.3.6.8.2 Service primitives for wake-up

An Ethernet ECU which wants to communicate with other ECUs within the Ethernet switched network topology has to trigger a wake-up on the network to propagate the communication request to the communication partners. The ECU which triggers the wake-up is the requesting ECU. The requesting ECU calls the service primitive *Wakeup.request* to trigger a wake-up. The wake-up is transmitted via the physical dataline (e.g. 100BASE-T1) to the connected link partner. The wake-up could be a wake-up pulse (WUP), if the link to the connected link partner is down, or a wake-up request (WUR), if the link is up (link is already established).

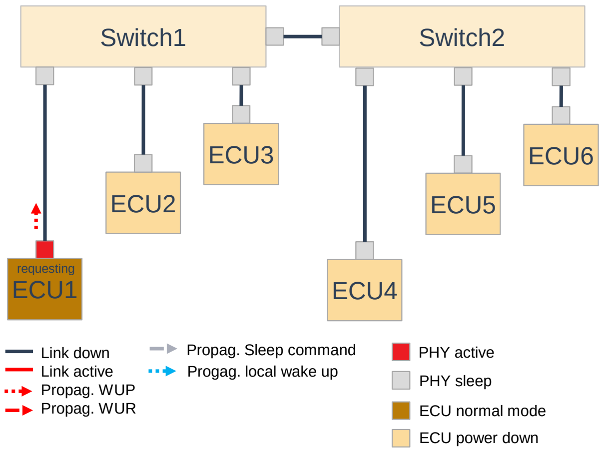

Figure 3.24: While the link is down on the connected dataline, the PHY of ECU1 transmit a wake-up on the network

If a WUP is transmitted by ECU1 and received by the Ethernet hardware (PHY) of Switch1, the receiving Ethernet hardware of Switch1 is woken up. After the receiving Ethernet hardware is initialized, the Switch1 is powered up (INHIBIT pin of power supply is set by the PHY (see OA TC10)) and a *Wakeup.indication* is generated.

(Note: If a WUR is transmitted, the receiving Ethernet hardware (PHY) generates immediately a *Wakeup.indication*, because the receiving Ethernet hardware is already initialized and in normal mode). Simultaneously the received wake-up could be forwarded as local wake-up to the neighboring PHYs of Switch1, if the PHYs are configured accordingly.

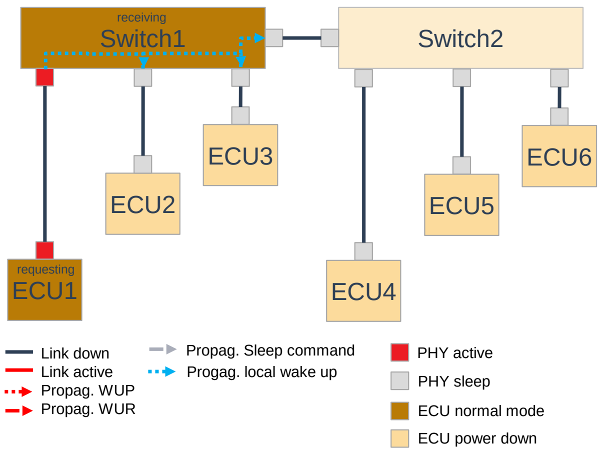

Figure 3.25: Switch1 is woken up by the PHY that received the wake-up. The received wake-up on the network is forwarded as local wake-up to the neighboring PHYs

In multi-PHY and Ethernet switch scenarios, a received wake-up is most likely forwarded to all connected link partners (other datalines) without host ECU (ECU that maintain a Ethernet switch) involvement to fulfill wake-up propagation time requirements.

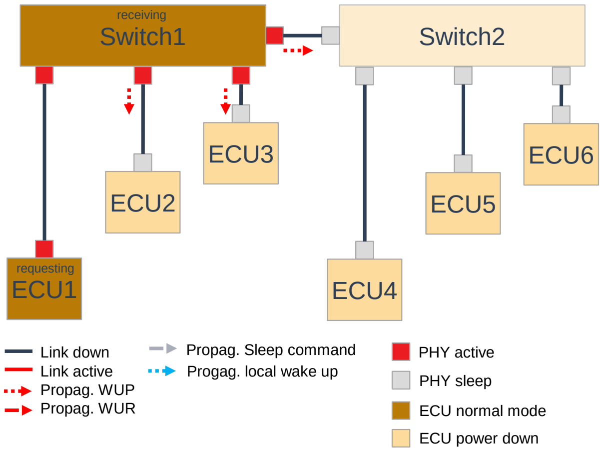

Figure 3.26: The propagated local wake-up is forwarded by the neighboring PHYs as WUP to the connected ECUs (ECU2, ECU3 and Switch2)

The forwarding behavior of each PHY can be modelled in the SystemTemplate. Each PHY is modelled as `CouplingPort`. Each `CouplingPort` could enable the OA TC10 compliant wake-up and sleep on dataline by defining a `wakeupSleepOnDatalineConfig` reference.

3.3.6.8.3 Service primitives for sleep

An ECU which is ready to go to sleep calls the service primitive *Sleep.request* (ECU1). The sleep request is transmitted via the physical dataline (e.g. 100BASE-T1) to the connected communication partner as LPS (low power sleep signal), here Switch1. Please note: LPS are send as continues burst with respect to the specified timing in OA TC10.

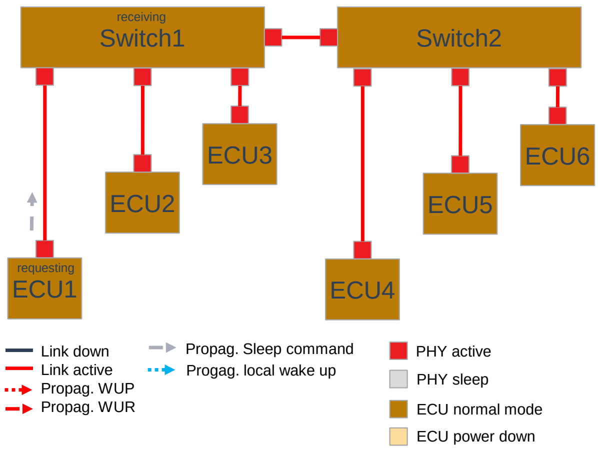

Figure 3.27: ECU1 triggers a *Sleep.request* and the Ethernet hardware of ECU1 sends LPS on the dataline

The receiving Ethernet hardware (PHY) generates a *Sleep.indication* to notify the receiving ECU (here Switch1) that the Ethernet hardware (PHY) of the requesting ECU1 is requesting to go to sleep. The receiving Ethernet hardware (PHY) of the connected communication partner follow the defined PHY power mode sequence described in OA TC10 and acknowledge the received *Sleep.request* with a *Sleep.request* back to requesting ECU (ECU1) with respect to the specified timings in OA TC10.

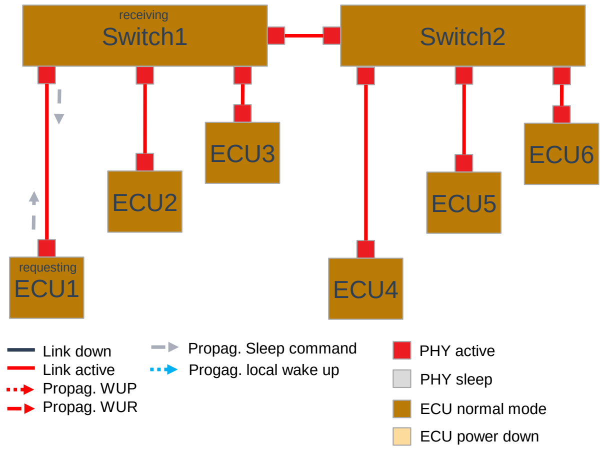

Figure 3.28: Ethernet hardware (PHY) of Switch1 receives LPS and acknowledges the indicated *Sleep.request* of ECU1 by sending back LPS to ECU1

If the requesting ECU (ECU1) received a *Sleep.request* from the receiving ECU (Switch1) within the specified time of OA TC10 the Ethernet hardware of both ECUs (requesting and receiving ECU) transit to sleep state, i.e. the Ethernet hardware of both, ECU1 and Switch1 transit to a low power down mode and the link connection is down.

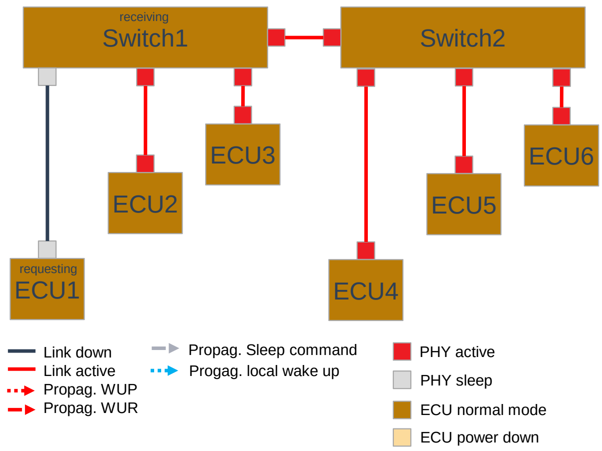

Figure 3.29: ECU1 send and receive LPS with respect to the specified timings in OA TC10 and therefore the Etherent hardware (PHY) of ECU1 and Switch1 transit to a low power sleep mode and the link of the dataline is down

ECUs which participate in an AUTOSAR network management (NM), switch off their communication hardware according to already defined NM shutdown process. Thus, an additional handling in the AUTOSAR stack for an Ethernet communication channel to react on a *Sleep.indication* upon the network management shutdown process is superfluous. The *Sleep.indication* is only evaluated by ECUs which have EthernetCommunicationController.slaveActAsPassiveCommunicationSlave set to TRUE (see details in chapter 3.3.6.8.4).

If the NM decides to go to sleep, then the linked ECUs may switch off their connected hardware at slightly different points in time (e.g. Ethernet switches switch off their Ethernet switch ports with a configured time delay (see couplingPortSwitchoffDelay)). The ECU which earlier switches off the communication hardware will trigger a *Sleep.request*. The connected Ethernet hardware (PHY) of the communication partner will go to sleep according to the defined PHY power mode sequence described in OA TC10. Afterwards the ECU which later switches off its Ethernet hardware has to check the power mode of its Ethernet hardware (PHY). If the Ethernet hardware is already in sleep mode, then the ECU will leave the hardware state as it is and do not trigger a *Sleep.request*. Otherwise the ECU will trigger a *Sleep.request*.

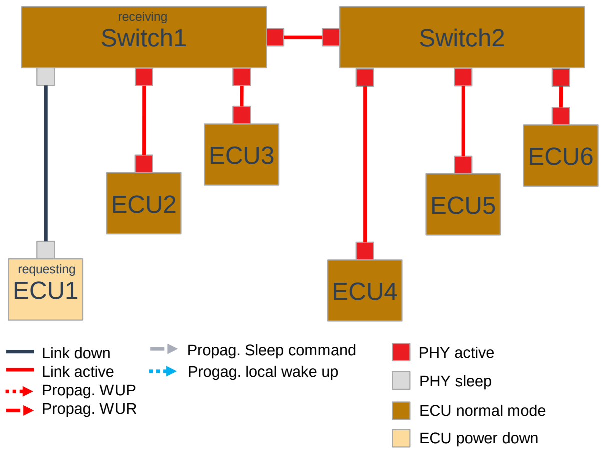

Figure 3.30: ECU1 (requesting ECU) is already in power down mode, while Switch1 is waiting until couplingPortSwitchoffDelay has expired. If couplingPortSwitchoffDelay has expired, Switch1 will detect that the Ethernet hardware is already in sleep state and therefore will NOT trigger a *Sleep.request*

According to the specified service primitive *Sleep.AbortRequest*, the receiving ECU could decide to reject a *Sleep.request* via *Sleep.AbortRequest*. AUTOSAR does NOT support the service primitive *Sleep.AbortRequest*, since the AUTOSAR network management (NM) provide a synchronized shut down of the ECUs. Thus, there is no need to enable an explicit reject of a received *Sleep.request*.

Even though the explicit rejection of a *Sleep.request* is NOT supported, the ECU which requested the *Sleep.request* could be indicated that the *Sleep.request* was NOT accepted by the Ethernet hardware (PHY) of the receiving ECU. If the *Sleep.request* was not acknowledge by Ethernet hardware (PHY) of the receiving ECU, the requesting ECU is signalled via the service primitive *SleepFail.indication*. Reason is an error scenario, where the *Sleep.request* was not received by Ethernet hardware of the receiving ECU or the acknowledgement of the *Sleep.request* back to the requesting ECU was lost on the network (e.g. disturbance of the LPS by a EMC pulse, loose contact of the dataline ... a.s.o.). The ECUs are always evaluating if a *SleepFail.indication* was indicated.

The handling of a detected *SleepFail.indication* is modelled by defining the repetition of a *Sleep.request* (sleepRepetitionsOfSleepRequest) and the delay to re-trigger a *Sleep.request* (sleepRepetitionDelayOfSleepRequest). If the count of repetitions is exceed and *SleepFail.indication* is still signalled, the Ethernet hardware (PHY) is forced to transit to a sleep state and indicate the upper layer of the AUTOSAR communication stack a *Sleep.indication*. This should prevent the requesting ECU to be kept awake if no *Sleep.request* was acknowledged by the receiving ECU.

3.3.6.8.4 Ethernet communication channel that act as passive communication slave

ECUs which are connected to communication channels that do not participate in the AUTOSAR network management can be controlled by a master / slave relationship. The connected Ethernet communication channel is controlled by using the following service primitives: *Wakeup.request*, *Wakeup.indication*, *Sleep.request*, and *Sleep.indication*.

A host ECU (Ethernet ECU which maintains an Ethernet switch) requests to wake-up an Ethernet communication channel of a connected ECU where the corresponding EthernetCommunicationController has set slaveActAsPassiveCommunicationSlave to TRUE (passive communication slave) by triggering a *Wakeup.request*. The wake-up brings the Ethernet hardware (PHY) of the receiving ECU from a sleep mode to a normal mode. The receiving ECU is powered on and its application may provide data which is consumed by the requesting ECU (communication master).

If the requesting ECU (communication master) decides to shutdown the communication channel, the host ECU request the communication channel to go to sleep by triggering a *Sleep.request*. The requested *Sleep.request* is received by the connected ECU on the communication channel with acts as a communication slave. The received *Sleep.request* will be acknowledged by the Ethernet hardware (PHY) of the receiving ECU (passive communication slave) and simultaneously a *Sleep.indication* is signalled. The receiving ECU evaluates the *Sleep.indication*.

If a *Sleep.indication* is detected, this indication is forwarded to the communication stack and the affected communication channel is released. Additionally the application could be indicated about the communication release to execute some shut down actions. Thus, an Ethernet communication channel which acts as passive communication slave, always follows the *Wakeup.indication*/*Sleep.indication* of the corresponding communication master. To cover an error scenario where the communication master could not trigger a *Sleep.request*, due to unexpected reset, the receiving ECU, where an Ethernet channel is acting as passive communication slave, has to detect a link down. If an unexpected link down last longer than slaveQualifiedUnexpectedLinkDownTime, the Ethernet channel, which is acting as passive communication slave, is released autonomously by the receiving ECU.

3.3.7 10BASE-T1S Ethernet

10BASE-T1S is a 10Mbps Single pair Ethernet physical layer technology that is specified by IEEE 802.3cg. The multi-drop feature of 10BASE-T1S allows the usage of a single bus-line to connect ECUs. The PLCA (Physical Layer Collision Avoidance) mechanism avoids collision on PHY level and offers a fair medium access to every participant.

All nodes are identified on the bus via nodeIDs (plcaLocalNodeId) starting from 0 (standardized as the referenced head-node). The Head-Node on the PLCA based network controls the traffic on the bus.

[TPS_SYST_02299] Modeling of 10Base-T1S networks ⌈The modeling of a 10BASE-T1S bus in a System Description is done with a CouplingPortConnection that points with the nodePort reference to CouplingPorts that represent the 10Base-T1S PHYs connected to the network.⌋

[constr_5157] Mixing of Point-To-Point and Multi-Drop is not allowed in a CouplingPortConnection

Imposition time: IT_SysDesc

⌈The CouplingPortConnection is allowed to reference a CouplingPort either:

- in the role firstPort and/or secondPort or
- in the role nodePort

⌋

In other words a CouplingPortConnection shall not use the firstPort and/or secondPort reference (Point-to-Point) and the nodePort reference (Multi-Drop) at the same time.

The PLCA runs cycles on the network. Within each cycle each node with a unique plcaLocalNodeId is assigned with a transmit opportunity. The plcaTransmitOpportunityTimer is identical for all nodes and is therefore configured in the CouplingPortConnection.

The cycle starts with a BEACON that is sent by the head node. During the transmit opportunity the node is able to transmit data or to skip its transmit opportunity. If a node does not need to transmit data the next node is allowed to start its transmit opportunity earlier.

At each BEACON reception client nodes restart their currentNodeID counter and increment it every time a Transmit Opportunity is used or yield. If the currentNodeID matches the plcaLocalNodeId, the corresponding node is allowed to transmit an Ethernet frame for this Transmit Opportunity. The plcaTransmitOpportunityTimer is reset for every Transmit Opportunity once the transceiver detects activity on the bus and recognizes the transmission of data. At each Transmit Opportunity no more than one single Ethernet frame will be sent. On the other hand, if a node has the necessity to sent more packets in one Transmit Opportunity, a burst mode can be used. The burst mode is configured by plcaMaxBurstTimer and plcaMaxBurstCount.

[TPS_SYST_02300] Enabling of PLCA on a CouplingPort ⌈The PLCA (Physical Layer Collision Avoidance) mechanism is enabled on a CouplingPort if the plcaProps are aggregated by the same CouplingPort.⌋

Class	**PlcaProps**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	This meta-class allows to configure the PLCA (Physical Layer Collision Avoidance) in case 10-BASE-T1S Ethernet is used and PLCA is enabled on the CouplingPort (PHY).			
Base	*ARObject*

⌋

3.3.8 MACsec

MACsec (Media Access Control security) is defined by IEEE standard 802.1AE and operates at the medium access control layer and defines connectionless data confidentiality and integrity for media access independent protocols. The MACsec standard specifies a set of protocols to meet the security requirements for protecting data traversing Ethernet LANs. MACsec allows unauthorized LAN connections to be identified and excluded from communication within the network. In common with IPsec and TLS, MACsec defines a security infrastructure to provide data confidentiality, data integrity and data origin authentication. With security on the MAC layer, protocols not based on IP as well as protocols using multicast can be protected by MACsec.

The MACsec standard relies on the usage of authentic partners, which are called MAC Security Entities (SecYs). The standard organizes this by MACsec Protocol Data Units (MPDU), which resides in the MAC layer (ISO/OSI layer 2). The MAC Security Key Agreement Entity (KaY) will take care of properly configuring and managing of the MAC Security Entities to enable the secure communication channel.

In the System Description the configuration of MACsec is supported on CouplingPorts that in turn are aggregated either by a CouplingElement or by an EthernetCommunicationController. This allows the configuration of MACsec on a switch port or on an EthernetCommunicationController of an EcuInstance. Please note that the same modeling approach is used in the Adaptive Platform Manifest as well.

[TPS_SYST_02386] MACsec configuration ⌈A CouplingPort that aggregates the MacSecProps in the role macSecProps defines a MAC Security Entity.⌋

[constr_5361] MACsec configuration is allowed only on switch ports

Table 3.135: MacSecFailPermissiveModeEnum

For MACsec to start up, a key distribution based on MAC Security Key Agreement runs first. The pre-shared key is identified by the ckn. While one might choose only to communicate encrypted, the key distribution itself needs to be unencrypted but integrity protected. In addition, user may choose to allow additional Ethernet frames unprotected, e.g., for installing keys into ECUs. These frames can be selected via so-called bypass rules based on e.g., EtherType or VLAN-ID defined in MacSecGlobalKayProps.

Each MacSecKayParticipant that is referenced by MacSecLocalKayProps in the role mkaParticipant defines the Connectivity Association Key and the MacSecCryptoAlgoConfig. The MacSecKayParticipant settings in the connectivity association need to match on both CouplingPorts of the link to enable MACsec.

For better control and predictability, the MAC Security Key Agreement participant that will get the KeyServer role (the node generating the MACsec Key for this link) can be configured by role.

3.3.9 CDD

The System Template allows the integration of custom bus systems on the topology level.

3.4 Mapping of Topology Entities onto Hardware Elements

As explained in the previous sections, the System Template contains all classes necessary to describe the physical topology in an AUTOSAR system. Based on this description, the communication matrix can be realized as explained in chapter 6.

[TPS_SYST_01019] Mapping of topology elements to elements of the ECU Resource Template

Upstream requirements: RS_SYST_00006

⌈It is possible to map the hardware related topology elements onto their counterpart definitions in the ECU Resource Template.⌋

It can be specified which `HwElement` is realizing each given `EcuInstance`, providing the means for algorithms to map software components onto the systems `EcuInstance`. By specifying which `hwCommunicationPort`[3] on a `hwCommunicationController`[4] implements the topology's `CommunicationConnector` on a `CommunicationController`, the hardware-oriented parameters in the Communication-drivers may be derived in ECU configuration phase.

Please note that this is a rather specific type of mapping, optionally binding ECU-local topology elements to specific hardware resources. It should not be confused with the System Mapping part of the System Description, where system-wide mapping decisions are described, like e.g. the mapping of Software Components onto ECUs or the

[3] `HwPinGroup` which is of category Communication Port
[4] `HwElement` which is of category Communication Controller

mapping of Data Element Prototypes onto System Signals (for the System Mapping, see chapter 5).

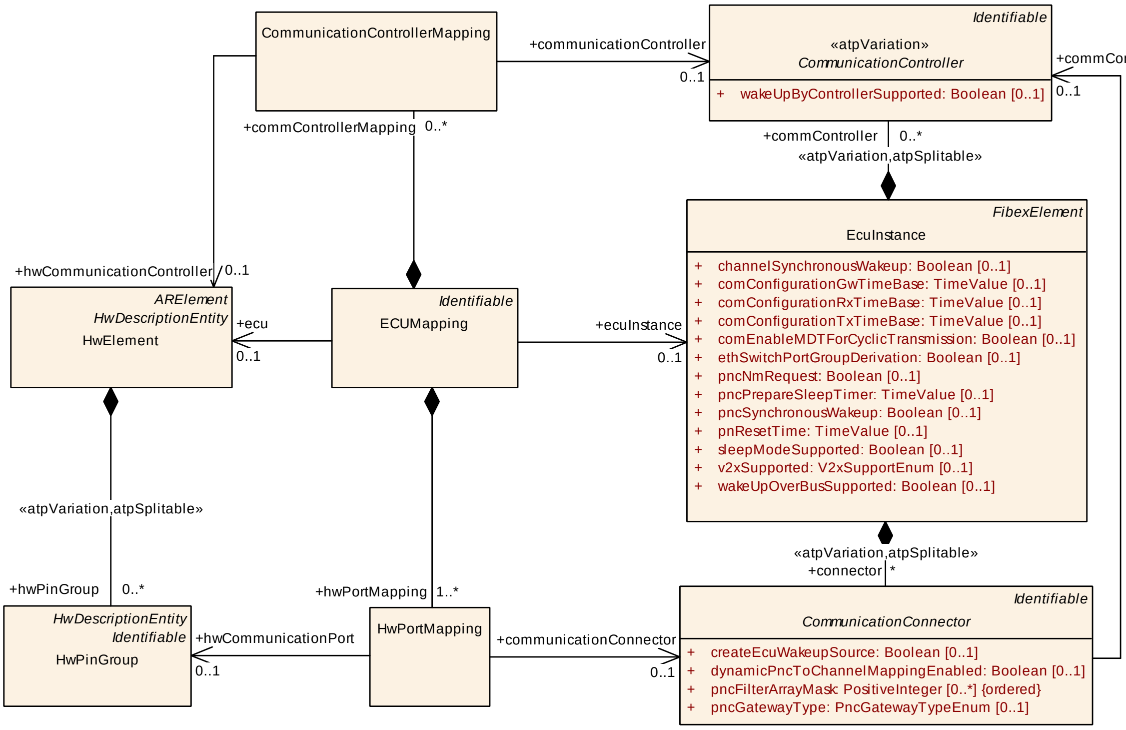

Figure 3.34: Mapping of topology description elements in the System Template onto hardware elements defined in the ECU Resource Template (ECUResourceMapping)

[constr_3006] valid EcuMapping

Imposition time: IT_SysDesc

⌈The referenced hwCommunicationController and hwCommunicationPort shall be part of the referenced ecu.

ECUMapping.ecu.nestedElement contains ECUMapping.commControllerMapping.hwCommunicationController

ECUMapping.ecu.nestedElement contains ECUMapping.hwPortMapping.hwCommunicationPort⌋

3.4.1 ECU Mapping

ECUMapping allows to assign a HwElement to an EcuInstance used in a physical topology.

[TPS_SYST_01013] EcuInstance stands for its own

Upstream requirements: RS_SYST_00013

⌈An EcuInstance can be defined in a stand alone and reusable way without a need to have an ECUMapping.⌋

[constr_3030] valid relationship between ECUMapping and EcuInstance

Imposition time: IT_SysDesc

⌈If an EcuInstance is assigned to a HwElement the EcuInstance shall belong to the same System as the ECUMapping.⌋

[constr_3248] Category of HwElement for ECUMapping

Imposition time: IT_SysDesc

⌈The HwElement which is referenced from ECUMapping in the role ecu shall be of category MicroController⌋

There exists an inconsistency between the System Template and the ECU Resource Template concerning the usage of the term "Ecu". In the System Template "Ecu" is used to determine one instance of an AUTOSAR Stack (e.g. like in EcuInstance). In the Ecu Resource Template "Ecu" is used to describe the physical box (HwElement of category Ecu) containing the electronics which may contain several processing units with several AUTOSAR Stack instances running.

Imposition time: IT_SysDesc

⌈For each HwPortMapping, the reference to HwPinGroup in the role hwCommunicationPort shall exist.⌋

4 Top-level Software Composition

One of the most important inputs for the System Generator is the knowledge about the Application Software Components, their communication capabilities and the connections between them: Each SystemSignal (chapter 6.2) that is going to be exchanged between mapped Software Components onto different ECUs is a consequence of a connection between such application Software Components.

In AUTOSAR, Software Components can either be atomic (AtomicSwComponentType) or may consist of a composition of other Software Components CompositionSwComponentType [4]. In order to assemble non-trivial applications from AUTOSAR components, such compositions can be built up hierarchically, until the outermost CompositionSwComponentType forms a kind of top-level composition.

[constr_3031] Complete System Description does not have ports on the outermost composition

Imposition time: IT_SysDesc

⌈In a complete System with category ABSTRACT_SYSTEM_DESCRIPTION or System with category SYSTEM_DESCRIPTION this outermost CompositionSwComponentType has the unique feature that it doesn't have any outside ports, but all the SWC contained in it are connected to each other and fully specified by their SwComponentTypes, PortPrototypes, PortInterfaces, VariableDataPrototypes, InternalBehavior etc.⌋

[TPS_SYST_01016] System Extract, Ecu System Description and Ecu Extract may have ports

Upstream requirements: RS_SYST_00027

⌈In a System with category SYSTEM_EXTRACT and a System with category ECU_SYSTEM_DESCRIPTION and a System with category ECU_EXTRACT outside ports for the outermost composition are allowed.⌋

[TPS_SYST_02312] Ports for outermost composition of a SW_CLUSTER_SYSTEM_DESCRIPTION ⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION outside ports for the outermost composition are allowed.⌋

Since the System/Ecu Extract represents the view on one Ecu, there may be the need to define the communication of this extract with the outside world.

Two approaches are available how the external communication of an ECU in the System Extract is described. In section 13.2 the communication mapping is performed in the hierarchical structure of software components. In section 13.3 external communication delegation ports are added to the System extract outermost composition.

Each delegated port is connected via a DelegationSwConnector with ports of the included components that are used for the external communication.

A System considers such a top-level CompositionSwComponentType as its application software system input by owning exactly one RootSwCompositionPrototype class, which points to the CompositionSwComponentType forming the input via its ≪isOfType≫ relationship as shown in Figure 2.1.

[TPS_SYST_01017] The role of the top-level software composition

Upstream requirements: RS_SYST_00006

⌈An AUTOSAR System uses the specialized prototype class RootSwCompositionPrototype in order to designate the referenced CompositionSwComponentType as the top-level software composition.⌋

Class	**RootSwCompositionPrototype**			
Package	M2::AUTOSARTemplates::SystemTemplate			
Note	The RootSwCompositionPrototype represents the top-level-composition of software components within a given System. According to the use case of the System, this may for example be a more or less complete VFB description, the software of a System Extract or the software of a flat ECU Extract with only atomic SWCs. Therefore the RootSwComposition will only occasionally contain all atomic software components that are used in a complete VFB System. The OEM is primarily interested in the required functionality and the interfaces defining the integration of the Software Component into the System. The internal structure of such a component contains often substantial intellectual property of a supplier. Therefore a top-level software composition will often contain empty compositions which represent subsystems. The contained SwComponentPrototypes are fully specified by their SwComponentTypes (including Port Prototypes, PortInterfaces, VariableDataPrototypes, SwcInternalBehavior etc.), and their ports are interconnected using SwConnectorPrototypes.

⌈For each RootSwCompositionPrototype, the reference to CompositionSwComponentType in the role softwareComposition shall exist.⌋

5 Mapping

A central part of the system generation process is the mapping of software components (SwComponentPrototypes) to ECUs, and the subsequent mapping of the communication between these software components to bus frames. Input to the software component mapping is the RootSwCompositionPrototype, which describes which software components have to be mapped, and the System Topology, which defines the ECU instances that are available as mapping targets. Once this mapping is done, also the communication matrix has to be taken into account for the next mapping step, the mapping of data elements exchanged between software components to bus frames. This communication matrix may either be predefined, or may be generated as part of this second mapping step. In the metamodel, different aspects of these mapping are aggregated by the meta class SystemMapping, as shown in Figure 5.1.

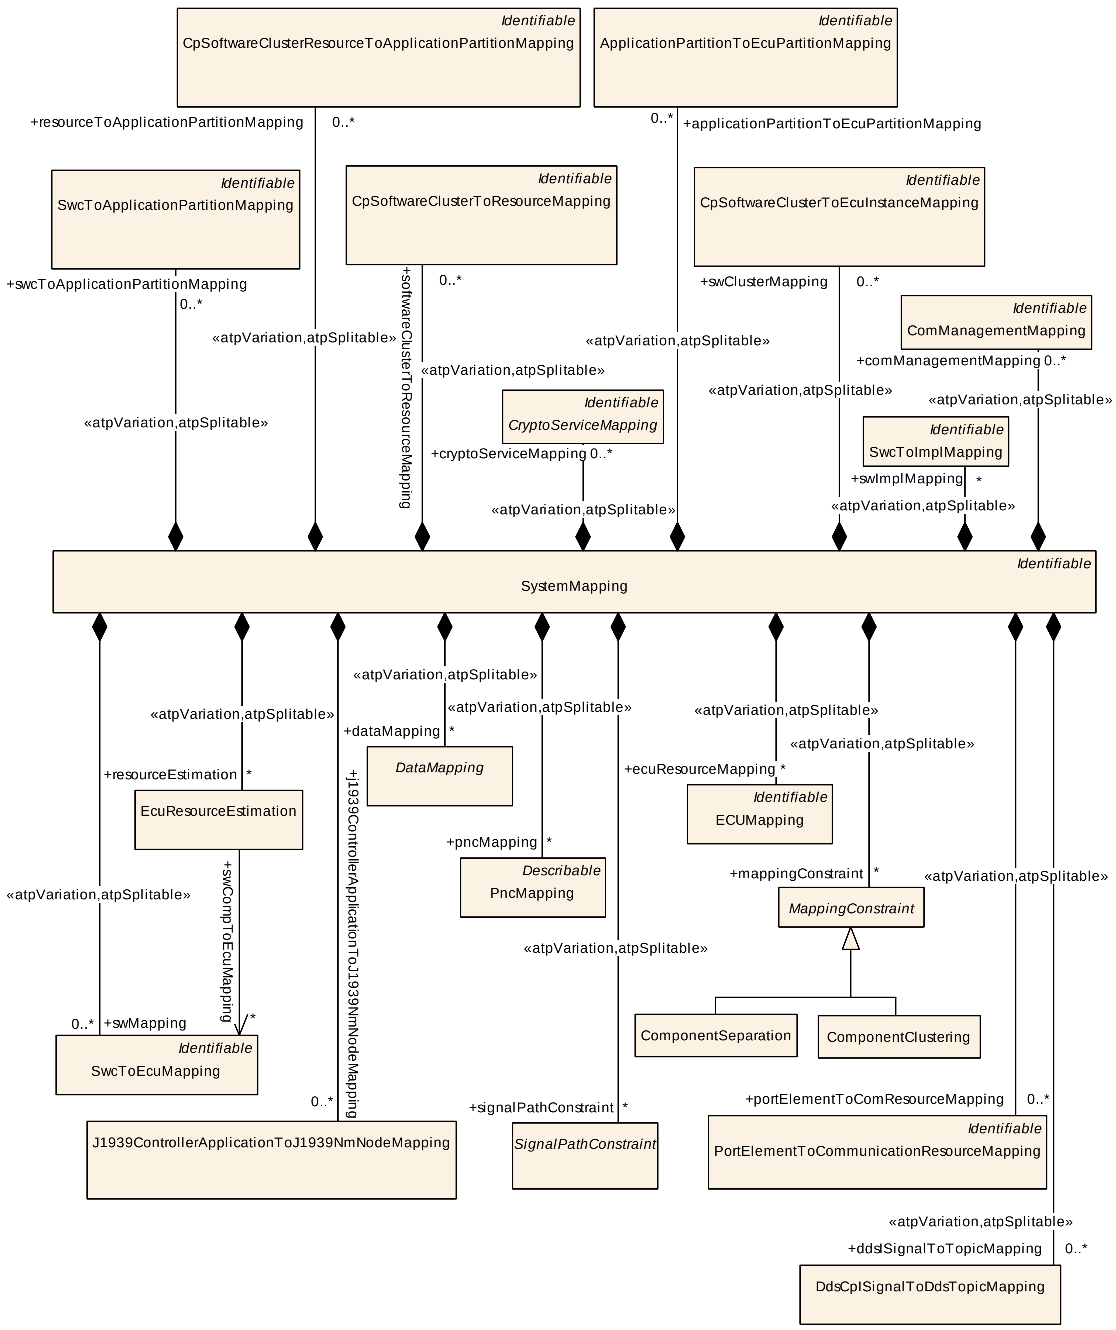

Figure 5.1: Mapping Overview (Mapping)

The following mappings are defined:

- The SwcToEcuMapping meta-class maps one or several SwComponentPrototypes to ECUs. In the System Constraint Description it is possible to predefine the mapping of SwComponentPrototypes to ECUs. The predefinition limits the system architect's freedom to map software components to arbitrary ECUs. After the system generation in the System Configuration Description, all atomic software components that are directly or indirectly part of the top level composition shall be mapped with this mapping rule. Software component mapping is described in detail in chapter 5.1.

- The meta-class EcuResourceEstimation specifies the resource estimation for RTE and basic software (see chapter 5.3).

- The ECUMapping meta-class is used to map the hardware related topology elements onto their counterpart definitions in the ECU Resource Template (see chapter 3.4).

- The DataMapping meta-class is used to map VariableDataPrototypes and ClientServerOperations in software component ports (i.e. the data exchanges between software components) to signals. The data mapping is described in detail in chapter 5.2.

- The ComManagementMapping defines the mapping of one or several Mode Management PortGroups and communication channels (see chapter 5.4.2).

- The PncMapping defines the Partial Network behavior (see chapter 5.4.1).

- The SignalPathConstraint meta-class is used to define which specific way a signal (data element or client server operation arguments) between two Software Components should take in the network without defining in which frame and with which timing it is transmitted. This Signal Path Constraint is introduced in chapter 5.2.2.

- The MappingConstraint meta-class is used to define constraints that constrain the mapping of software components. It's sub-classes allow to constraint which SwComponentPrototypes shall be mapped together on the same ECU (ComponentClustering) and which shall not be mapped to the same ECU (ComponentSeparation). The mapping constraints are described in detail in chapter 5.1.4.

- The J1939ControllerApplicationToJ1939NmNodeMapping maps a Software Component to which a standardized function id is assigned to a J1939NmNode (see chapter 5.1.5)

- The CpSoftwareClusterToEcuInstanceMapping meta-class maps a CpSoftwareCluster to an EcuInstance (see chapter 5.5)

- The CpSoftwareClusterToResourceMapping meta-class maps a CpSoftwareClusterServiceResource to CpSoftwareClusters (see chapter 11.2)

- The CpSoftwareClusterResourceToApplicationPartitionMapping meta-class maps a Software Cluster resource to an Application Partition (see chapter 5.5)
- The SwcToImplMapping meta-class is used to assign one Implementation to one or more SwComponentPrototypes (see chapter 5.1.2).
- The Class DdsCpISignalToDdsTopicMapping is used to assign one DdsCpTopic to one ISignals). To map one ISignal to more than one DdsCpTopic (Fan-Out), multiple DdsCpISignalToDdsTopicMapping are used. For any details, see chapter 5.6.

Table 5.1: SystemMapping

5.1 Software Component Mapping

A fundamental concept of AUTOSAR is that SW components may be developed independently of a specific ECU hardware, and can be mapped to an ECU in the AUTOSAR System Generation Process. The System Constraint Description acts as an input to this System Generation Phase. Nevertheless, there may be some SW components which are already mapped due to previous iterations of the system generation step, and there may be system constraints that limit the system architect's freedom to map SW components to arbitrary ECUs. In the following, the individual elements are described in more detail.

Please note that the purpose of [constr_5116] is to support the unambiguous mapping of symbols in memory sections. In the AUTOSAR Basic Software, the namespace of a Bsw Module is allocated case insensitive in order to support the definition of symbols in solely upper case notation.

[constr_5116] Uniqueness of the symbols of software-components and BSW modules

Imposition time: IT_EcuExt

⌈For all SwComponentPrototypes typed by an ApplicationSwComponentType, NvBlockSwComponentType or SensorActuatorSwComponentType mapped to a given EcuInstance by means of SwcToEcuMapping respectively SwcToApplicationPartitionMapping and ApplicationPartitionToEcuPartitionMapping the following restriction applies:

The symbolic name of an AtomicSwComponentType referenced by a respective SwComponentPrototype in the role type shall not overlap with the module implementation prefix (MIP) of any of the basic software-modules existing on the EcuInstance.

The symbolic name of an AtomicSwComponentType is derived from the value of

- AtomicSwComponentType.symbol, or if this attribute does not exist
- AtomicSwComponentType.shortName.

⌋

More information about the nature and usage of the symbolic name of a software-component can be found in [TPS_SWCT_01110], [TPS_SWCT_01000], and [TPS_SWCT_01635].

The restriction in [constr_5116] does not apply for ServiceSwComponentTypes, ComplexDeviceDriverSwComponentTypes, and EcuAbstractionSwComponentTypes. The reason is that for the Basic Software that utilizes standardized Interfaces and AUTOSAR Interfaces needs a SwComponentType and a Basic Software Description to describe both kinds of Interfaces but only one header file for memory allocation is expected. So for example the definition of a “Dem” Service SWC and a “Dem” Basic Module Description defines a legal naming in AUTOSAR.

5.1.1 SW Component to ECU Mapping

[TPS_SYST_01001] Definition of SwcToEcuMapping

Upstream requirements: RS_SYST_00007

⌈With the SwcToEcuMapping element it is possible to express the mapping of SwComponentPrototypes to one EcuInstance or optional to individual HwElements with category Processing Unit residing in this ECU. An optional assignment of Sensor/Actuator SwComponentPrototypes to Sensor/Actuator HwElements is also possible.⌋

[constr_5486] Existence of SwcToEcuMapping.component

Imposition time: IT_SysDesc

⌈For each SwcToEcuMapping, the reference to SwComponentPrototype in the role component shall exist.⌋

[constr_5487] Existence of SwcToEcuMapping.ecuInstance

Imposition time: IT_SysDesc

⌈For each SwcToEcuMapping the reference to EcuInstance in the role ecuInstance shall exist.⌋

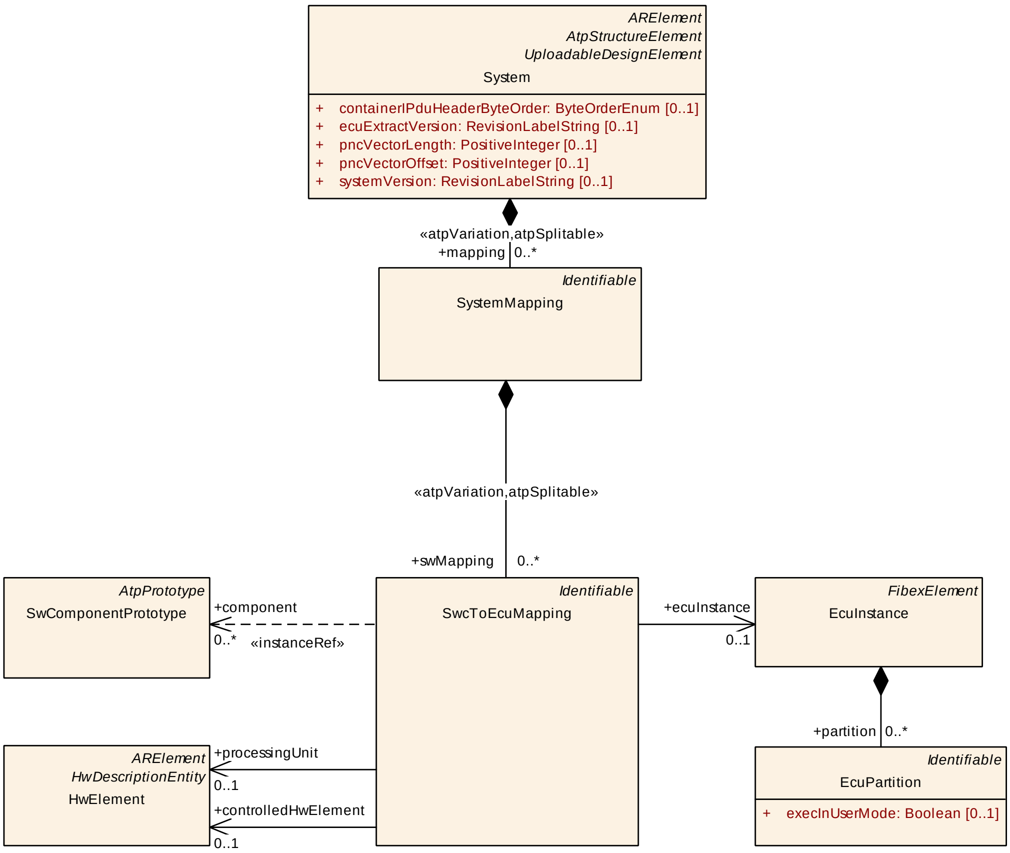

Figure 5.2: SW component to ECU mapping (SwcToEcuMapping)

The SwcToEcuMapping collects a list of all SwComponentPrototypes that shall be deployed onto the associated SwcToEcuMapping targets.

[TPS_SYST_02114] Mapping of SwComponentPrototypes onto SwcToEcuMapping targets

Upstream requirements: RS_SYST_00007

⌈The SwcToEcuMapping of SwComponentPrototypes to

- EcuInstance

- processingUnit
- controlledHwElement

is arbitrary.

It is equivalent to either

- have several SwcToEcuMappings which map a set of SwcToEcuMapping.components to a SwcToEcuMapping.ecuInstance, SwcToEcuMapping.processingUnit, SwcToEcuMapping.controlledHwElement,
- or one SwcToEcuMapping which maps the set of SwcToEcuMapping.components at once.

⌋

[constr_3263] Restriction of usage of SwcToEcuMapping in a System

Imposition time: IT_SysDesc

⌈For all SwcToEcuMappings in a System the following restriction applies: No two SwcToEcuMappings shall have the exact same reference to

- SwComponentPrototype
- EcuInstance
- processingUnit
- controlledHwElement

⌋

SwcToEcuMapping may map either prototypes of AtomicSwComponentType or those of CompositionSwComponentType.

[TPS_SYST_01020] Unconditional mapping of atomic Software Components

Upstream requirements: RS_SYST_00007

⌈In case a prototype of an atomic Software Components is mapped, the mapping is unconditional.⌋

[TPS_SYST_01021] Mapping of CompositionSwComponentType

Upstream requirements: RS_SYST_00007

⌈In case a mapped SwComponentPrototype refers to a CompositionSwComponentType, the mapping is applied to any inner SwComponentPrototype recursively; however, it may be overwritten by additional SwcToEcuMapping mapping inner SwComponentPrototype to different EcuInstances.⌋

Usually a particular component prototype can be mapped explicitly to at most one ECU in a given system (leaving aside variant handling and the implicit mapping of "inner" prototypes mentioned above) but there are two exceptions:

- **[TPS_SYST_01022] Prototype of a ParameterSwComponentType can be mapped to more than one ECU**

  Upstream requirements: RS_SYST_00007

  ⌈A prototype of a ParameterSwComponentType can be mapped to more than one ECU. This is required, because this special component does not communicate over the network, so that a copy of the prototype has to be created on each ECU were it is required.⌋

- **[TPS_SYST_01023] Prototype of an ServiceProxySwComponentType can be mapped to more than one ECU**

  Upstream requirements: RS_SYST_00031

  ⌈A prototype of an ServiceProxySwComponentType can be mapped to more than one ECU even if it appears only once in the VFB system, because a prototype of this special component is required on each ECU, for which local Services are addressed via the proxy.⌋

[constr_3021] Mapping of SensorActuatorSwComponents to SensorActuator HwElements

Imposition time: IT_EcuExt

⌈Only SwComponentPrototypes that are typed by SensorActuatorSwComponentType shall be mapped to a HwElement with category SensorActuator via the controlledHwElement relation.⌋

[constr_3249] Category of HwElement for SwcToEcuMapping

Imposition time: IT_EcuExt

⌈The HwElement which is referenced from SwcToEcuMapping in the role processingUnit shall be of category "ProcessingUnit".⌋

The following table describes the SwcToEcuMapping in detail.

Class	**SwcToEcuMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	This meta-class is used: • to map SwComponentPrototypes to a specific ECU Instance unit, • optionally to map SwComponentPrototypes to a HwElement with category ProcessingUnit, • optionally to map SwComponentPrototypes typed by SensorActuatorSwComponentType to a Hw Element with category SensorActuator. For each combination of ECUInstance and the optional ProcessingUnit and the optional SensorActuator only one SwcToEcuMapping shall be used.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SystemMapping.swMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
component	SwComponent Prototype	*	iref	References to the software component instances that are mapped to the referenced ECUInstance. If the component prototype referenced is a composition, this indicates that all atomic software components within the composition are mapped to the ECU. If there is aditionally a mapping of some SwComponent Prototype INSIDE the Composition to another ECU Instance the inner mapping overrides the outer mapping. **InstanceRef implemented by:** ComponentInSystem InstanceRef
controlledHw Element	HwElement	0..1	ref	Optional mapping of SwComponentPrototypes that are typed by SensorActuatorSwComponentType to a Hw Element with category SensorActuator.
ecuInstance	EcuInstance	0..1	ref	Reference to a specific ECU Instance description.
processingUnit	HwElement	0..1	ref	Optional mapping of software components to individual microcontroller cores residing in one ECU. A microcontroller core is described in the ECU Resource Template by the HwElement of HwCategory Processing Unit.

Table 5.2: SwcToEcuMapping

5.1.2 Software Component to Implementation Mapping

As several implementations may exist for the same AtomicSwComponentType, it needs to be decided on and specified which instances of a given AtomicSwComponentType are mapped to which Implementation. According to the AUTOSAR Methodology this information can either be added within the Configure System activity, or later when the RTE part is configured during Configure ECU phase. If the mapping is done in System Configuration, a SwcToImplMapping is being used for assigning one Implementation to one or more instances of SwComponentPrototype relating to the same AtomicSwComponentType. This is illustrated in Figure 5.3.

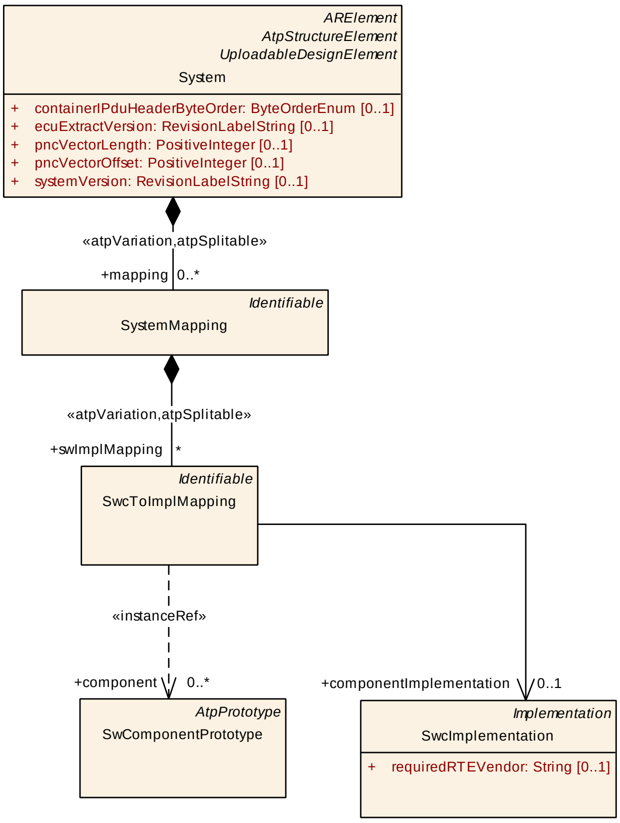

Figure 5.3: SW Component to Implementation mapping (SwcToImplMapping)

[constr_3002] valid swcToImplMapping

Imposition time: IT_EcuExt

⌈The referenced SwcImplementation refers to a SwcInternalBehavior that is part of a AtomicSwComponentType. The same AtomicSwComponentType shall be the type of the referenced SwComponentPrototype.

SwcToImplMapping.componentImplementation.behavior.component == SwcToImplMapping.component.type⌋

The following table contains the detailed description of SwcToImplMapping:

Class	SwcToImplMapping			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	Map instances of an AtomicSwComponentType to a specific Implementation.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SystemMapping.swImplMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
component	SwComponent Prototype	*	iref	Reference to the software component instances that are being mapped to the specified Implementation. The targeted SwComponentPrototype needs be of the Atomic SwComponentType being implemented by the referenced Implementation. **InstanceRef implemented by:** ComponentInSystem InstanceRef
component Implementation	SwcImplementation	0..1	ref	Reference to a specific Implementation description. Implementation to be used by the specified SW component instance. This allows to achieve more precise estimates for the resource consumption that results from mapping the instance of an atomic SW component onto an ECU.

Table 5.3: SwcToImplMapping

[constr_5488] Existence of SwcToImplMapping.component

Imposition time: IT_EcuExt

⌈For each SwcToImplMapping, the reference to SwComponentPrototype in the role component shall exist at least once.⌋

[constr_5489] Existence of SwcToImplMapping.componentImplementation

Imposition time: IT_EcuExt

⌈For each SwcToImplMapping, the reference to SwcImplementation in the role componentImplementation shall exist.⌋

5.1.3 SW Component to Partition Mapping

With the SwcToApplicationPartitionMapping and the ApplicationPartitionToEcuPartitionMapping an OEM has the option to predefine an allocation to memory partitions in the System Design phase. The final and complete assignment is described in the OS Configuration. The SwcToApplicationPartitionMapping defines a mapping to ApplicationPartitions that allows an allocation to a formally defined partition at a point in time when the EcuInstance is not yet known or defined. In a later methodology step this assignment can be refined with the ApplicationPartitionToEcuPartitionMapping to an EcuPartition defined in the context of an EcuInstance.

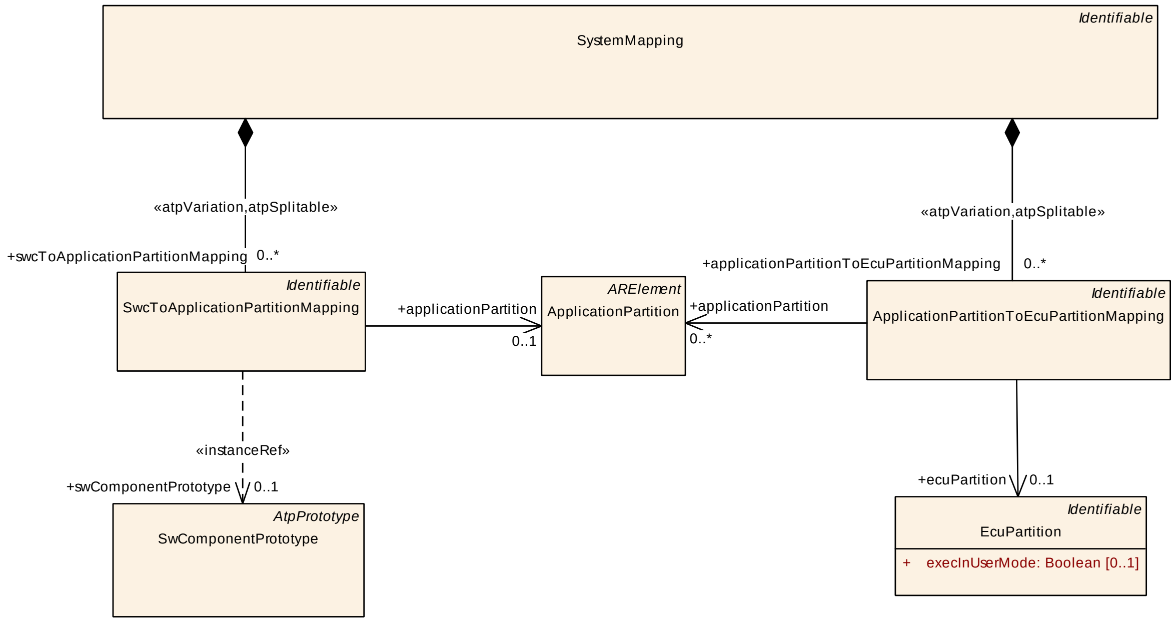

Figure 5.4: SW Component to Application Partition mapping

Class	**SwcToApplicationPartitionMapping**

[constr_3229] SwComponentPrototype mapped to an ApplicationPartition and EcuInstance

Imposition time: IT_EcuExt

⌈If the SwcToEcuMapping.ecuInstance exists then a SwComponentPrototype that is mapped to an ApplicationPartition via the SwcToApplicationPartitionMapping shall only be mapped by an ApplicationPartitionToEcuPartitionMapping to an EcuPartition that is aggregated by the EcuInstance referenced by means of SwcToEcuMapping.ecuInstance.⌋

5.1.4 Software Component Mapping Constraints

In contrast to the mapping description described in the previous chapters, mapping constraints allow to define invariants that have to be fulfilled by a valid mapping. They are aggregated in the MappingConstraint element as introduced in chapter 5 and depicted Figure 5.1. This chapter describes which mapping constraints can be described in the System Constraint Description. The description of this meta-class can be found in the following table:

Class	***MappingConstraint*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	Different constraints that may be used to limit the mapping of SW components to applicable ECUs, Partitions or Cores depending on the mappingScope attribute.			
Base	*ARObject*			
Subclasses	ComponentClustering, ComponentSeparation			
Aggregated by	SystemMapping.mappingConstraint			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
introduction	DocumentationBlock	0..1	aggr	This represents introductory documentation about the mapping constraint.

Table 5.8: MappingConstraint

The two constraints (ComponentClustering and ComponentSeparation) shown in Figure 5.5 express the restrictions that Software Components impose on each other when performing the mapping onto the ECUs, Cores or Partitions. In fact, before the mapping process begins, it can be useful to impose the allocation of a predefined set of SW components onto the same ECU, especially if such a set is tightly linked from a functional point of view. In the same way, two critical SW components, performing some kind of redundancy, may be not suitable to run both on the same ECU. Thus, we call these two kinds of mapping constraints, respectively, ComponentClustering and ComponentSeparation.

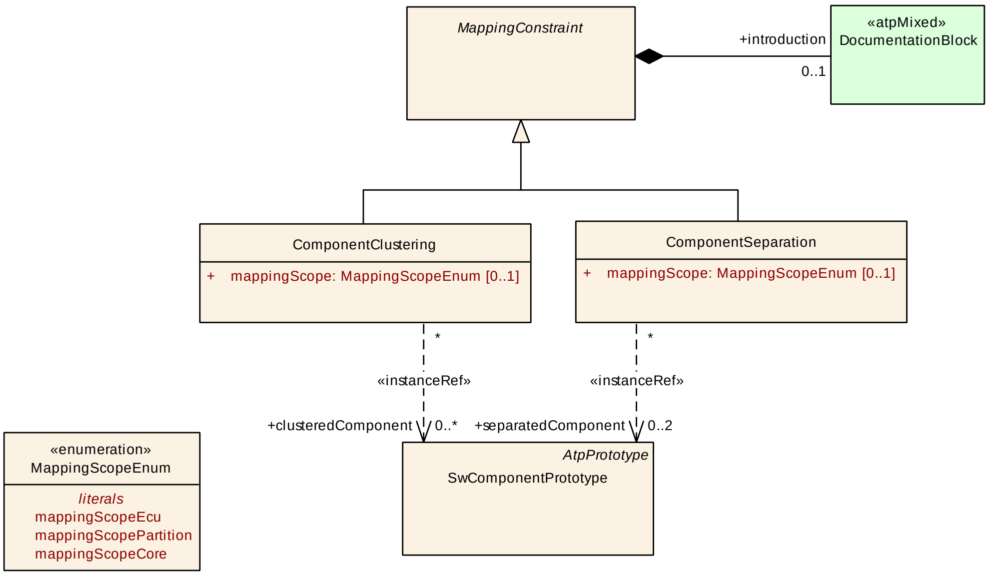

Figure 5.5: Details on ComponentClustering and ComponentSeparation (SwcClustering)

5.1.4.1 ComponentClustering

[TPS_SYST_01024] Component Clustering

Upstream requirements: RS_SYST_00008

⌈The `ComponentClustering` constraint (also, *clustering*) is to be used for expressing that a certain set of SW components (atomic or not) shall be mapped (allocated) onto the same ECU, Core, Partition depending on the defined `mappingScope` attribute.⌋

This is some kind of "execute together on same ECU" constraint.

The semantic of the clustering constraint is straightforward if all referenced SW components are atomic. Otherwise, it shall be interpreted as follows:

[TPS_SYST_01025] Clustering of Compositions

Upstream requirements: RS_SYST_00008

⌈All of the atomic SW components making up the composition shall be mapped onto the same ECU, Core, Partition depending on the defined `mappingScope` attribute together with all other SW components (atomic or not) referenced by the constraint.⌋

This also means that a *clustering* constraint can also refer to only a single composition.

A *clustering* constraint is part of a `MappingConstraint` element and it shall refer to one or more `SwComponentPrototype` elements, representing the instances of the SW component(s) that shall be mapped together.

Class	ComponentClustering			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	Constraint that forces the mapping of all referenced SW component instances to the same ECU, Core, Partition depending on the defined mappingScope attribute. If mappingScope is not specified then mappingScopeEcu shall be assumed.			
Base	*ARObject*, *MappingConstraint*			
Aggregated by	SystemMapping.mappingConstraint			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
clustered Component	SwComponent Prototype	*	iref	Reference to the components that have to be mapped together. **InstanceRef implemented by:** ComponentInSystem InstanceRef
mappingScope	MappingScopeEnum	0..1	attr	This attribute indicates whether the ComponentClustering mapping constraint applies to different ECUs, partitions or cores. If this attribute is not specified then mappingScope Ecu shall be assumed.

Table 5.9: ComponentClustering

mappingScopeEcu	The mapping constraint applies to different Ecus. **Tags:** atp.EnumerationLiteralIndex=1
mappingScope Partition	The mapping constraint applies to different Partitions. **Tags:** atp.EnumerationLiteralIndex=2

Table 5.10: MappingScopeEnum

[constr_5491] Existence of `ComponentClustering.clusteredComponent`

Imposition time: `IT_SysDesc`

⌈For each `ComponentClustering`, at least one reference to `SwComponentPrototype` in the role `clusteredComponent` shall exist.⌋

5.1.4.2 ComponentSeparation

[TPS_SYST_01045] Component Seperation

Upstream requirements: RS_SYST_00009

⌈The `ComponentSeparation` constraint (also, *separation*) is to be used for expressing that two SW components (atomic or not) shall not be mapped (allocated) onto the same ECU, Core, Partition depending on the defined `mappingScope` attribute.⌋

This is some kind of “do not execute together on same ECU” constraint.

The semantic of the separation constraint is straightforward if one or both SW components are atomic. Otherwise, it shall be interpreted as follows:

[TPS_SYST_01026] Separation of Compositions

Upstream requirements: RS_SYST_00009

⌈Any of the atomic SW components making up the first composition, shall not be mapped onto the same ECU, Core, Partition depending on the defined mappingScope attribute with any atomic SW component from the second composition.⌋

As a consequence, and to preserve consistency, an atomic SW component instance cannot be part of two compositions concerned by the same separation constraint, i.e. the two compositions have to be disjoint with regards to component instances[1].

A *separation* constraint is part of a MappingConstraint element and it shall refer to two SwComponentPrototype elements, representing the two SW component instances that shall not be allocated together.

Class	**ComponentSeparation**			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	Constraint that forces the two referenced SW components (called A and B in the following) not to be mapped to the same ECU, Core, Partition depending on the defined mappingScope attribute. If mapping Scope is not specified then mappingScopeEcu shall be assumed. If a SW component (e.g. A) is a composition, none of the atomic SW components making up the A composition shall be mapped together with any of the atomic SW components making up the B composition. Furthermore, A and B shall be disjoint.			
Base	*ARObject*, *MappingConstraint*			
Aggregated by	SystemMapping.mappingConstraint			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
mappingScope	MappingScopeEnum	0..1	attr	This attribute indicates whether the Component Separation mapping constraint applies to different ECUs, partitions or cores. If this attribute is not specified then mappingScopeEcu shall be assumed.
separated Component	SwComponent Prototype	0..2	iref	The two components that have to be mapped to different ECUs **InstanceRef implemented by:** ComponentInSystem InstanceRef

Table 5.11: ComponentSeparation

[1]The only case where a component instance could be in both sets is if the ComponentSeparation refers to two elements where one of them is a substructure of the other. Consider the case that Atomic SW Component A is aggregated by composition B, which in turn is aggregated by composition C. Then instance A is both in B and C. It is not a good idea to formulate a separation constraint stating that B and C should not be on the same ECU.

[constr_3004] Clustering and separation shall be exclusive

Imposition time: IT_SysDesc

⌈Clustering and separation shall be exclusive, i.e. it SHALL NOT be possible that two SwComponentPrototypes A and B are associated both by a ComponentClustering and by a ComponentSeparation at the same time.⌋

Please note that it is possible that one SwComponentPrototype is referenced by both the ComponentClustering and ComponentSeparation, so the [constr_3004] is about the pair of SwComponentPrototypes and not about a single one.

For example it shall be possible to associate ComponentClustering and ComponentSeparation at the same time, e.g.

- A and B have a ComponentClustering_1 association
- B and C have a ComponentSeparation_2 association
- A and D have a ComponentSeparation_3 association

In this setup A and B are associated by a ComponentClustering and by a ComponentSeparation without violating [constr_3004].

[constr_5492] Existence of ComponentSeparation.separatedComponent

Imposition time: IT_SysDesc

⌈For each ComponentSeparation always two references to SwComponentPrototypes in the role separatedComponent shall exist.⌋

5.1.5 J1939 Controller Application Mapping

J1939 is not restricted to mere communication protocols. It also specifies the communication of software functions (a.k.a. J1939 Controller Applications) and thus has a very dedicated view on the software of an automotive ECU. The approach taken by J1939 with respect to software is very similar to the way AUTOSAR specifies software-components.

However, J1939 uses a different terminology and associates such a software-component with a predefined function. In addition, every function in J1939 has a standardized id. This function id is distributed by the Controller Application to the network as part of the so-called "name" which is a unique identifier representing a Controller Application within the J1939 network management.

Controller Applications, to some extent, fulfill the role of a "virtual ECU" since they are visible as independent entities on a J1939 network. In terms of AUTOSAR modeling, the role of a "virtual ECU" for J1939 Controller Applications is fulfilled by the meta-class J1939NmNode.

In order to make use of the AUTOSAR modeling approach for J1939 it is very helpful to associate a standardized function id with a software-component during an early phase of a development project. This function id shall later be mapped to a J1939NmNode with the identical J1939NmNode.nodeName.function.

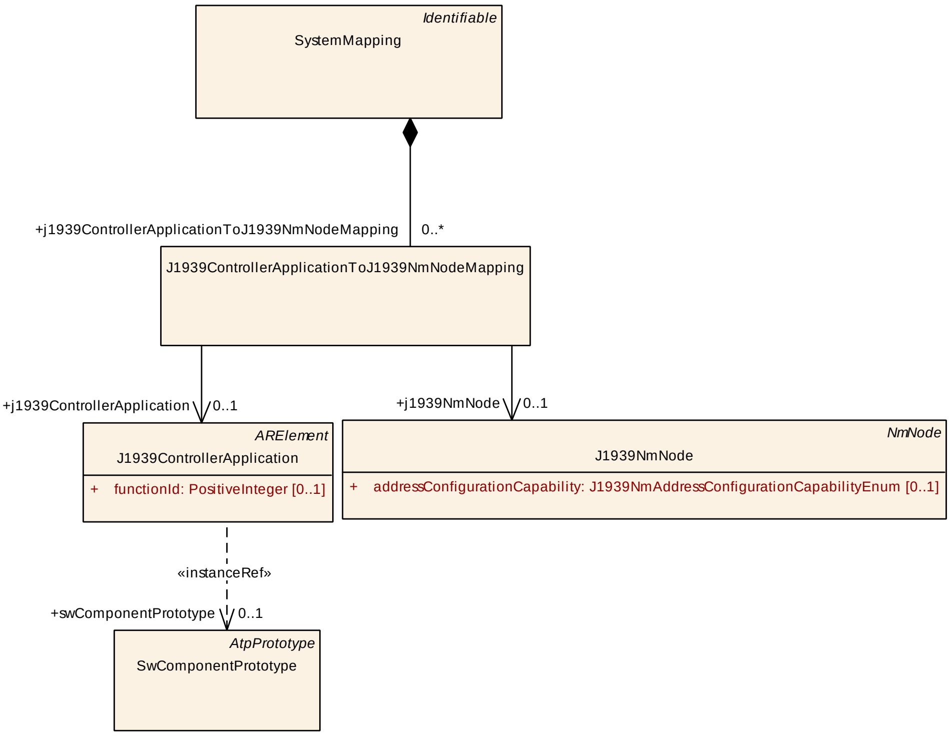

Figure 5.6: J1939 Controller Application to J1939NmNode Mapping

Class	**J1939ControllerApplicationToJ1939NmNodeMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::SWmapping			
Note	This meta-class represents the ability to map a J1939ControllerApplication to a J1939NmNode. Note that this is similar but not identical to the mapping of SwComponentPrototypes to EcuInstances; for J1939 the semantics of an EcuInstance itself is basically replaced by a J1939NmNode.

5.1.6 Affinity Constraints

This chapter defines the possibility to describe constraints for the mapping of RTEEvents to OsTasks. The meta-class OsTaskProxy is used in the System Description to represent an OsTask that is defined in the Ecu Configuration of the OS.

The mapping of an RTEEvent to an OsTaskProxy can be defined in the context of the System (see chapter 5.1.6.2) or in the context of a Software Composition (see chapter 5.1.6.1).

Class	***RTEEvent*** (abstract)

5.2 Data Mapping

The data mapping description may either be mapping of client server communication or sender receiver communication (see Figure 5.10). It is used to map `VariableDataPrototype`s or `ClientServerOperation`s of SW Component Ports to `SystemSignal`s.

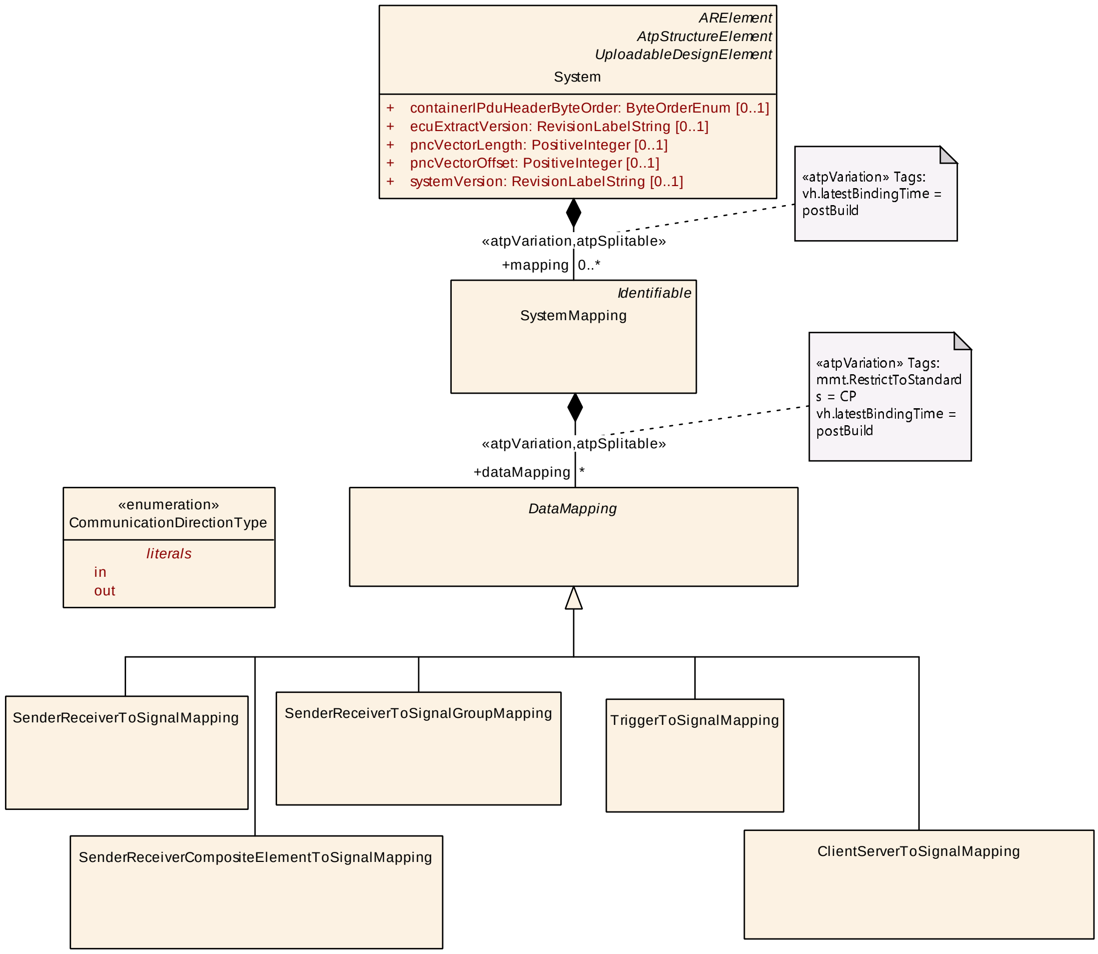

Figure 5.10: Overview: Data Mapping Description (DataMappingOverview)

[TPS_SYST_01030] Representation of `VariableDataPrototype`s and `ClientServerOperation`s in System Description

Upstream requirements: RS_SYST_00025

⌈`SystemSignal`s represent `VariableDataPrototype`s and `ClientServerOperation`s in the communication description.⌋

[constr_5055] `DataMapping` of elements of `PRPortPrototype`s is not supported

Imposition time: `IT_EcuExt`

⌈A `DataMapping` shall not map elements of `PRPortPrototype`s to `SystemSignal`s⌋

In other words the usage of `PRPortPrototype`s for inter-Ecu communication is not supported by AUTOSAR.

[constr_5266] VariableDataPrototype of NvDataInterface shall not be mapped to a SystemSignal

Imposition time: IT_EcuExt

⌈A VariableDataPrototype that is aggregated by a NvDataInterface shall not be referenced by

- SenderReceiverToSignalGroupMapping in the role dataElement and
- SenderReceiverToSignalMapping in the role dataElement.

⌋

[constr_5267] VariableDataPrototype of NvDataInterface shall not be mapped to a SystemSignal via a delegation to a PortPrototype with a SenderReceiverInterface

Imposition time: IT_EcuExt

⌈If a VariableDataPrototype that is aggregated by a

- SenderReceiverInterface and that SenderReceiverInterface is referenced by a PortPrototype of a Composition and
- that PortPrototype is connected by a delegation connector with an inner PortPrototype of a NvBlockSwComponentType and
- that PortPrototype is typed by a NvDataInterface

then this PortPrototype shall not be referenced by:

- SenderReceiverToSignalGroupMapping in the role dataElement and
- SenderReceiverToSignalMapping in the role dataElement.

⌋

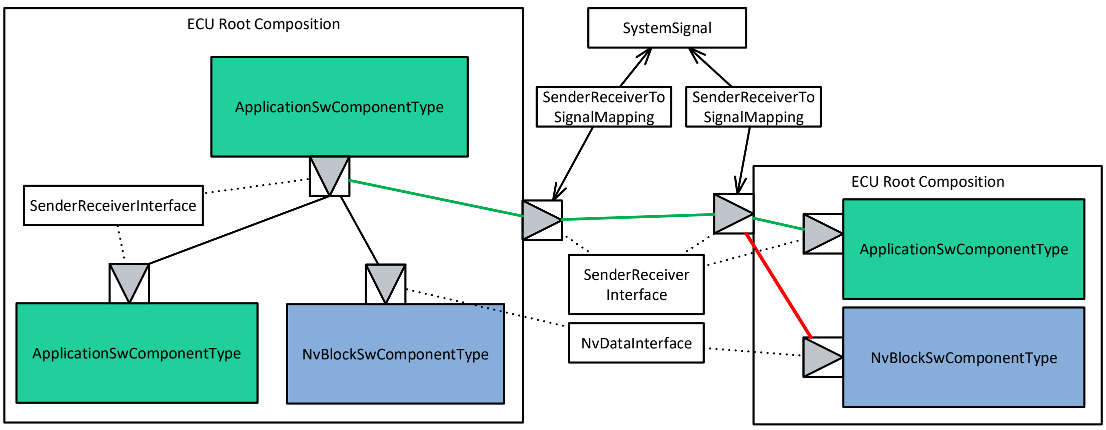

Figure 5.11: Mapping scenario that is forbidden by constr_5267

The figure 5.11 shows the scenario that is forbidden by [constr_5267]. The Port of the NvBlockSwComponentType is delegated to the Ecu Root Composition by the red connector. The VariableDataPrototype of the outer Port that is typed by a SenderReceiverInterface is mapped to a SystemSignal for communication over the network.

A scenario that would be allowed is shown in figure 5.12. Here the NvBlockSwComponentType is connected to an ApplicationSwComponentType in the same Ecu Root Composition. Data that is communicated over the network is contained in an additional Port of the ApplicationSwComponentType that is delegated to the outer Port of the Composition for the definition of the DataMapping. In this scenario [constr_5266] and [constr_5267] are not violated.

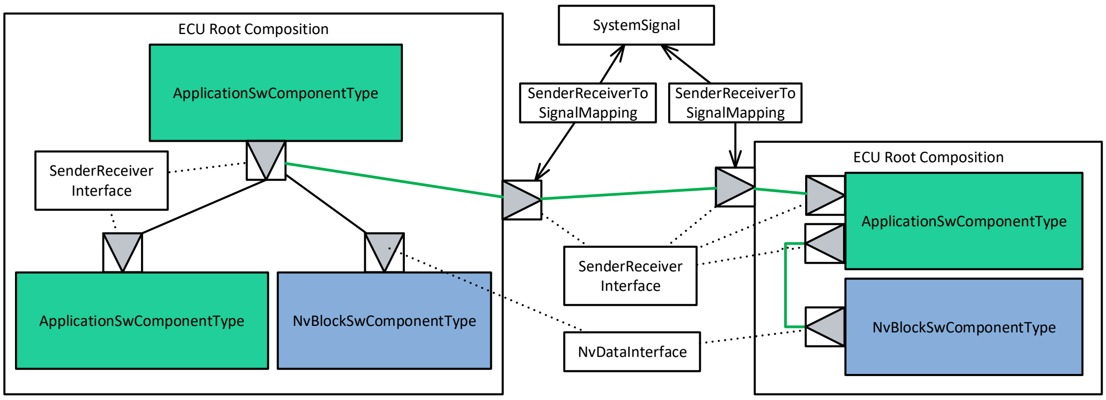

Figure 5.12: Supported mapping scenario

[constr_4000] Local communication of mode switches

Imposition time: IT_EcuExt

⌈Ports with ModeSwitchInterfaces cannot be connected across ECU boundaries.⌋

In other words a DataMapping for ModeDeclarationGroupPrototypes is not supported.

[TPS_SYST_01032] Independence of SystemSignals from CommunicationClusters ⌈The SystemSignals can be defined independently of CommunicationClusters.⌋

This chapter describes how the VariableDataPrototypes and ClientServerOperations are mapped onto SystemSignals. The Communication chapter (6) describes how the SystemSignals are mapped into Pdus and Frames, implementing the actual inter-ECU communication.

Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	The system signal represents the communication system's view of data exchanged between SW components which reside on different ECUs. The system signals allow to represent this communication in a flattened structure, with exactly one system signal defined for each data element prototype sent and received by connected SW component instances. **Tags:** atp.recommendedPackage=SystemSignals			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
dynamicLength	Boolean	0..1	attr	The length of dynamic length signals is variable in run-time. Only a maximum length of such a signal is specified in the configuration (attribute length in ISignal element).
physicalProps	SwDataDefProps	0..1	aggr	Specification of the physical representation. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=physicalProps

Table 5.23: SystemSignal

A `SystemSignal` is used to represent `VariableDataPrototype`s for network transport.

The motivation for `SystemSignal`s is to represent (physical) data which is exchanged between ECUs as a design element. The `SystemSignal` gives data an identity and allows to refer to that information from different context.

`SystemSignal`s are part of the communication matrix and are used as the binding blocks between the Software Component data access and the communication stack infrastructure.

The `SystemSignal`s are mapped to the `PortPrototype`s of Software Components, and the `SystemSignal`s are referenced by `ISignal`s of the communication stack (see Section 6.2). `ISignal`s are placed in `ISignalIPdu`s and `Pdu`s are transported on networks.

The creation of the relation between elements of a `PortPrototype` and corresponding `SystemSignal`s has value on its own, both as the bus-independent communication matrix and as a milestone in the workflow towards further downstream processing, where the focus changes to bus-specific descriptions. In other words, if you throw away the bus specific description, you don't have to start from scratch, thanks to the existence of a stable bus-independent baseline from which the bus-specific part could be derived again.

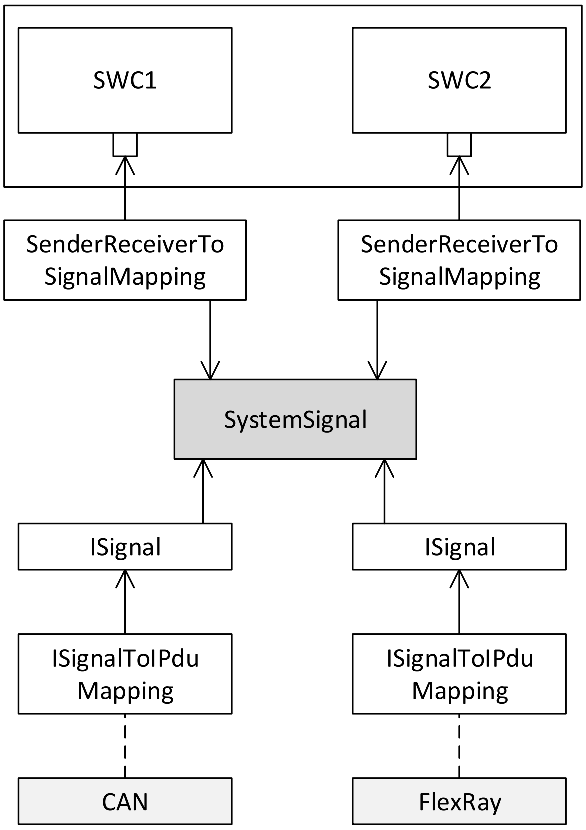

Figure 5.13: Example for a SystemSignal and a DataMapping

[TPS_SYST_01144] Physical properties of a `SystemSignal` ⌈With the aggregation of `SwDataDefProps` in the role `physicalProps` the physical properties of the `SystemSignal` can be specified.⌋

[TPS_SYST_05000] System Description doesn't use a complete Software Component Description

Upstream requirements: RS_SYST_00001

⌈If the System Description doesn't use a complete Software Component Description (VFB View) the data mapping of `VariableDataPrototype`s or `ArgumentDataPrototype`s owned by `ClientServerOperation`s on `SystemSignal`s does not need to be defined. This supports the inclusion of legacy signals.⌋

The data mapping may be defined in various ways to achieve the same behavior. The examples shown in figures 5.14, figure 5.15, and figure 5.16. All data mappings have the goal of mapping the data produced at a software component PortPrototype to two sets of ISignals. This use-case is typically applied when data produced by the software component shall be transported on two different networks. One network may be able to transport all of the produced data, while the other network may have a reduced bandwidth, and thus only a subset of the produced data is actually transmitted on that network.

In the example where *RootComp X* is involved (figure 5.14) the data of the PortPrototype is mapped to one SystemSignalGroup. This SystemSignalGroup uses one set of SystemSignals to define the transported data. Then two sets of ISignalGroups with dedicated ISignals are defined.

One aspect of the data mapping as defined for *RootComp X* is that there exists only one SystemSignalGroup. If the ISignalGroups are transported on different networks, then also the SystemSignalGroup is used on both networks. This leads to the situation that on the network where *ISignalGroup2* is used the corresponding SystemSignalGroup has the SystemSignal *b*, although on that network *b* is not transported.

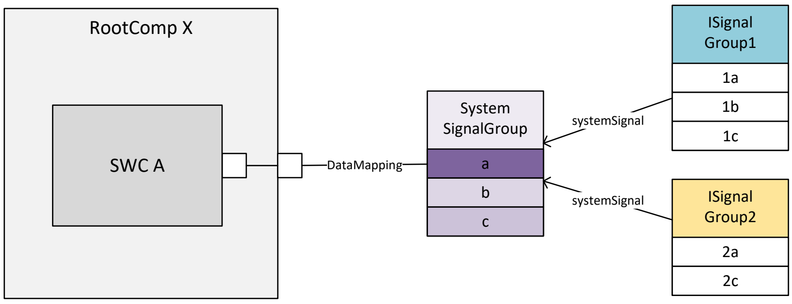

Figure 5.14: Example of possible data mapping definition

That is one motivation why the setup of *RootComp Y* (figure 5.15) may be favoured, as in this example two SystemSignalGroups are used. Note that some of the SystemSignals are actually shared for the definition of both SystemSignalGroups (i.e. SystemSignals *a* and *c* are used by both SystemSignalGroups).

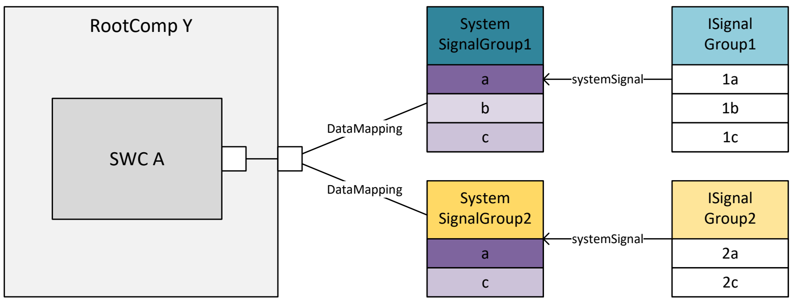

Figure 5.15: Example of possible data mapping definition

Another alternative modeling is shown in the illustration for *RootComp Z* (figure 5.16), where a delegation of the data is already modeled at the RootSwCompositionPrototype. The data mappings are applied in this example individually per delegated PortPrototype to individual SystemSignalGroups with again shared SystemSignals.

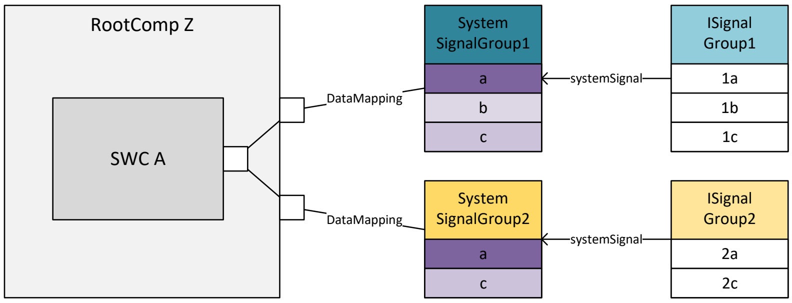

Figure 5.16: Example of possible data mapping definition

Which of the illustrated approaches is use depends on the modeling and export strategy of the system description designer. The RTE behavior shall be the same for all three modeling variants.

The effective behavior of the RTE for the possible data mappings illustrated in the previous figures is shown in figure 5.17.

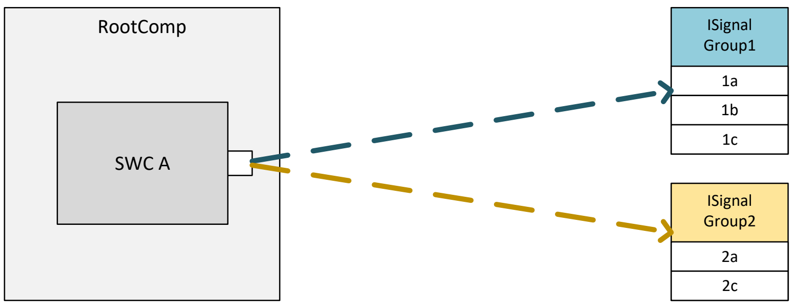

Figure 5.17: Example of resulting effective RTE behavior

[constr_3501] Role of SystemSignal in 1:n communication

Imposition time: IT_EcuExt

⌈In case of 1:n communication the VariableDataPrototype in the PPortPrototype of the SwComponentPrototype shall be mapped to only one SystemSignal.⌋

Note that [constr_3501] is also fulfilled by the modeling approaches illustrated in figures 5.15 and 5.16 where several SystemSignalGroups share some SystemSignals. Such a setup is shown in figure 5.18 from a detailed model perspective.

SystemSignal b is only used in one SystemSignalGroup, thus only one data mapping is pointing to *SystemSignal b*.

But *SystemSignal a* and *SystemSignal c* are used in both SystemSignalGroups, thus there are two sets of data mappings defined. But each of the data mappings refer to same pair of *RecordElement* and *SystemSignal*, thus [constr_3501] is still fulfilled.

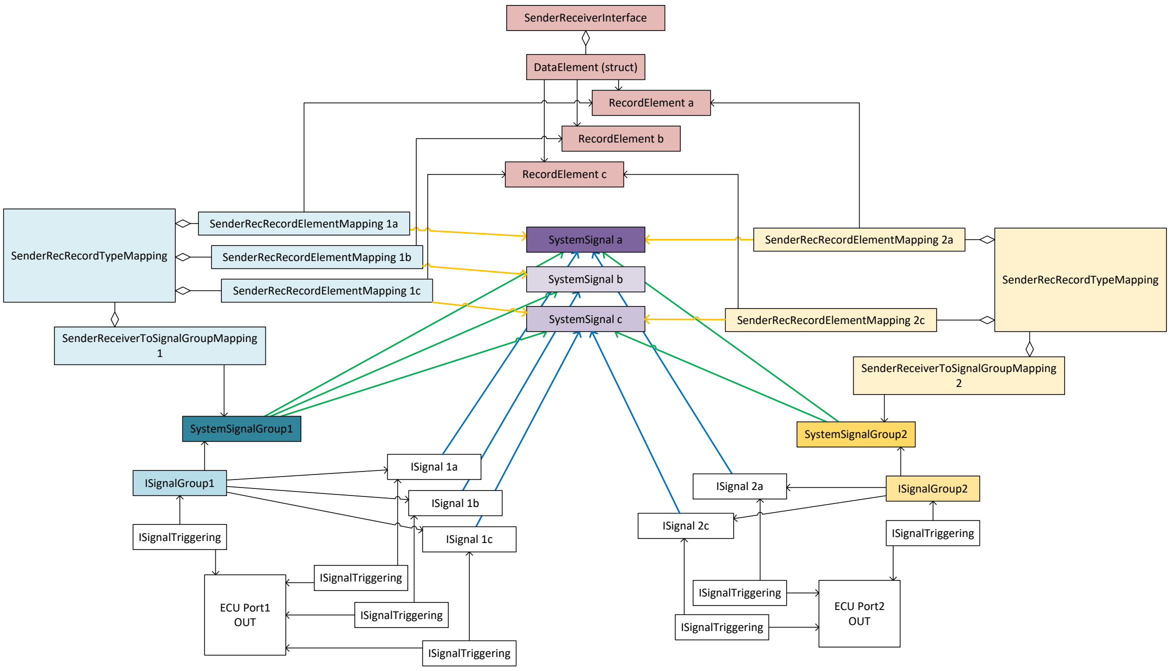

Figure 5.18: Detailed model of several data mappings

In case of figure 5.16 the delegation connectors need to be resolved, which results again in two data mappings with partial identical mapping pairs.

[constr_3086] Role of SystemSignal in n:1 sender-receiver communication

Imposition time: IT_EcuExt

⌈In case of n:1 communications

- if DataTransformation is used each sender shall be mapped to the same SystemSignal
- if DataTransformation is not used each sender shall be mapped
  - to the same SystemSignal in case of a primitive DataType on the sender side,
  - to the same SystemSignalGroup in case of a composite DataType on the sender side.

⌋

[constr_5117] Client-Server communication over Ethernet

Imposition time: IT_SysDesc

⌈A SystemSignal that is referenced by a ClientServerToSignalMapping in the role callSignal or returnSignal shall only be referenced by an ISignal that in turn is referenced by an ISignalTriggering aggregated by an EthernetPhysicalChannel.⌋

In other words, the client-server communication is only supported by AUTOSAR on the Ethernet communication channel.

[TPS_SYST_02150] Role of SystemSignal in inter-ECU client server communication over Ethernet with clients located on different ECUs ⌈In case of a n:1 inter-ECU client server communication over Ethernet with clients located on different ECUs exactly one SystemSignal per communication direction shall be used to define the client server interaction between the server and all clients since the relationship between the call and return is achieved by means of meta data items attached to the Pdus by the Socket Adapter.⌋

[TPS_SYST_02151] MetaData support required for inter-ECU client server communication over Ethernet with clients located on different ECUs ⌈The modeling of client server interaction over Ethernet with clients located on different ECUs requires the support of COM Stack MetaData. The relationship between the call and return is achieved by means of meta data items attached to the Pdus by the Socket Adapter.⌋

[TPS_SYST_01087] Role of SystemSignal in inter-ECU client server communication with clients located on the same ECU ⌈In case of n:1 inter-ECU client server communication it is allowed to use the same SystemSignal for several clients on the same Ecu, if the client identifier is used to distinguish the different clients.⌋

[constr_3112] Invalidation support for partial mapping of a data element typed by composite data type

Imposition time: IT_EcuExt

⌈If a VariableDataPrototype with a composite data type in a PPortPrototype is mapped to a SystemSignalGroup and only a subset of elements of the composite data type that are primitives is mapped to separate SystemSignals of the SystemSignalGroup then at least one mapped primitive shall have an invalidValue defined.⌋

[constr_3074] No TransmissionAcknowledgementRequest for multiple senders

Imposition time: IT_EcuExt

⌈If more than one SenderComSpec exist (in different PortPrototypes on atomic level) that refer to data elements effectively mapped to the same SystemSignal it is not allowed that any SenderComSpec aggregates transmissionAcknowledge.⌋

Please note that the term “effectively mapped” refers to the fact that the DataMapping can refer to a dataElement in a "delegation" PortPrototype on the surface of a rootSoftwareComposition of an Ecu Extract OR to PortPrototypes inside the rootSoftwareComposition. Both ways shall be considered.

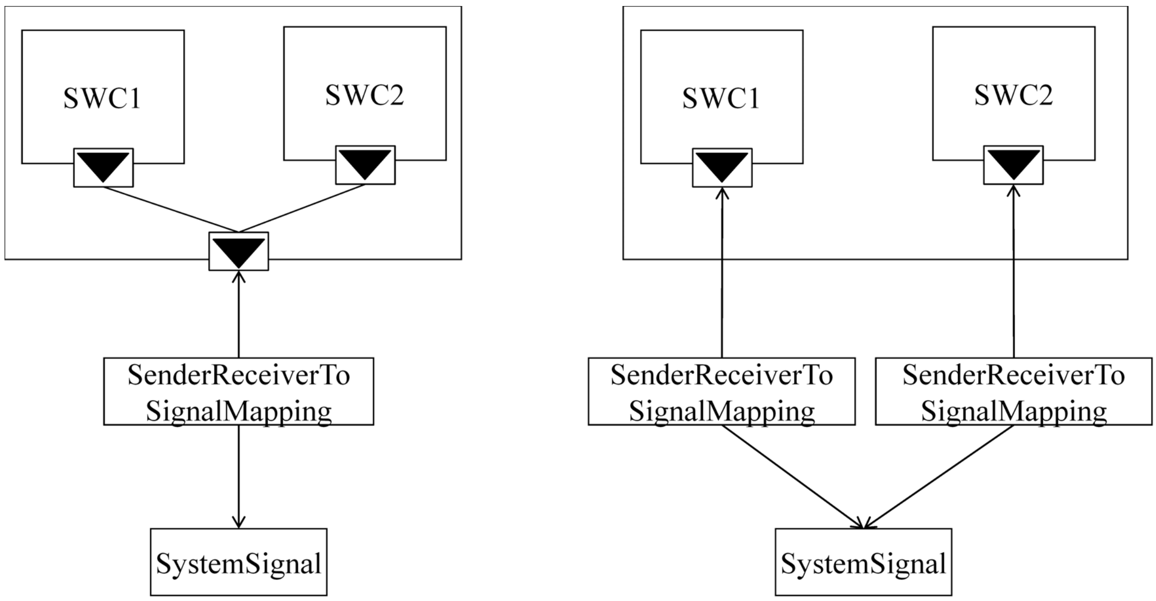

Figure 5.19: Example for data elements that are effectively mapped to the same System-Signal

The different kinds of data mapping are described in the following sections in detail.

Please note that the usage of ImplementationDataTypes within an AnyInstanceRef is described in detail in [1].

5.2.1 Mapping of Variable Data Prototypes on System Signals

This section describes how VariableDataPrototypes are mapped onto SystemSignals. For a detailed description of the interconnection of software components refer to [4].

It is the task of system configuration to map VariableDataPrototype, ClientServerOperation, or Trigger contained in PortPrototypes referenced by the SwConnector onto a SystemSignal.

[TPS_SYST_01033] DataMapping and SwConnector ⌈For the purpose of creating DataMappings PortPrototypes may or may not be connected by SwConnectors.⌋

The same SystemSignal may satisfy more than one SwConnector (1:n communication), and one SwConnector may be implemented by several SystemSignals (e.g. one per VariableDataPrototype in the PortInterface being connected), so there is no 1:1 mapping between SwConnectors and SystemSignals.

In the following sections, each reference to a VariableDataPrototype, ArgumentDataPrototype, or Trigger is of type AtpInstanceRef [1]. This means it not only references the actual VariableDataPrototype, but additionally contains contextual references to the PortPrototype and the hierarchy of SwComponentPrototypes forming the individual instance context of the VariableDataPrototype.

In a complete System with category SYSTEM_DESCRIPTION, it is sufficient to refer to the VariableDataPrototype in the PPortPrototype or the RPortPrototype to define the mapping of the communication between a provider and its receivers.

This is possible since the connectors implicitly define which RPortPrototype are connected to which PPortPrototype. In case the System with category SYSTEM_DESCRIPTION does not use a complete Software Component Description (VFB View) the data mapping needs not to be defined. This supports the inclusion of legacy signals.

[TPS_SYST_01137] Several DataMappings may be defined for the same SystemSignal ⌈For a SystemSignal which is

- part in several SystemSignalGroups
- part in at least one SystemSignalGroup and at the same time is transmitted additionally as standalone SystemSignal
- used in N:1 sender-receiver communication where the same SystemSignal is mapped to compatible VariableDataPrototypes with DataMappings on different SwComponentPrototypes. Please note that in this case [constr_9330] applies.

- used in a ClientServer communication where the same SystemSignal is used for a compatible ClientServerOperation in DataMappings on the different clients

several DataMappings may be defined.⌋

[constr_9330] Derivation of network representation in case that several DataMappings are defined that map the same SystemSignal to different VariableDataPrototypes

Imposition time: IT_SysDesc

⌈If several DataMappings are defined that map the same SystemSignal to different VariableDataPrototypes then

- all ISignals that reference this SystemSignal shall define networkRepresentationProps or
- if networkRepresentationProps are not specified on the ISignal level (and are therefore derived from the ImplementationDataType) then the different DataMappings shall reference VariableDataPrototypes that in turn reference the identical ImplementationDataType.

⌋

Please note that [constr_9330] was introduced to forbid cases in which a serializing transformer will get contradicting requirements regarding the network representation. As an alternative the scenario sketched on the left side in Figure 5.19 may be used in which only one data mapping on the composition is defined.

As the SystemSignal represents a specific information this information may appear in different delivery units, but it is still the same information.

One example could be the tire pressure sensor value. At first each wheel's tire pressure value exists alone, as they are captured at each wheel individually. So there are 4 SystemSignals defined for a 4 wheel vehicle. If now some Software Component receives all 4 tire pressure values and puts them inside a SystemSignalGroup for consistent handling, then those 4 tire pressure values are still represented by the same 4 SystemSignals. Thus each individual tire pressure SystemSignal may appear as stand-alone as well as part of a SystemSignalGroup.

[TPS_SYST_01050] SystemSignal in the System Extract and ECU Extract ⌈In the System with category SYSTEM_EXTRACT or ECU_EXTRACT the missing DataMappings on the complementary Sender/Receiver side needs to be supplemented.⌋

In the System with category SYSTEM_EXTRACT or ECU_EXTRACT, where only the relevant parts of the rootSoftwareComposition are defined, it is necessary to utilize the information from the complementary PortPrototype if the corresponding

PortPrototype is located on another ECU and thus is not part of the extract. This is described in more detail in chapter 13.2 and chapter 14.2.3.

Therefore in a System with category ECU_EXTRACT the DataMappings are provided on both, PPortPrototypes and RPortPrototypes.

[TPS_SYST_01034] Data Mappings can be applied to compositions and atomic software components ⌈DataMappings can be applied to CompositionSwComponentTypes and on AtomicSwComponentTypes in a System of category ECU_EXTRACT.⌋

Please note that for a System of category ECU_EXTRACT [constr_5328] applies.

[TPS_SYST_01035] Transformation of Data Mappings during flattening ⌈During the creation of the System with category ECU_EXTRACT (flattening) each existing DataMapping that is referencing a PortPrototype of a SwComponentType that is not directly referenced by the RootSwCompositionPrototype in the role softwareComposition shall be transformed to a DataMapping that directly refers by means of a DataPrototypeInSystemInstanceRef to a PortPrototype of the CompositionSwComponentType that is referenced by the RootSwCompositionPrototype in the role softwareComposition.⌋

In other words in the System with category ECU_EXTRACT only DataMappings defined on the outerPorts of the RootSwCompositionPrototype are allowed to exist.

[TPS_SYST_01036] No additional Data Mappings in composition substructure ⌈When a CompositionSwComponentType is refined by a supplier the already existing DataMappings that refer to the CompositionSwComponentType shall not be copied to the internal substructure.⌋

Suppliers who add substructure to a CompositionSwComponentType by adding SwComponentPrototypes and SwConnectors shall respect the predefined DataMappings on the CompositionSwComponentType.

The OEM/Supplier Collaboration Scenario is described in chapter 13.1.

[TPS_SYST_05034] DataMapping of ImplementationDataType of category UNION, DATA_REFERENCE, or FUNCTION_REFERENCE ⌈SenderReceiverInterface.dataElement that is typed by an ImplementationDataType of category UNION, DATA_REFERENCE, or FUNCTION_REFERENCE is not allowed to be mapped by a DataMapping.⌋

Please note that for unions there is [constr_1441] and [constr_1607] that are restricting such a modeling.

5.2.1.1 Mapping of Variable Data Prototypes with primitive datatypes on System Signals (Sender-Receiver Communication)

This section describes the relation between the VariableDataPrototype with primitive datatypes and the SystemSignal (see Figure 5.20).

[TPS_SYST_02082] SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category VALUE or BOOLEAN and a DataTypeMap exists ⌈If a SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category VALUE or BOOLEAN and a DataTypeMap exists that points to the ApplicationPrimitiveDataType and an ImplementationDataType of category VALUE or TYPE_REFERENCE that eventually references (via the SwDataDefProps.implementationDataType) an ImplementationDataType of category VALUE, then this SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02083] SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category STRING and a DataTypeMap exists ⌈If a SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category STRING and a DataTypeMap exists that points to the ApplicationPrimitiveDataType and an ImplementationDataType of category ARRAY or TYPE_REFERENCE that eventually references (via the SwDataDefProps.implementationDataType) an ImplementationDataType of category ARRAY with a subElement that either

- represents the platform type uint8 or
- references a SwBaseType with a SwBaseType.baseTypeDefinition.baseTypeSize set to the value 8 and the SwBaseType.baseTypeDefinition.baseTypeEncoding set to NONE,

then this SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02084] SenderReceiverInterface.dataElement is typed by an ApplicationArrayDataType and a DataTypeMap exists ⌈If a SenderReceiverInterface.dataElement is typed by an ApplicationArrayDataType and a DataTypeMap exists that points to the ApplicationArrayDataType and an ImplementationDataType of category ARRAY or TYPE_REFERENCE that eventually references (via the SwDataDefProps.implementationDataType) an ImplementationDataType of category ARRAY with a subElement that either

- represents the platform type uint8 or

- references a SwBaseType with a SwBaseType.baseTypeDefinition.baseTypeSize set to the value 8 and the SwBaseType.baseTypeDefinition.baseTypeEncoding set to NONE,

then this SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02085] SenderReceiverInterface.dataElement is typed by an ImplementationDataType of category ARRAY ⌈If a SenderReceiverInterface.dataElement is typed by an ImplementationDataType of category ARRAY with a subElement that either

- represents the platform type uint8 or
- references a SwBaseType with a SwBaseType.baseTypeDefinition.baseTypeSize set to the value 8 and the SwBaseType.baseTypeDefinition.baseTypeEncoding set to NONE,

then this SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02086] SenderReceiverInterface.dataElement is typed by an ImplementationDataType of category VALUE or TYPE_REFERENCE ⌈If a SenderReceiverInterface.dataElement is typed by an ImplementationDataType of category VALUE or TYPE_REFERENCE that eventually references (via the SwDataDefProps.implementationDataType) an ImplementationDataType of category VALUE then this SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02087] SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category BOOLEAN and no DataTypeMap exists ⌈The SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02088] SenderReceiverInterface.dataElement is typed by an ApplicationArrayDataType and no DataTypeMap exists ⌈If a SenderReceiverInterface.dataElement is typed by an ApplicationArrayDataType and no DataTypeMap exists and the ApplicationArrayDataType fulfills the following conditions:

- ApplicationPrimitiveDataType.swDataDefProps.dataConstr exists and refers to a PhysConstrs.
- ApplicationPrimitiveDataType.swDataDefProps.compuMethod exists and refers to a CompuMethod of category TEXTTABLE and CompuMethod.compuPhysToInternal exists.

- Application of ApplicationPrimitiveDataType.swDataDefProps.compuMethod to ApplicationPrimitiveDataType.swDataDefProps.dataConstr yields a numerical range in [0 .. 255]

then the SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02089] SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category STRING and no DataTypeMap exists ⌈If a SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category STRING and no DataTypeMap exists and the ApplicationPrimitiveDataType fulfills the following conditions:

- ApplicationPrimitiveDataType.swDataDefProps.swRecordLayout exists and values of SwRecordLayout.swRecordLayoutGroup.swRecordLayoutGroupFrom and SwRecordLayout.swRecordLayoutGroup.swRecordLayoutGroupTo are both set to 1.
- AApplicationPrimitiveDataType.swDataDefProps.swTextProps exists and refers to an SwBaseType where the SwBaseType.baseTypeDefinition.baseTypeEncoding is set to NONE and the value of SwBaseType.baseTypeDefinition.baseTypeSize is set to 8.

then the SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_02090] SenderReceiverInterface.dataElement is typed by an ApplicationPrimitiveDataType of category VALUE and no DataTypeMap exists ⌈There is no clear indication that the SenderReceiverInterface.dataElement is a candidate for a primitive Data Mapping.⌋

[TPS_SYST_01037] primitive Data Mapping of UINT8-Arrays ⌈The primitive Data Mapping may also be used for the Data Mapping of UINT8-Arrays. This supports an optimized definition of the Data Mapping.⌋

In other words it is allowed to map an array VariableDataPrototype consisting of UINT8 elements to exactly one SystemSignal in the context of one SenderReceiverToSignalMapping. A UINT8 element may be a String or an array that contains array elements of Integer type with range 0..255.

Background: In the ECU Configuration of the AUTOSAR COM module such a SystemSignal will be mapped to a COM Signal with the ComSignalType UINT8_N.

[TPS_SYST_02279] SenderReceiverInterface.dataElement is typed by a “new-world” variable-size ApplicationArrayDataType and a DataTypeMap exists ⌈A SenderReceiverInterface.dataElement is a candidate for a primitive

SenderReceiverToSignalMapping to a single SystemSignal if all following conditions are fulfilled:

- a SenderReceiverInterface.dataElement is typed by an ApplicationArrayDataType that fulfills the conditions of a “new-world” dynamic-size array data type according to [TPS_SWCT_01644] (see definition in Software Component Template [4])
- the ApplicationArrayDataType has the dynamicArraySizeProfile = VSA_LINEAR
- a DataTypeMap exists that points to both the ApplicationArrayDataType and an ImplementationDataType that fulfills the conditions of a “new-world” dynamic size array data type according to [TPS_SWCT_01645] (see definition in Software Component Template [4]) and is of category STRUCTURE
- the referenced ImplementationDataType has the dynamicArraySizeProfile = VSA_LINEAR
- the referenced ImplementationDataType has two subElements where
  - one is a numerical value that represents the size indicator and
  - the other is an ImplementationDataTypeElement of category ARRAY that in turn contains a subElement that represents the platform type uint8.

⌋

[constr_5112] ImplementationDataType needs to be defined if a “new-world” variable-size ApplicationArrayDataType is mapped to a single SystemSignal

Imposition time: IT_EcuExt

⌈A SenderReceiverInterface.dataElement that is typed by a “new-world” variable-size ApplicationArrayDataType according to [TPS_SWCT_01644] (see definition in Software Component Template [4]) is only allowed to be mapped to a single SystemSignal by the SenderReceiverToSignalMapping if a DataTypeMap exists that points to both the ApplicationArrayDataType and an ImplementationDataType that fulfills the conditions of a “new-world” dynamic size array data type according to [TPS_SWCT_01645] (see definition in Software Component Template [4]).⌋

[TPS_SYST_02280] SenderReceiverInterface.dataElement is typed by a “new-world” variable-size ImplementationDataType ⌈A SenderReceiverInterface.dataElement is a candidate for a primitive SenderReceiverToSignalMapping to a single SystemSignal if all following conditions are fulfilled:

- the SenderReceiverInterface.dataElement is typed by an ImplementationDataType that fulfills the conditions of a “new-world” dynamic-size array data type according to [TPS_SWCT_01645] (see definition in Software Component Template [4]).

- the referenced ImplementationDataType has the dynamicArraySizeProfile = VSA_LINEAR
- the ImplementationDataType is of category STRUCTURE with two subElements where
  - one is a numerical value that represents the size indicator and
  - the other is an ImplementationDataTypeElement of category ARRAY that in turn contains a subElement that represents the platform type uint8.

⌋

With [TPS_SYST_02279] and [TPS_SYST_02280] it is possible to map a dataElement that represents a “new-world” variable-size array to a single SystemSignal without the usage of a data transformer.

Please note that the mapping of an “old-world” variable-size array (see definition in Software Component Template [4]) to a single SystemSignal is not supported by AUTOSAR since the Rte_Send call does not include the IN parameter [length] and the Rte_Receive API does not include the OUT parameter [length] any longer that was used in former releases to pass the number of elements in the data element.

[constr_5113] Mapping of “old-world” variable size arrays to a single SystemSignal is not supported.

Imposition time: IT_EcuExt

⌈The SenderReceiverToSignalMapping is not allowed to map a dataElement that is typed by an “old-world” variable size array defined by [TPS_SWCT_01641] and [TPS_SWCT_01642] (see definition in Software Component Template [4]) to a single SystemSignal.⌋

Note	Mapping of a sender receiver communication data element to a signal.			
Base	*ARObject*, *DataMapping*			
Aggregated by	SystemMapping.dataMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
dataElement	VariableDataPrototype	0..1	iref	Reference to the data element. **InstanceRef implemented by:** VariableDataPrototypeInSystemInstanceRef
senderToSignalTextTableMapping	TextTableMapping	0..1	aggr	This mapping allows for the text-table translation between the sending DataPrototype that is defined in the PortPrototype and the physicalProps defined for the SystemSignal.
signalToReceiverTextTableMapping	TextTableMapping	0..1	aggr	This mapping allows for the text-table translation between the physicalProps defined for the SystemSignal and a receiving DataPrototype that is defined in the PortPrototype.
systemSignal	SystemSignal	0..1	ref	Reference to the system signal used to carry the data element.

Table 5.24: SenderReceiverToSignalMapping

[constr_5466] Existence of SenderReceiverToSignalMapping.dataElement

Imposition time: IT_EcuExt

⌈For each SenderReceiverToSignalMapping, the reference to VariableDataPrototype in the role dataElement shall exist.⌋

[constr_5467] Existence of SenderReceiverToSignalMapping.systemSignal

Imposition time: IT_EcuExt

⌈For each SenderReceiverToSignalMapping, the reference to SystemSignal in the role systemSignal shall exist.⌋

[TPS_SYST_02304] Conversion of discrete parts of a CompuMethod on signal level in SenderReceiverToSignalMapping ⌈If a SystemSignal defines a CompuMethod of category TEXTTABLE, SCALE_LINEAR_AND_TEXTTABLE, and BITFIELD_TEXTTABLE, a conversion of the texttable part of the CompuMethod of the AutosarDataType of the sending DataPrototype to the SystemSignal as well as from the SystemSignal to the CompuMethod associated with the AutosarDataType of the receiving DataPrototype may be necessary.

For this purpose, meta-class SenderReceiverToSignalMapping aggregates the meta-class TextTableMapping in the roles senderToSignalTextTableMapping and signalToReceiverTextTableMapping.⌋

As explained in specification of the AUTOSAR Software Component Template [4], the TextTableMapping allows enumerated types to be connected when they have the same or similar semantics but different numerical and/or symbolic representations of those semantics.

[TPS_SYST_02305] Relevance of attribute TextTableMapping.mappingDirection in an aggregation by SenderReceiverToSignalMapping ⌈The value of attributes

- SenderReceiverToSignalMapping.senderToSignalTextTableMapping.mappingDirection
- SenderReceiverToSignalMapping.signalToReceiverTextTableMapping.mappingDirection

has no meaning and shall be ignored.⌋

Class	**TextTableMapping**			
Package	M2::AUTOSARTemplates::SWComponentTemplate::PortInterface			
Note	Defines the mapping of two DataPrototypes typed by AutosarDataTypes that refer to CompuMethods of category TEXTTABLE, SCALE_LINEAR_AND_TEXTTABLE or BITFIELD_TEXTTABLE.			
Base	*ARObject*			
Aggregated by	DataPrototypeMapping.textTableMapping, SenderRecArrayTypeMapping.senderToSignalTextTableMapping, SenderRecArrayTypeMapping.signalToReceiverTextTableMapping, SenderReceiverToSignalMapping.senderToSignalTextTableMapping, SenderReceiverToSignalMapping.signalToReceiverTextTableMapping, SenderRecRecordElementMapping.senderToSignalTextTableMapping, SenderRecRecordElementMapping.signalToReceiverTextTableMapping, SubElementMapping.textTableMapping			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
bitfieldTextTableMaskFirst	PositiveInteger	0..1	attr	This attribute can be used to support the mapping of bit field to bit field, boolean values to bit fields, and vice versa. The attribute defines the bit mask for the first element of the TextTableMapping. **Stereotypes:** atpVariation **Tags:** vh.latestBindingTime=preCompileTime
bitfieldTextTableMaskSecond	PositiveInteger	0..1	attr	This attribute can be used to support the mapping of bit field to bit field, boolean values to bit fields, and vice versa. The attribute defines the bit mask for the second element of the TextTableMapping. **Stereotypes:** atpVariation **Tags:** vh.latestBindingTime=preCompileTime
identicalMapping	Boolean	0..1	attr	If identicalMapping is set == true the values of the two referenced DataPrototypes do not need any conversion of the values.
mappingDirection	MappingDirectionEnum	0..1	attr	Specifies the conversion direction for which the TextTableMapping is applicable.
valuePair	TextTableValuePair	*	aggr	Defines a pair of values which are translated into each other.

Table 5.25: TextTableMapping

5.2.1.2 Mapping of Variable Data Prototypes with composite datatypes (Sender-Receiver Communication)

This section describes the mapping of VariableDataPrototypes typed by composite data types to SystemSignals.

It is not possible to map a VariableDataPrototype typed by composite data type directly (without any additional mechanisms) to one SystemSignal because The RTE is required to treat AUTOSAR signals transmitted using sender-receiver communication consistently. For this purpose, data transformation or SystemSignalGroups is used.

There are two ways to map a VariableDataPrototype typed by composite data type to SystemSignals/SystemSignalGroups:

1. Use data transformation and map it directly to a SystemSignal.
2. Map it to a SystemSignalGroup with SenderReceiverToSignalGroupMapping

[constr_3506] Mapping of composite data type to SystemSignals in SystemSignalGroup

Imposition time: IT_EcuExt

⌈Either all or a subset of elements of a composite data type shall be mapped to SystemSignals which shall be members of one SystemSignalGroup if no data transformation (except COM Based Transformer) is used.

There are two exceptions to this rule:

- it is allowed to map an array VariableDataPrototype consisting of UINT8 elements to exactly one SystemSignal in the context of one SenderReceiverToSignalMapping (see [TPS_SYST_01037]).
- in case the COM Based Transformer [17] is used it is the integral part of the approach to have a fixed mapping of the individual elements of composite data types to SystemSignals in a SystemSignalGroup ([TPS_SYST_02058]).

⌋

5.2.1.2.1 Data Transformation

If data transformation is used, the consistency of the composite data is assured by the transformation.

A VariableDataPrototype typed by composite data type can be mapped to one SystemSignal without any SystemSignalGroup if data transformation is used.

In that case any required mapping between the ApplicationCompositeElementDataPrototypes of the VariableDataPrototype of the connected PortPrototypes needs to be expressed by means of a PortInterfaceMapping attached to the SwConnector connecting the two PortPrototypes and not by means of two separated DataMappings (one referencing the VariableDataPrototype at the PPortPrototype and the other one referencing the VariableDataPrototype at the RPortPrototype).

During creation of a System Extract of the System Configuration Description or the creation of an ECU Extract of the System Configuration Description, this PortInterfaceMapping needs to be preserved in order to support proper deserializing transformation at the receiver side (see chapter 13.4 and 14.2).

See chapter 7 for details how to enable data transformation.

In case the COM Based Transformer [17] is used the mapping from section 7.3.3 is required.

5.2.1.2.2 Mapping via SystemSignalGroups

The VariableDataPrototype that is referenced by dataElement can be typed by an ApplicationDataType or by an ImplementationDataType. This type decides which reference is used within the SenderRecRecordElementMapping and SenderRecArrayElementMapping.

Composite DataPrototypes may nest within composite VariableDataPrototypes. Each element typed by a primitive data type of such nested composite VariableDataPrototype can be mapped to one SystemSignal of a SystemSignalGroup.

Please note that not every single element typed by a primitive data type needs to be mapped to a SystemSignal since a partial mapping is also supported that maps a subset of elements of the composite data type to separate SystemSignals of a SystemSignalGroup.

The mapping between the SystemSignal and the VariableDataPrototype is provided in the SenderReceiverToSignalGroupMapping (see Figure 5.21).

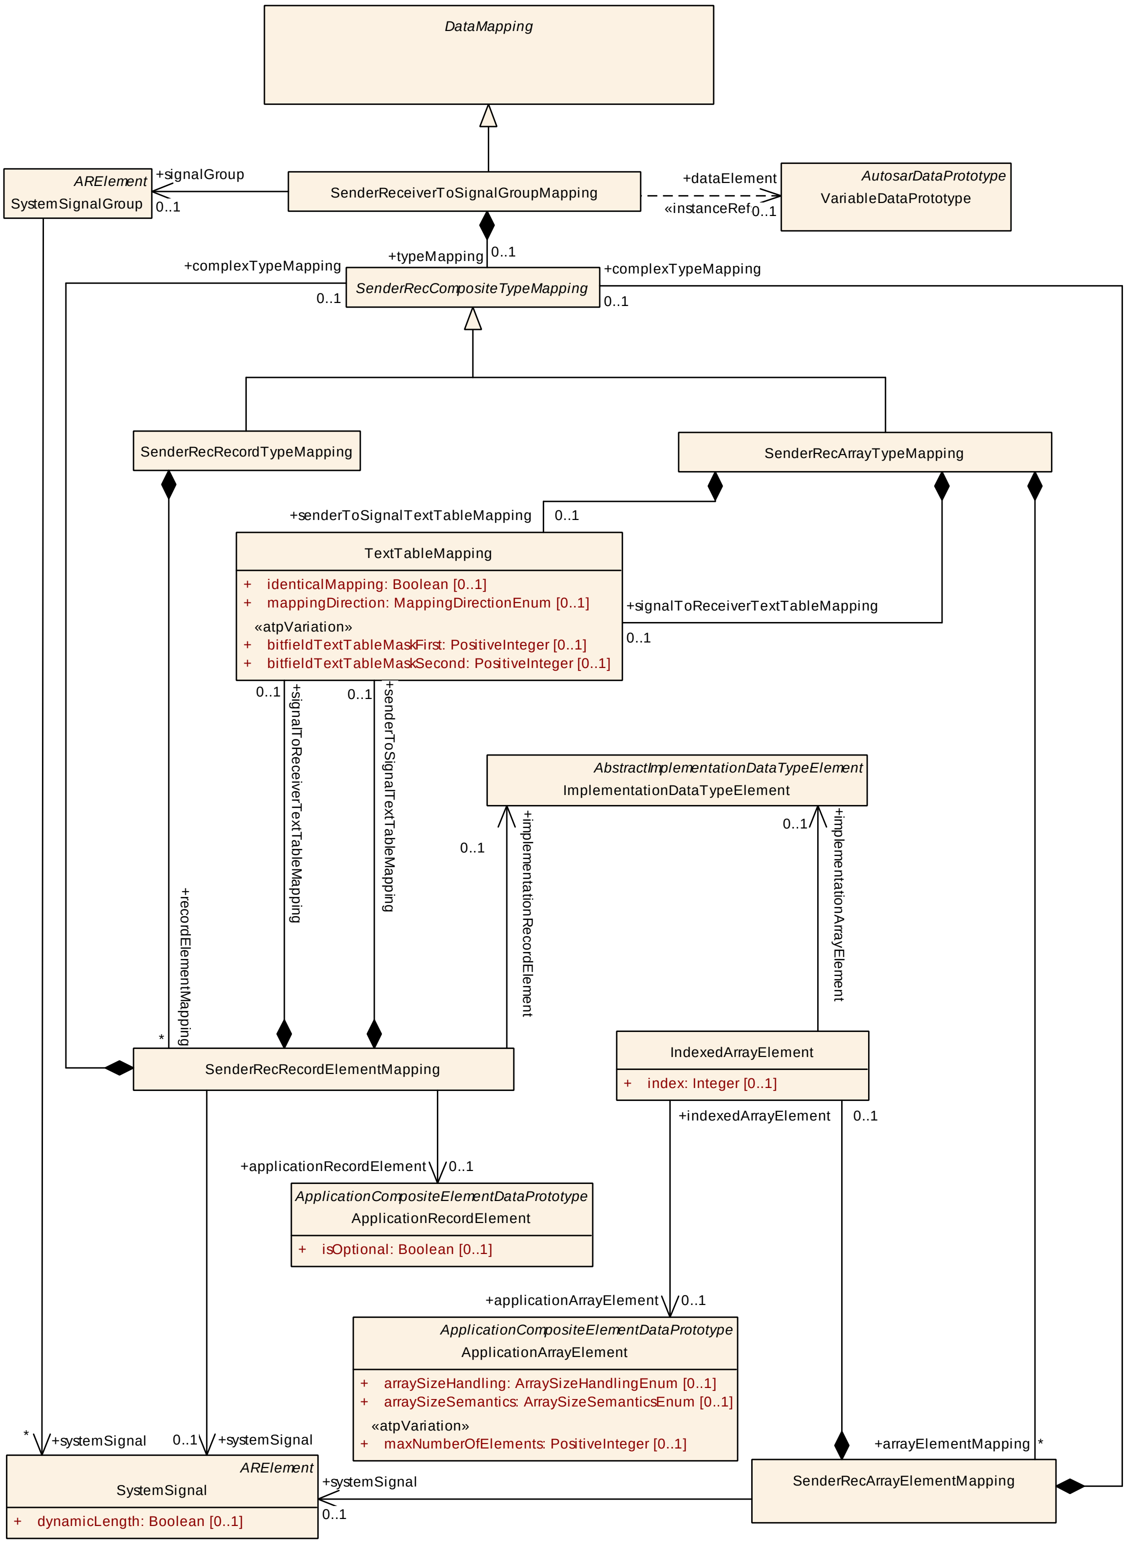

Figure 5.21: Mapping of data elements with composite data types (SenderRecCompositeTypeMapping)

[constr_3000] valid SenderRecCompositeTypeMappings

Imposition time: IT_EcuExt

⌈All SenderRecRecordElementMappings or SenderRecArrayElementMappings aggregated in the context of a given SenderReceiverToSignalGroupMapping shall reference a SystemSignal that is also referenced in the role systemSignal by the SystemSignalGroup that is referenced by the enclosing SenderReceiverToSignalGroupMapping in the role signalGroup.⌋

In other words: within the context of an SenderReceiverToSignalGroupMapping, it shall only be possible to refer to a SystemSignal that is a member of the SystemSignalGroup referenced by the SenderReceiverToSignalGroupMapping.

Please note that [constr_3000] does not demand that all leaf elements of the composite data type are actually mapped to a SystemSignal.

[TPS_SYST_02278] Existence of SystemSignals in a SystemSignalGroup that are not referenced by a SenderRecCompositeTypeMapping ⌈There are use cases where not all SystemSignals of a SystemSignalGroup are referenced by a SenderRecRecordElementMapping or a SenderRecArrayElementMapping. One example is the ComBased Transformer use case where the SystemSignalGroup contains SystemSignals that are added by additional Transformers like the E2E Transformer (e.g. CRC and Alive Counter), but only the application data element signals are mapped by the SenderReceiverToSignalGroupMapping. One additional use case is the partial mapping of composite data types where only a subset of elements of the composite data type are mapped to SystemSignals of the SystemSignalGroup.⌋

Class	**SenderReceiverToSignalGroupMapping**

Class	***SenderRecCompositeTypeMapping*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::DataMapping			
Note	Two mappings exist for the composite data types: "ArrayTypeMapping" and "RecordTypeMapping". In both, a primitive datatype will be mapped to a system signal. But it is also possible to combine the arrays and the records, so that an "array" could be an element of a "record" and in the same manner a "record" could be an element of an "array". Nesting these data types is also possible. If an element of a composite data type is again a composite one, the "CompositeTypeMapping" element will be used one more time (aggregation between the ArrayElementMapping and CompositeType Mapping or aggregation between the RecordElementMapping and CompositeTypeMapping).

Imposition time: IT_EcuExt

⌈IndexedArrayElement.implementationArrayElement shall only be used if the referenced context element (VariableDataPrototype that is referenced by the SenderReceiverToSignalGroupMapping.dataElement) is typed by an ImplementationDataType.⌋

Figure 5.22 shows a mapping example for nested composite data types.

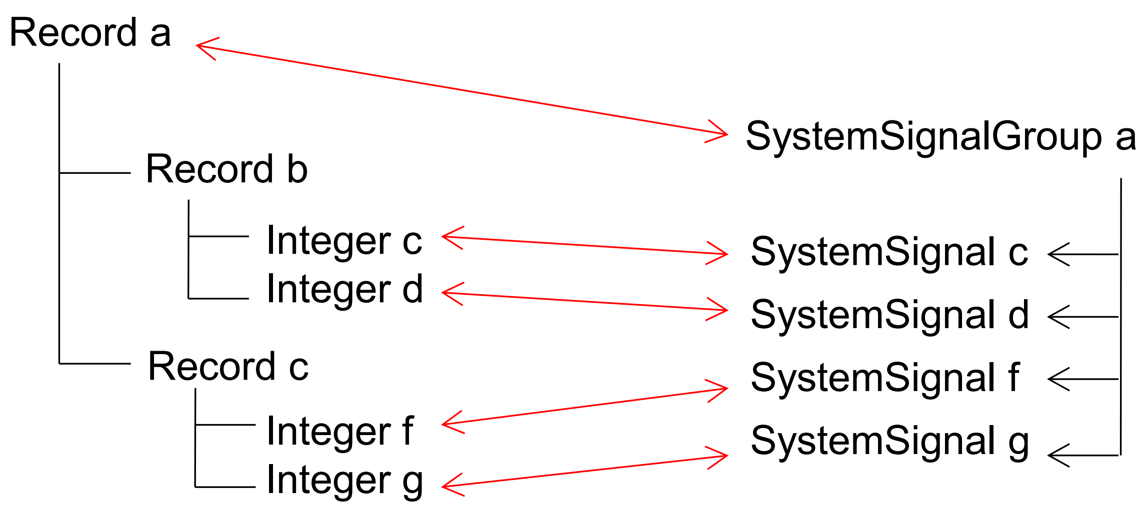

Figure 5.22: Mapping example for nested composite data types

Record a is mapped with SenderReceiverToSignalGroupMapping to a SystemSignalGroup. The content of Record a is mapped with the SenderRecRecordTypeMapping. Since the first element of *Record a* is *Record b* the SenderRecRecordElementMapping does not contain a reference to a SystemSignal because signals apply only to atomic data items. Instead it contains a complexTypeMapping with two SenderRecRecordElementMappings for *Integer c* and *Integer d*. These two elements are mapped to SystemSignals.

Please note that a partial mapping of a data element typed by composite data type in a PPortPrototype is also supported. If a VariableDataPrototype with a composite data type in a PPortPrototype is mapped to a SystemSignalGroup then it is allowed to map only a subset of elements of the composite data type that are primitives to separate SystemSignals of the SystemSignalGroup. This means that it is possible to transmit a subset of a composite data element in a ISignalGroup over the network. Figure 5.23 shows a partial mapping example for nested composite data types.

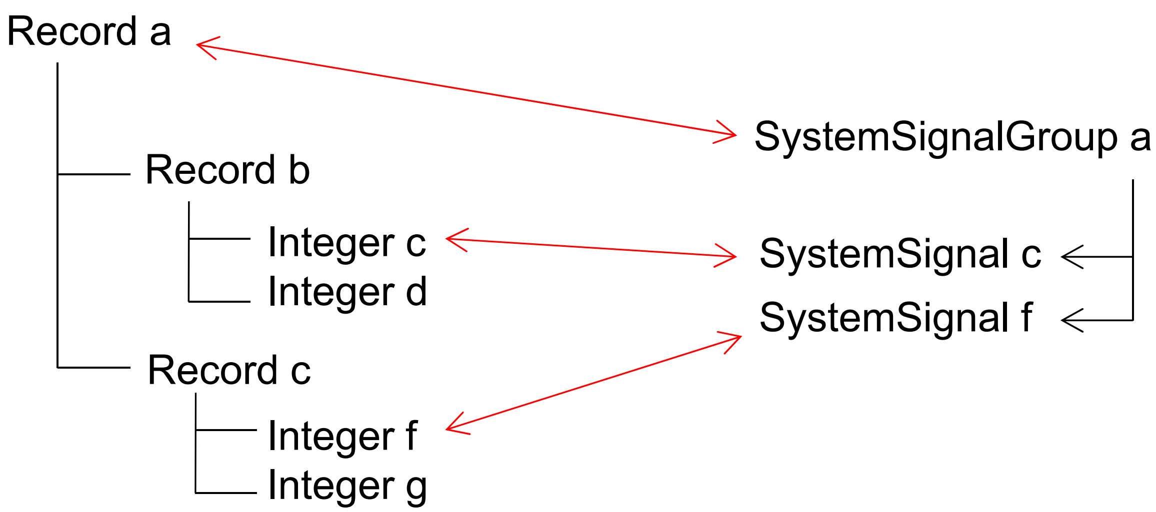

Figure 5.23: Partial mapping example for nested composite data types

[TPS_SYST_02306] Conversion of discrete parts of a CompuMethod on signal level in `SenderRecRecordElementMapping` and `SenderRecArrayTypeMapping` ⌈If a `SystemSignal` defines a `CompuMethod` of category `TEXTTABLE`, `SCALE_LINEAR_AND_TEXTTABLE`, and `BITFIELD_TEXTTABLE`, a conversion of the texttable part of the `CompuMethod` of the `AutosarDataType` of the sending `DataPrototype` to the `SystemSignal` as well as from the `SystemSignal` to the `CompuMethod` associated with the `AutosarDataType` of the receiving `DataPrototype` may be necessary.

For this purpose,

- meta-class `SenderRecRecordElementMapping` aggregates the meta-class `TextTableMapping` in the roles `SenderRecRecordElementMapping.senderToSignalTextTableMapping` and `SenderRecRecordElementMapping.signalToReceiverTextTableMapping`.
- meta-class `SenderRecArrayTypeMapping` aggregates the meta-class `TextTableMapping` in the roles `SenderRecArrayTypeMapping.senderToSignalTextTableMapping` and `SenderRecArrayTypeMapping.signalToReceiverTextTableMapping`.

⌋

As explained in specification of the AUTOSAR Software Component Template [4], the `TextTableMapping` allows enumerated types to be connected when they have the same or similar semantics but different numerical and/or symbolic representations of those semantics.

[TPS_SYST_02307] Relevance of attribute TextTableMapping.mappingDirection in an aggregation by SenderRecRecordElementMapping or SenderRecArrayTypeMapping ⌈The value of attributes

- SenderRecRecordElementMapping.senderToSignalTextTableMapping.mappingDirection
- SenderRecRecordElementMapping.signalToReceiverTextTableMapping.mappingDirection
- SenderRecArrayTypeMapping.senderToSignalTextTableMapping.mappingDirection
- SenderRecArrayTypeMapping.signalToReceiverTextTableMapping.mappingDirection

has no meaning and shall be ignored.⌋

[constr_5162] Valid TextTableMapping in the context of SenderRecRecordElementMapping

Imposition time: IT_EcuExt

⌈The aggregation of a TextTableMapping at SenderRecRecordElementMapping is only valid if the SenderRecRecordElementMapping also references a SystemSignal in the role systemSignal.⌋

Rationale: SenderRecRecordElementMapping could also be used on record elements that itself need to be broken down further. In other words if the SenderRecRecordElementMapping aggregates a complexTypeMapping it shall not aggregate a TextTableMapping.

[TPS_SYST_02308] TextTableMapping defined in the context of SenderRecArrayTypeMapping ⌈The aggregation of a TextTableMapping at SenderRecArrayTypeMapping allows for the text-table translation between all array elements of an array data type that is used in a PortPrototype of the application software and the physicalProps defined for the mapped SystemSignals.⌋

Please note that the TextTableMapping is aggregated by the SenderRecArrayTypeMapping because the same mapping rule is valid for all array elements.

The following example shows a case where an ApplicationRecordDataType is defined that contains two ApplicationRecordElements. Each ApplicationRecordElement defines a TEXTTABLE CompuMethod. One of the SystemSignals to which one of the ApplicationRecordElements is mapped has a different CompuMethod defined and therefore a TextTableMapping is created that defines the conversion of the texttable part of the CompuMethod of the AutosarDataType of the sending DataPrototype and the CompuMethod of the SystemSignal.

Listing 5.1: Example for the definition of a TextTableMapping aggregated by the SenderRecRecordElementMapping

5.2.1.3 Mapping of Client Server Operations to System Signals

This section describes the mapping of ClientServerOperations to SystemSignals (see Figure 5.24).

[TPS_SYST_01148] Mapping of IN and INOUT ArgumentDataPrototypes to callSignals ⌈The ArgumentDataPrototypes that are passed to the operation (i.e. the direction is "in") and the ArgumentDataPrototypes that are passed to and returned from the operation (i.e. the direction is "inout") are expected to be mapped to the callSignal by the serializer.⌋

[TPS_SYST_01149] Mapping of OUT and INOUT ArgumentDataPrototypes to returnSignals ⌈The ArgumentDataPrototypes that are returned from the operation (i.e. the direction is “out”) and the ArgumentDataPrototypes that are passed to and returned from the operation (i.e. the direction is “inout”) are expected to be mapped to the returnSignal by the serializer.⌋

Please note that due to DataMapping restrictions the client-server communication is only supported in AUTOSAR if the SOME/IP Transformer is used as serializer. In SOME/IP the ApplicationErrors are part of the SOME/IP Header as Return Code as described by [PRS_SOMEIP_00030] in [18]. This is the reason why the ApplicationErrors are not considered in the ClientServerToSignalMapping.

[TPS_SYST_01150] Mapping of returnSignal and callSignal to COM Signal ⌈In the ECU Configuration of the AUTOSAR COM module the returnSignal and the callSignal are expected to be mapped to COM Signals with the ComSignalType UINT8_N or UINT8_DYN.⌋

The ClientServerToSignalMapping can only map transformed data to SystemSignals because it contains no information how data shall be serialized, it only references the primitive SystemSignal which shall contain the serialized data. How to define the necessary information which serialization algorithm shall be applied can be found in chapter 7. The implementation of this algorithm is provided via a BSW module.

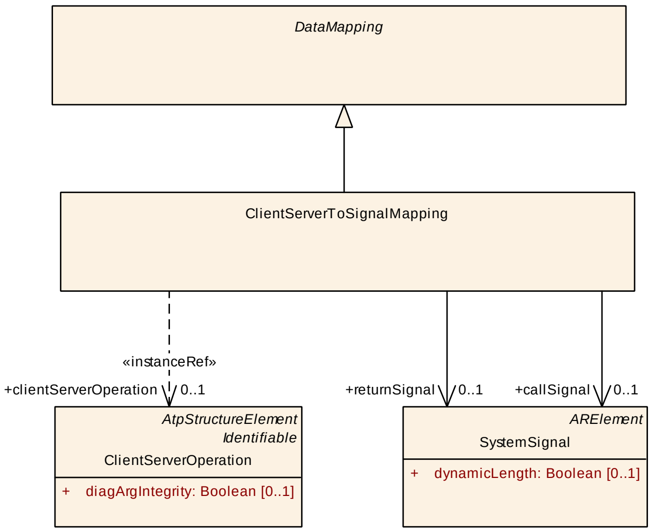

Figure 5.24: Mapping of a ClientServerOperation to a callSignal and a returnSignal

[constr_5474] Existence of ClientServerToSignalMapping.clientServer-Operation

Imposition time: IT_EcuExt

⌈For each ClientServerToSignalMapping, the reference to ClientServerOp-eration in the role clientServerOperation shall exist.⌋

[constr_3111] returnSignal in ClientServerToSignalMapping is mandatory

Imposition time: IT_EcuExt

⌈A ClientServerToSignalMapping shall always have a returnSignal defined.⌋

[constr_3215] TransformationTechnology.version and Transformation-Technology.protocol settings for request and response of a client/server communication

Imposition time: IT_SysDesc

⌈TransformationTechnology.version and TransformationTechnology.protocol shall be identical for ISignals that are derived from the same ClientServerOperation. This means that all ISignals that refer to ClientServerToSignalMapping.callSignal or to ClientServerToSignalMapping.returnSignal of the same ClientServerToSignalMapping shall have the same TransformationTechnology.protocol and Transformation-Technology.version defined.⌋

The ClientServerToSignalMapping (as any other DataMapping) defines the mapping on the level of SystemSignals (see also section 5.2). For the communication on actual PhysicalChannels (could be actual VLAN or dedicated EthernetCluster) an ISignal and a corresponding ISignalTriggering needs to be defined (see section 6.1).

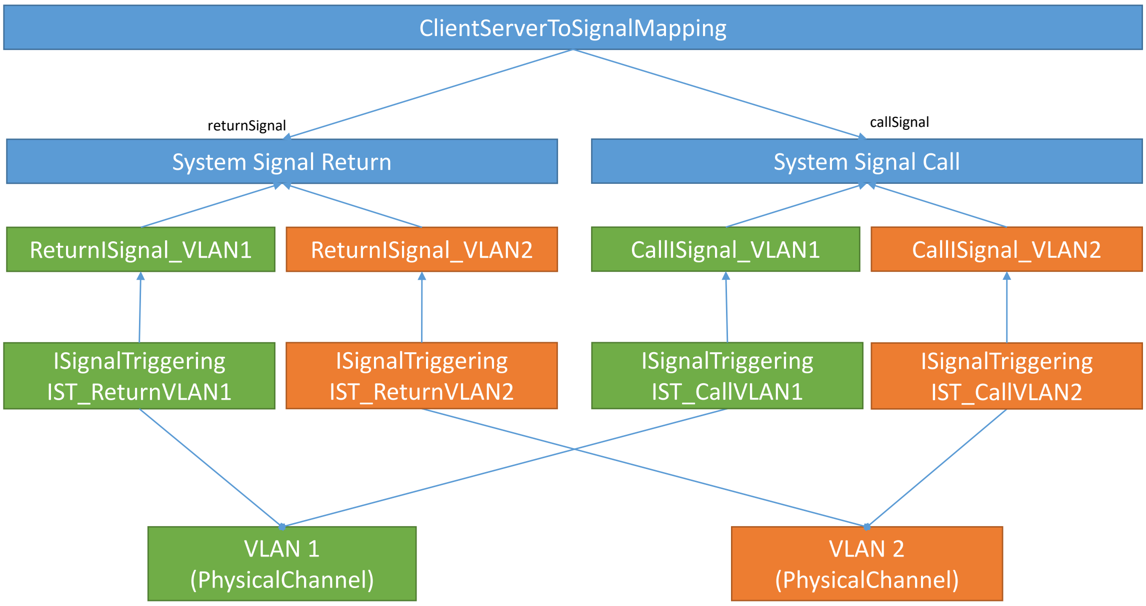

Figure 5.25: Scenario in which a SOME/IP Service with a ClientServerOperation is offered on several VLANs

In the example in figure 5.25 a server offers his service on two VLANs (could be actual VLAN or dedicated EthernetCluster). When a call arrives at the server from VLAN1 it will be propagated in the "CallISignal_VLAN1" to the RTE. The RTE takes the call message and de-serializes the payload and calls the Server. The result of the server is serialized and needs to be put into a return ISignal. But from just looking at the available ISignals for the return it is not possible to determine whether the result message has to be put into the result ISignal "ReturnISignal_VLAN1" or "ReturnISignal_VLAN2".

Thus the RTE needs to determine to which PhysicalChannel the call ISignal belongs and choose the return ISignal which is defined on the same PhysicalChannel. The ISignalTriggering defines on which PhysicalChannel an ISignal is transported, thus by determining which ISignalTriggering refers to the ISignal (in the call example ISignal: "CallISignal_VLAN1", ISignalTriggering: "IST_CallVLAN1") it is clear that the PhysicalChannel "VLAN 1" is the source of the call and thus the return message needs to go to an ISignal which is transported on that PhysicalChannel.

If a Server offers a service on several PhysicalChannels then there are some constraints to be respected in order for the RTE, Com, and LdCom to work together properly:

- Define an own ISignal-Pair (call and return) for each PhysicalChannel the service shall be offered on. These ISignals refer to the respective call and return SystemSignals.
- Only one ISignalTriggering per ISignal: each ISignal shall only be referenced by up to one ISignalTriggering.
- Whether an ISignalTriggering is relevant for a specific RTE, Com, or LdCom is determined by the ISignalTriggering referring to an ISignalPort, and that ISignalPort is member of a CommunicationConnector which belongs to the respective EcuInstance.

[constr_5273] One ISignalTriggering pair allowed per EthernetPhysicalChannel for a ClientServerOperation

Imposition time: IT_SysDesc

⌈For each EthernetPhysicalChannel at most one pair of

- ISignalTriggering that refers to an ISignal that in turn refers to a SystemSignal that is referenced by a specific ClientServerToSignalMapping in the role callSignal
- ISignalTriggering that refers to an ISignal that in turn refers to a SystemSignal that is referenced by the same ClientServerToSignalMapping in the role returnSignal

shall exist.⌋

Also it is required that a Client/Server interaction is fully provided on each PhysicalChannel, i.e. both callSignal and returnSignal shall be put onto the PhysicalChannel.

[constr_5274] ISignalTriggerings that represent the callSignal and returnSignal of the same ClientServerOperation on a PhysicalChannel shall be referenced by the same ClientServerToSignalMapping

Imposition time: IT_SysDesc

⌈If on an EthernetPhysicalChannel an ISignalTriggering that refers to an ISignal that in turn refers to a SystemSignal that is referenced by a specific ClientServerToSignalMapping in the role callSignal is defined, then another ISignalTriggering shall be aggregated by the same EthernetPhysicalChannel and that ISignalTriggering shall refer to an ISignal that in turn refers to a SystemSignal that is referenced by the same ClientServerToSignalMapping in the role returnSignal, and vice versa.⌋

5.2.1.4 Mapping of a ApplicationCompositeElementDataPrototype within a composite application data type on a System Signal (Sender-Receiver Communication)

SenderReceiverCompositeElementToSignalMapping is used to map a ApplicationCompositeElementDataPrototype that is aggregated within a composite data type (record element or an array element) to a SystemSignal.

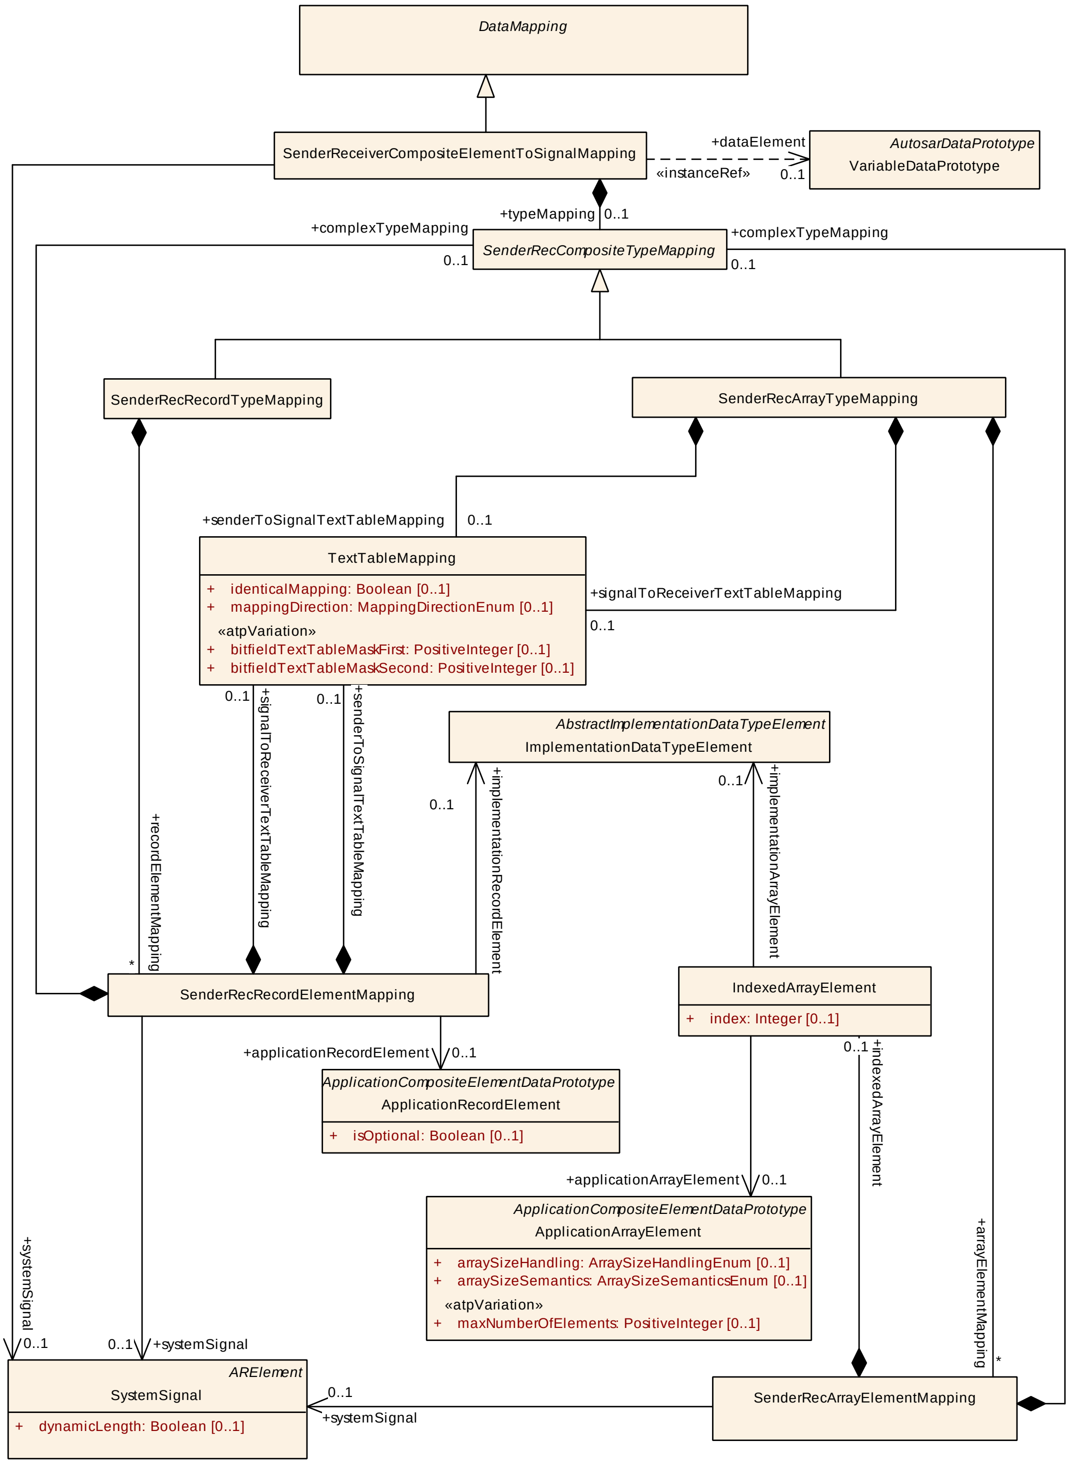

Figure 5.26: Mapping of a Variable Data Prototype which is aggregated within a composite data type on a System Signal

[constr_3058] References from SenderRecArrayElementMapping and from SenderRecRecordElementMapping to SystemSignals are not allowed within a SenderReceiverCompositeElementToSignalMapping

Imposition time: IT_EcuExt

⌈The reference from SenderRecArrayElementMapping to SystemSignal and from SenderRecRecordElementMapping to SystemSignal shall not exist if the enclosing SenderRecCompositeTypeMapping is owned by a SenderReceiver-CompositeElementToSignalMapping.⌋

[TPS_SYST_01143] DataMapping on the sender side for elements of a composite data type ⌈On the sender side, it is possible that only a subset of elements of an ApplicationCompositeElementDataPrototype of a dataElement in a PPortPrototype in its sender role is referenced by a DataMapping.⌋

Class	**SenderReceiverCompositeElementToSignalMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::DataMapping			
Note	Mapping of an Variable Data Prototype which is aggregated within a composite datatype to a System Signal (only one element of the composite data type is mapped).			
Base	*ARObject*, *DataMapping*			
Aggregated by	SystemMapping.dataMapping

dataElement	VariableDataPrototype	0..1	iref	Reference to a data element with a composite datatype from which one element is mapped to a SystemSignal. **InstanceRef implemented by:** VariableDataPrototypeInSystemInstanceRef
systemSignal	SystemSignal	0..1	ref	Reference to the SystemSignal to which one primitive of the composite type is mapped.
typeMapping	SenderRecCompositeTypeMapping	0..1	aggr	The CompositeTypeMapping maps one VariableDataPrototype of the composite data type to a SystemSignal.

Table 5.34: SenderReceiverCompositeElementToSignalMapping

SenderRecCompositeTypeMapping and all subclasses are described in section 5.2.1.2

[constr_5475] Existence of SenderReceiverCompositeElementToSignalMapping.systemSignal

Imposition time: IT_EcuExt

⌈For each SenderReceiverCompositeElementToSignalMapping, the reference to SystemSignal in the role systemSignal shall exist.⌋

[constr_5476] Existence of SenderReceiverCompositeElementToSignalMapping.typeMapping

Imposition time: IT_EcuExt

⌈For each SenderReceiverCompositeElementToSignalMapping, the aggregation of SenderRecCompositeTypeMapping in the role typeMapping shall exist.⌋

5.2.1.5 Mapping of Trigger to SystemSignal

[TPS_SYST_05001] Send a Trigger across a network ⌈In order to be able to send a Trigger across a network to trigger a RunnableEntity deployed to a different EcuInstance it is possible to define a TriggerToSignalMapping that maps a Trigger to a SystemSignal in the role systemSignal.⌋

[constr_1198] TriggerToSignalMapping.systemSignals eligible for a TriggerToSignalMapping in case no DataTransformation is used

Imposition time: IT_EcuExt

⌈The ISignal that is referenced by a SystemSignal that in turn is referenced by a TriggerToSignalMapping in the role systemSignal shall have the length attribute set to 0 if the ISignal does not reference a DataTransformation in the role dataTransformation.⌋

[constr_1199] ISignals relating to systemSignals eligible for a TriggerToSignalMapping shall use update bit in case no DataTransformation is used

Imposition time: IT_SysDesc

⌈An ISignal

- that is used to reference a systemSignal that in turn is referenced by a TriggerToSignalMapping and
- does not reference a DataTransformation in the role dataTransformation

shall be referenced by an ISignalToIPduMapping where the attribute updateIndicationBitPosition is defined.⌋

Please note that according to [TPS_SYST_02021] the updateIndicationBitPosition shall not be defined if LdCOM is used.

[constr_5258] TriggerToSignalMapping.systemSignals eligible for a TriggerToSignalMapping in case DataTransformation is used

Imposition time: IT_SysDesc

⌈The ISignal that is referenced by a SystemSignal that in turn is referenced by a TriggerToSignalMapping in the role systemSignal shall have its length attribute set to the value of BufferProperties.headerLength attribute of the respective TransformationTechnology if the ISignal references a DataTransformation in the role dataTransformation that in turn references the TransformationTechnology.⌋

For example, in case of the SOME/IP Transformer the 64 bit length covers the SOME/IP header defined by the SOME/IP Transformer (i.e. Request ID, Protocol Version, InterfaceVersion, Message Type, and Return Code) (as defined by [constr_5258] and [constr_3128]). The actual payload of the ISignal representing a trigger is 0.

[constr_5262] SystemSignal used for Trigger communication shall not be part of any SystemSignalGroup

Imposition time: IT_EcuExt

⌈A SystemSignal that is target of a TriggerToSignalMapping in the role systemSignal shall not be referenced by a SystemSignalGroup in the role systemSignal.⌋

[TPS_SYST_02365] No support of Com Based Transformer for Trigger communication ⌈Due to [constr_5262] it is not possible to define a SystemSignal which is representing a Trigger to be part of a SystemSignalGroup, thus it is not possible to define a Trigger to be processed by a Com Based Transformer (as Com Based Transformer is enabled with the ISignalGroup.comBasedSignalGroupTransformation).⌋

[TPS_SYST_05002] The value of startPosition is irrelevant ⌈The value of startPosition shall not be considered inside an ISignalToIPduMapping that references an ISignal used to reference a TriggerToSignalMapping.systemSignal that in turn is referenced by a TriggerToSignalMapping.⌋

Please note that in case of a TriggerToSignalMapping for transmission of a Trigger over the network that has the swImplPolicy set to queued the sender will not get any indication that the receiver queue is full.

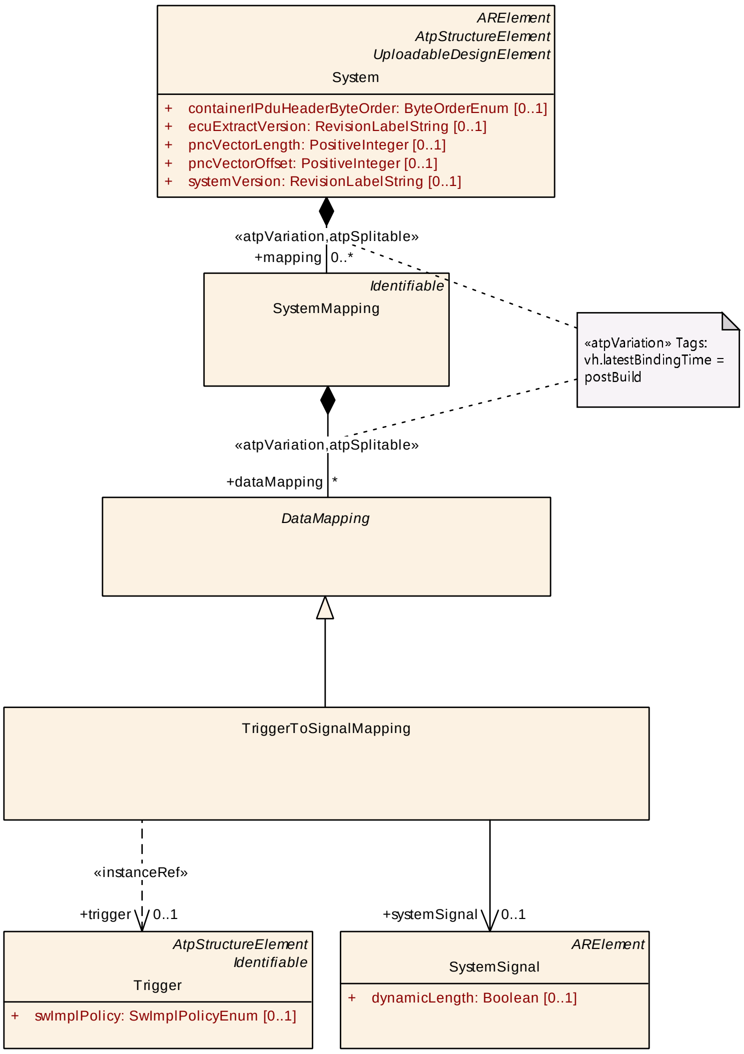

Figure 5.27: Structure of a TriggerToSignalMapping

Class	**TriggerToSignalMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::DataMapping			
Note	This meta-class represents the ability to map a trigger to a SystemSignal of size 0. The Trigger does not transport any other information than its existence, therefore the limitation in terms of signal length.

[constr_5478] Existence of TriggerToSignalMapping.trigger

Imposition time: IT_EcuExt

⌈For each TriggerToSignalMapping, the reference to Trigger in the role trigger shall exist.⌋

5.2.2 Signal Path Constraint

One task of the System Generator is to define the needed communication infrastructure (e.g. ISignals, Pdus, Frames) between ECUs. The System Generator often has the choice between alternative paths through the topology. In the example shown in Figure 5.28 the System Generator would have the choice between two paths (Path1: CAN3 or Path2: CAN1-GW-CAN2) for a signal that is send by ECU2 and is received by ECU4. If no further information is given the decision will be made e.g. by means of boundary conditions like busload, transmissions speed, etc.

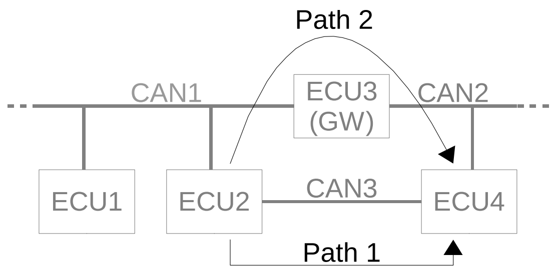

Figure 5.28: Example for a Communication Path

Signal Mapping Constraints allow to further restrict or specify the path(s) a signal is allowed to be transmitted over. A path is specified by an list of PhysicalChannels.

There exist four different constraints for signals regarding the signal path (see Figure 5.29):

[TPS_SYST_01041] CommonSignalPath definition

Upstream requirements: RS_SYST_00017

⌈The CommonSignalPath describes that two or more signals shall take the same path in the topology.⌋

[TPS_SYST_01042] ForbiddenSignalPath definition

Upstream requirements: RS_SYST_00020

⌈The ForbiddenSignalPath describes the path that one or more signals shall not take in the topology, e.g. in case of safety critical transmission.⌋

[TPS_SYST_01043] PermissibleSignalPath definition

Upstream requirements: RS_SYST_00019, RS_SYST_00016

⌈The PermissibleSignalPath describes the path one or more signals may take in the topology. If more than one PermissibleSignalPath is defined for the same signal/operation attributes, any of them may be chosen.⌋

[TPS_SYST_01044] SeparateSignalPath definition

Upstream requirements: RS_SYST_00018

⌈The SeparateSignalPath describes that two or more signals shall take separate paths in the topology e.g. in case of redundant transmission.⌋

It is also possible that the same signal is aggregated two times by the SeparateSignalPath element to indicate that this signal should be transmitted redundantly over two different paths.

The meta-model part, which describes the Communication Path constraints, will be explained in the following sections.

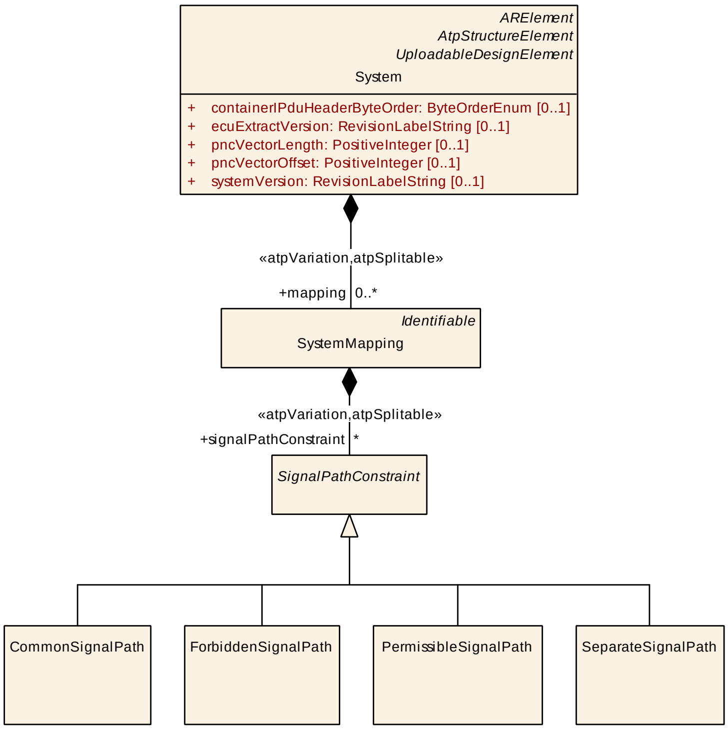

Figure 5.29: Communication Path Description (SignalPathConstraints)

5.2.2.1 CommonSignalPath

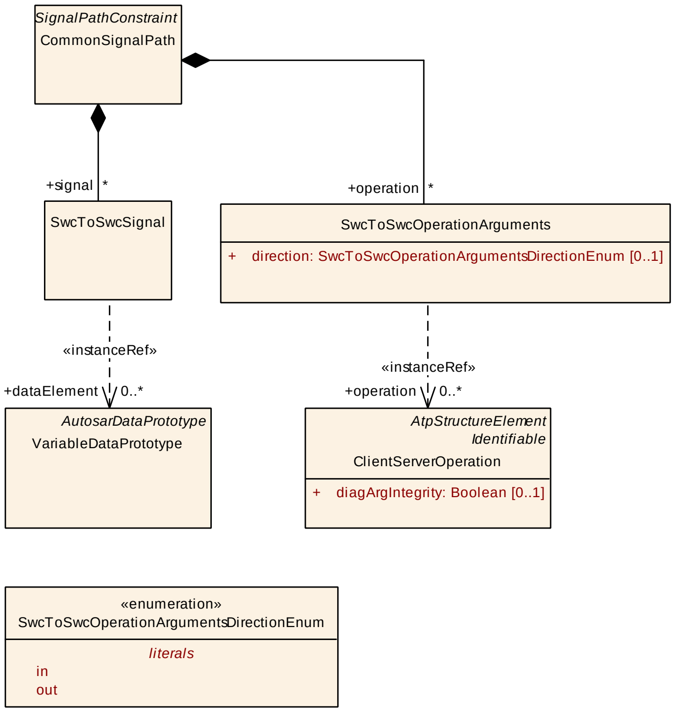

Figure 5.30: Description of signals that shall take the same way in the topology (CommonSignalPath)

Class	CommonSignalPath			
Package	M2::AUTOSARTemplates::SystemTemplate::SignalPaths			
Note	The CommonSignalPath describes that two or more SwcToSwcSignals and/or SwcToSwcOperation Arguments shall take the same way (Signal Path) in the topology.

Table 5.42: SeparateSignalPath

5.3 RTE and basic software resource estimations

Important constraints for system partitioning are the available resources on the ECUs in the system. For SW components, the resource estimations can be stated in SW component descriptions. It is however not only SW components that require resources. AUTOSAR RTE and basic software running on the ECU have resource needs as well.

The realization of the RTE and the kind of basic software to be run on a certain ECU depend on the implicit and explicit usage of all basic software by the software components. The software components need to communicate internally and with software components on other ECUs. Furthermore, they have different needs with respect to scheduling. This results in implicit use of e.g. communication and operating system software. In addition, the software components make explicit use of basic software when they e.g. utilize system services (e.g. diagnostics) and access sensors/actuators via the I/O abstraction layer or the Complex Driver abstraction layer. Thus, the resource consumption of the RTE and the basic software depend on the SW Components mapped to the ECU, since this determines the exact configuration of the RTE and the basic software.

[TPS_SYST_01126] Resource Consumption for RTE and basic software

Upstream requirements: RS_SYST_00002

⌈The resource consumption for RTE and basic software may be specified using class EcuResourceEstimation. Each estimation is performed for a specific ECU and for a specific set of SW mapped to that ECU (reference from EcuResourceEstimation to EcuInstance and SwcToEcuMapping).⌋

Different resource estimations for a specific ECU, but with different mappings may exist, e.g. for different variants of the system, or to show the difference of resource needs for different mappings. The EcuResourceEstimation aggregates the meta-class ResourceConsumption from the GenericStructure package each for RTE and basic software, which specifies stack and heap usage and execution time.

ExecutionTime and StackUsage are used to provide information on the implementation specific resource usage of the ExecutableEntity defined in the InternalBehavior of SW-Component respectively in the BswInternalBehavior of BSW Module. MemorySection documents the resources needed to load the object file containing the implementation on the ECU. HeapUsage describes the dynamic memory usage of the software.

Figure 5.34 shows the meta-model for resource estimations for RTE and basic SW.

Table 5.44: ResourceConsumption

The element `ResourceConsumption` and the sub-elements `HeapUsage`, `MemorySection`, `StackUsage` and `ExecutionTime` are described in more detail in the BSW Module Description [19].

5.4 Communication Management Mapping

The Communication Management Mapping is used to define the link between the application's communication request and the actual network topology.

Some applications may have the need to control the communication infrastructure during their run-time. So they can control at which point in time certain communication shall be enabled (requested) and when the communication can be disabled (release request). How the control interaction is to be setup is specified in the Software Component Template[4].

Which parts of the communication relies on such control is expressed using `PortGroup`s. The `PortGroup` collect the set of `PortPrototype`s which shall be available when the application requests communication.

The handling of communication management comes in two flavors, defined by the category of the PortGroup:

- PARTIAL_NETWORKING
- MODE_MANAGEMENT

PortGroups of category PARTIAL_NETWORKING determine to control the communication via Partial Network Clusters (see Section 5.4.1).

PortGroups of category MODE_MANAGEMENT determine to control the communication directly via ComManager (see Section 5.4.2). This is specifically required in cases where no partial networking is used or on network which do not support partial networking (like Lin).

5.4.1 Partial Networking

The AUTOSAR BSW stack supports power saving during vehicle operation time with the partial networking mechanism. This mechanism allows to shut down and startup the bus communication interfaces of groups of ECUs (Partial Network Cluster) during normal bus communication.

On the VFB Level Partial Networks are represented by Virtual Function Clusters and are described with PortGroups. The Virtual Function Cluster groups the communication necessary to realize one or more vehicle functions that can become activated/deactivated during normal vehicle operation. Virtual Function Clusters are described in more detail in [4]. The Virtual Function Clusters are mapped onto Partial Network Clusters.

There are two variants of the partial networking mechanism:

- The *static* partial networking mechanism where the mapping of Partial Network Clusters (PNCs) to Virtual Function Clusters (and thus ECUs) is defined statically during vehicle development and does not change afterwards.
- The *dynamic* partial networking mechanism that enables changes of the mapping between PNCs and ECUs during life time of a vehicle by introducing a learning algorithm (for details, see chapter 5.4.1.4).

The use of partial networking in general is defined based on the element PncMapping. If partial networking is used, the *dynamic* partial networking is then further defined by the attribute dynamicPncToChannelMappingEnabled of the element CommunicationConnector.

[TPS_SYST_01133] Partial Network Clusters

Upstream requirements: RS_SYST_00042

⌈Partial Network Clusters are realized with ISignalIPduGroups using PncMapping.⌋

Each PncMapping has the ability to define relations to ISignalIPduGroups, PdurIPduGroups, and PhysicalChannels. These relations are used to describe the impact of a PNC on the respective networking artifacts. The realization of those relationships is typically to be implemented in the Basic Software Mode Manager (BswM).

- PncMapping.pncGroup (referring to ISignalIPduGroup) is used to define which Com ISignalIPduGroups shall be enabled when this PNC is active. The use-case is to enable/disable Com ISignalIPdus, especially periodic behavior like cyclic sending and time-out monitoring.
- PncMapping.pncPdurGroup (referring to PdurIPduGroup) is used to define which PdurIPduGroups shall be enabled when this PNC is active. The use-case is to enable/disable Pdus which typically are not passing the Com module (e.g. Pdus going through LdCom, Diagnostic IPdus, Gatewayed IPdus).
- PncMapping.physicalChannel (referring to PhysicalChannel) is used to define which PhysicalChannels shall be enabled when this PNC is active. The use-case is to enable/disable the whole PhysicalChannel and allows to also cover Pdus which neither pass the Com module nor the Pdu Router module (e.g. NM).

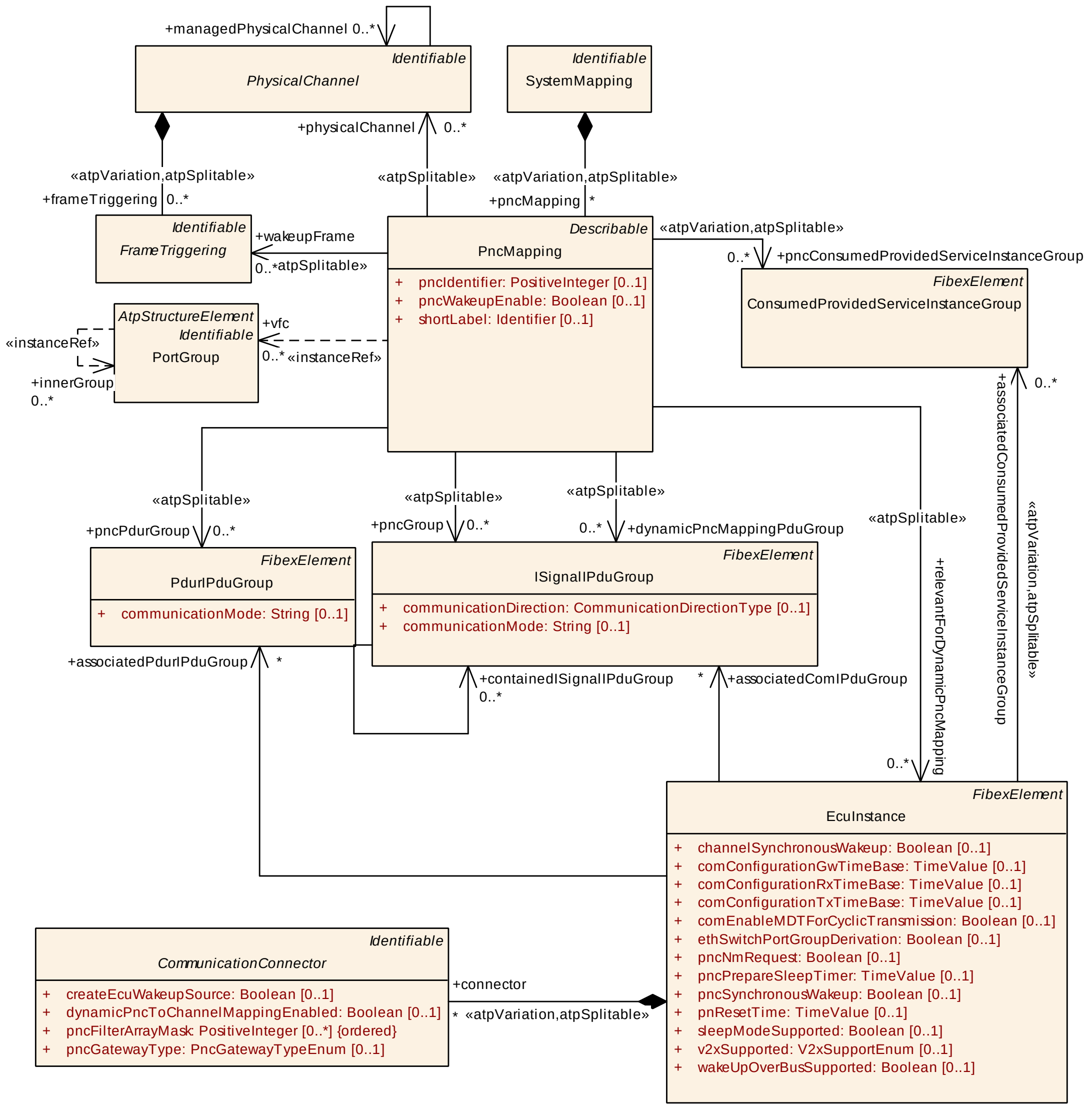

Figure 5.35: Mapping of Virtual Function Clusters onto Partial Network Clusters

Class	**PncMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::PncMapping			
Note	Describes a mapping between one or several Virtual Function Clusters onto Partial Network Clusters. A Virtual Function Cluster is realized by a PortGroup. A Partial Network Cluster is realized by one or more IPduGroups.

Attribute	*Type*	*Mult.*	*Kind*	*Note*

▽

△

Class	**PncMapping**			
dynamicPnc MappingPdu Group	ISignalIPduGroup	*	ref	Reference to an ISignalIPduGroup that allows mapping of this PNC without statically mapping this PNC directly to a channel. This is needed to describe dynamic PNCs that can be learned only at run-time and which have also a relation to an ISignalIPduGroup. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=dynamicPncMappingPduGroup atp.Status=draft
ident	PncMappingIdent	0..1	aggr	This adds the ability to become referrable to PncMapping.
physical Channel	PhysicalChannel	*	ref	This reference maps the partial network to a communication channel. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=physicalChannel
pncConsumed Provided ServiceInstance Group	ConsumedProvided ServiceInstanceGroup	*	ref	ConsumedProvidedServiceInstanceGroup used in a Partial Network Cluster. This reference is optional, since this could be used for starting and stopping Consumed ProvidedServiceInstanceGroup according the requested partial network, but is not necessarily needed. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=pncConsumedProvidedServiceInstance Group.consumedProvidedServiceInstanceGroup, pnc ConsumedProvidedServiceInstanceGroup.variation Point.shortLabel vh.latestBindingTime=postBuild
pncGroup	ISignalIPduGroup	*	ref	IPduGroup participating in a Partial Network Cluster. This reference is optional in case an ecu extract has only indirect pnc access, i.e. ecu is not directly connected to a network which supports partial network. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=pncGroup
pncIdentifier	PositiveInteger	0..1	attr	Identifer of the Partial Network Cluster. This number represents the absolute bit position of this Partial Network Cluster in the NM Pdu.
pncPdurGroup	PdurIPduGroup	*	ref	This reference maps the Partial Network Cluster to a set of PdurIpduGroups. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=pncPdurGroup
pncWakeup Enable	Boolean	0..1	attr	If this parameter is available and set to true then this PNC will be woken up as soon as a channel wakeup occurs on a channel where this PNC is assigned to. This is ensured by adding this PNC to the corresponding channel wakeup sources during upstream mapping.
relevantFor DynamicPnc Mapping	EcuInstance	*	ref	Reference to a PNC Gateway ECU for PNCs which do not have a static channel mapping. This is needed to describe dynamic PNCs that can be learned only at run-time and which have no relation to an ISignalIPdu Group. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=relevantForDynamicPncMapping atp.Status=draft
shortLabel	Identifier	0..1	attr	This attribute specifies an identifying shortName for the PncMapping. It shall be unique in the System scope.

▽

△

Class	PncMapping			
vfc	PortGroup	*	iref	Virtual Function Cluster to be mapped onto a Partial Network Cluster. This reference is optional in case that the System Description doesn't use a complete Software Component Description (VFB View). This supports the inclusion of legacy systems. **InstanceRef implemented by:** PortGroupInSystem InstanceRef
wakeupFrame	FrameTriggering	*	ref	Reference to collection of FrameTriggerings that are used for the wakeup of this PNC (Application Frames or Nm Frames can be used). This reference is only valid if this EcuExtract represents an ECU which has direct PNC access, i.e. ECU is directly connected to a network which supports partial network. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=wakeupFrame

Table 5.45: PncMapping

[constr_5479] Existence of PncMapping.pncIdentifier

Imposition time: IT_SysDesc

⌈For each PncMapping, the attribute pncIdentifier shall exist.⌋

[constr_3039] pncIdentifier range

Imposition time: IT_SysDesc

⌈The pncIdentifier value shall be in the range of 8..63 for normal CAN and in the range of 8..511 for CAN FD, FlexRay and Ethernet.⌋

Note: Older ECUs with a smaller PNC range can be used together with new ECUs with a larger PNC range (e.g. when NM PDU length and PNC Range increased in the next model year and some ECUs are overtaken). But take care that in that case the older ECUs cannot react on PNC identifiers that are beyond their smaller range as they will be ignored by those older ECUs.

[TPS_SYST_03067] Definition of pncVectorOffset ⌈The attribute System.pncVectorOffset shall define the common start byte position of the PNC vector for all NM messages in the System.⌋

[TPS_SYST_03068] Definition of pncVectorLength ⌈The attribute System.pncVectorLength shall define the maximum PNC vector length from all NM messages of the System.⌋

Partial Networks are considered System wide. If a specific PhysicalChannel has a limited payload size and thus is not able to transport the entire PNC Vector information in the payload of the NM messages it is possible to define a shortened PNC

Vector on that specific NmCluster (where that NmCluster configures the NM behavior on that CommunicationCluster or in case of Ethernet the PhysicalChannel representing a VLAN).

[constr_3687] Limited value range for NmCluster.pncClusterVectorLength

Imposition time: IT_SysDesc

⌈The value of NmCluster.pncClusterVectorLength shall be equal or smaller than System.pncVectorLength.⌋

[constr_3198] Uniqueness of PncMapping.shortLabel

Imposition time: IT_SysDesc

⌈If the optional shortLabel attribute is used it shall be unique in the System scope.⌋

The runtime information that is used to coordinate the request/release information of all partial networks is called pncVector. The size and position of the pncVector inside the NmPdu is globally defined in the System class in chapter 1.3. The size might be reduced using the optional NmCluster.pncClusterVectorLength attribute.

In the system description the NmPdus are described based on the actual network interaction (i.e. an ECU sends one NmPdu per network and receives a set of NmPdus).

NmPdus that define the existence of NM user data via the existence of the attribute iSignalToIPduMapping shall be referenced by corresponding PduTriggerings where the attribute iPduPort exists accordingly. This is also reflected by [TPS_SYST_01057].

NmPdus that define the existence of NM user data via the definition of NmPdu.nmDataInformation shall not be referenced by PduTriggerings because neither Com nor PduR are involved in the transmission (which lets the Nm module talk to the bus interface directly).

Please note that a pncVector is transmitted as byte array, where each bit of the byte array represents one particular partial network cluster. The AUTOSAR stack handles a PNC bit vector as byte array data type.

[constr_3040] Restriction of pncIdentifier values

Imposition time: IT_SysDesc

⌈The pncIdentifier value shall be within the range described by pncVectorOffset and pncVectorLength.⌋

[constr_3146] Partial Networking timing constraint

Imposition time: IT_SysDesc

⌈For Partial Networking the following timing constraints shall be ensured:

- CAN / Ethernet: (pnResetTime + pncPrepareSleepTimer) < nmNetwork-Timeout
- FlexRay: (pnResetTime + pncPrepareSleepTimer) < nmReadySleepTime

⌋

[TPS_SYST_02145] Default behavior for not defined nmPncParticipation
⌈When NmCluster.nmPncParticipation is set to *true* or is not defined this NmCluster shall contribute to the partial network mechanism.⌋

[constr_3323] Relation between NmCluster.nmPncParticipation and PncMapping.pncGroup

Imposition time: IT_SysDesc

⌈If a PncMapping references an ISignalIPduGroup in role pncGroup which in turn

- contains (either directly or via one of its subordinate ISignalIPduGroups referenced in role containedISignalIPduGroup) ISignalIPdus that are referenced by a PduTriggering in role iPdu which in turn
- is composed by a PhysicalChannel in role pduTriggering which in turn
- is composed by CommunicationCluster in role physicalChannel which in turn
- is referenced by an NmCluster in role communicationCluster,

then this NmCluster shall have its nmPncParticipation attribute set to TRUE unless the PhysicalChannel is referenced in the role managedPhysicalChannel.⌋

[constr_3484] PncMapping that refers a managedPhysicalChannel shall also refer the managing PhysicalChannel

Imposition time: IT_SysDesc

⌈If a PncMapping refers to a PhysicalChannel (either directly in the role physicalChannel or indirectly by referencing an ISignalIPduGroup in the role pncGroup) and this PhysicalChannel is referenced in the role managedPhysicalChannel, then the according managing PhysicalChannel (the source of the managedPhysicalChannel reference) shall also be referenced by the PncMapping (either directly in the role physicalChannel or indirectly by referencing an ISignalIPduGroup in the role pncGroup).⌋

Note that [constr_3484] ensures that the managing PhysicalChannel is part of the same PNC as the managedPhysicalChannels.

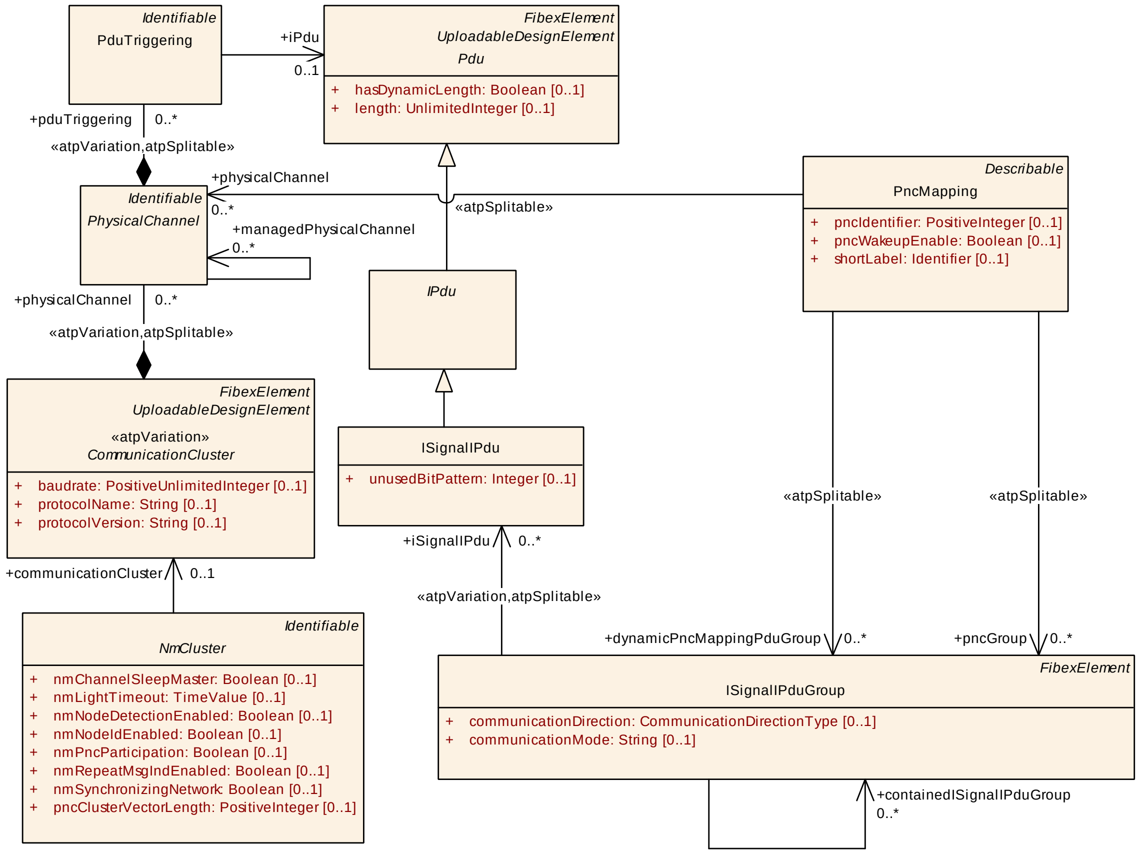

Figure 5.36: Relation between NmCluster.nmPncParticipation and PncMapping.pncGroup

[TPS_SYST_02146] Explicit definition of pncVector at NmPdu ⌈If there is an ISignalToIPduMapping aggregated by NmPdu that fully matches the interval defined by pncVectorOffset and pncVectorLength then the corresponding ISignal represents the pncVector.⌋

Attributes used to configure the Partial Network Wakeup of one specific Ecu are described in chapter 3.3.1.4.

[TPS_SYST_03073] Derivation of NmPnFilterMaskByte

Status: DRAFT
Upstream requirements: RS_SYST_00042

⌈The CommunicationConnector.pncFilterArrayMask is configured per CommunicationConnector. This data mask is calculated over the whole payload of the NmPdu ignoring the leading bytes which do not contain pncVector information. The number of leading bytes which shall be ignored is equivalent to the value of System.pncVectorOffset.⌋

Example: For pncFilterArrayMask = 2^{63} and pncVectorOffset = 2, pncIdentifier with number 63 in a NmPdu will be masked (see Figure 5.37).

NmPdu	Byte 0								Byte 1								Byte 2								Byte 3							
Absolute bit position	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
PNC identifiers				N	O	T					U	S	E	D			23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24

NmPdu	Byte 4								Byte 5								Byte 6								Byte 7							
Absolute bit position	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
PNC identifiers	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56

Figure 5.37: Example of masked pncIdentifiers in a NmPdu

Note that only pncIdentifier =< 63 can be used for the Filter mask, even if NM PDUs are configured to be larger than 8 Byte and the PncVector defined in NM user data exceeds the first 8 Byte.

5.4.1.1 Partial Networking and managed Ethernet switch

On switched Ethernet networks it is possible to let the Ethernet switch be managed by an AUTOSAR ECU. In this case the configuration and the behavior of the CouplingElement with couplingType=switch are controlled by the host ECU.

For the usage of Partial Networking on switched Ethernet networks with managed CouplingElements the following use-case applies:

Depending on the requested Partial Networks it is possible to switch off Ethernet switch ports (CouplingPorts) which are not involved in any currently active communication ([TPS_SYST_03055]). The time delay to switch off the CouplingPorts shall be in line with the used Network Management timing to avoid switching off the CouplingPorts before the Network Management has decided to go to sleep ([constr_3616]).

[TPS_SYST_03055] Semantics of EthernetCluster.couplingPortSwitchoffDelay ⌈EthernetCluster.couplingPortSwitchoffDelay, if defined, is used to configure a host ECU to delay a switch off of a CouplingPort.⌋

If using Partial Networks and the possibility to switch off Ethernet switch ports (CouplingPorts), it is possible to switch on CouplingPorts for a certain amount of time, as defined in EthernetCluster.couplingPortStartupActiveTime ([TPS_SYST_03054]). This is used to enable the host ECU (ECU that maintains an Ethernet switch) to listen to the network and wait for couplingPortStartupActiveTime to receive Partial Network information. If Partial Network information is received within couplingPortStartupActiveTime, then the according PNCs and the Ethernet switch will be requested. With this Partial Network related request the controlling of the Ethernet switch ports will be done as described in [TPS_SYST_03055]). The remaining Ethernet switch ports will be switched off after couplingPortStartupActiveTime expires ([TPS_SYST_03054])).

[TPS_SYST_03054] Semantics of EthernetCluster.couplingPortStartupActiveTime ⌈EthernetCluster.couplingPortStartupActiveTime, if defined, is used to configure a host ECU to detect a wake-up and wait to receive a Partial Network information. This also applies if a host ECU detects a reset as wake-up reason and listens to the network if Partial Network information is available on that network.⌋

In order to describe the relationships between Partial Networks and Ethernet switch ports an optional reference from CouplingPort to a PncMappingIdent in the role pncMapping is defined.

[constr_3615] Existence of EthernetCluster.couplingPortSwitchoffDelay

Imposition time: IT_SysDesc

⌈The attribute EthernetCluster.couplingPortSwitchoffDelay shall be defined if at least one EcuInstance connected to that EthernetCluster has the attribute ethSwitchPortGroupDerivation set to TRUE.⌋

[constr_3616] Value of EthernetCluster.couplingPortSwitchoffDelay

Imposition time: IT_SysDesc

⌈If defined, the value of EthernetCluster.couplingPortSwitchoffDelay shall be greater than UdpNmCluster.nmNetworkTimeout + UdpNmCluster.nmWaitBusSleepTime of the respective EthernetCluster.⌋

[constr_3617] Existence of EthernetCluster.couplingPortStartupActiveTime

Imposition time: IT_SysDesc

⌈The attribute EthernetCluster.couplingPortStartupActiveTime shall be defined if at least one EcuInstance connected to that EthernetCluster has the attribute ethSwitchPortGroupDerivation set to TRUE.⌋

[constr_3618] Value of EthernetCluster.couplingPortStartupActiveTime

Imposition time: IT_SysDesc

⌈If defined, the value of EthernetCluster.couplingPortStartupActiveTime shall be greater than UdpNmCluster.nmNetworkTimeout + UdpNmCluster.nmWaitBusSleepTime of the respective EthernetCluster.⌋

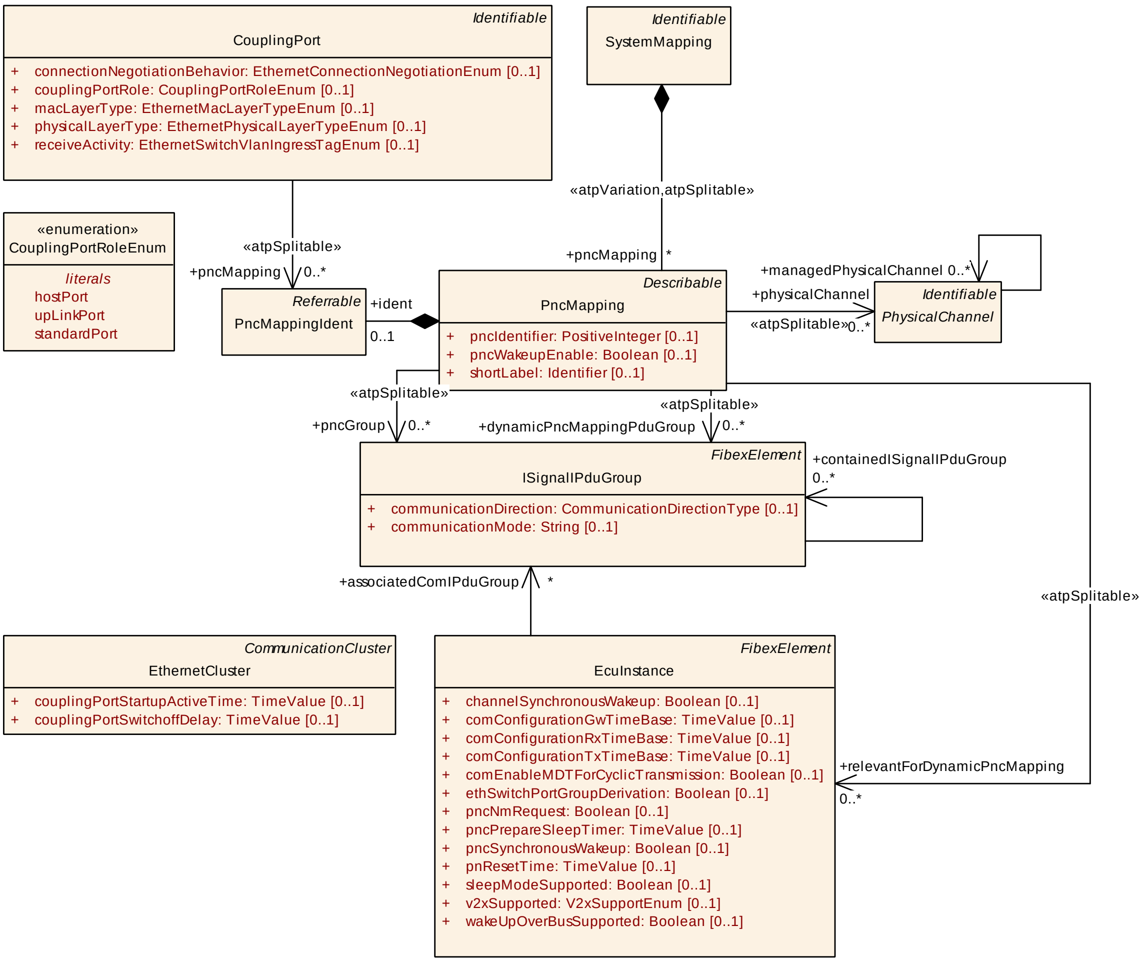

Figure 5.38: Partial Networking and managed Ethernet switch

The example in figure 5.39 illustrates the setup of an host ECU which manages 2 Ethernet switches.

The port `1` of `Switch 1` is a `hostPort`.

The port `5` of `Switch 1` and port `1` of `Switch 2` are `upLinkPort`s.

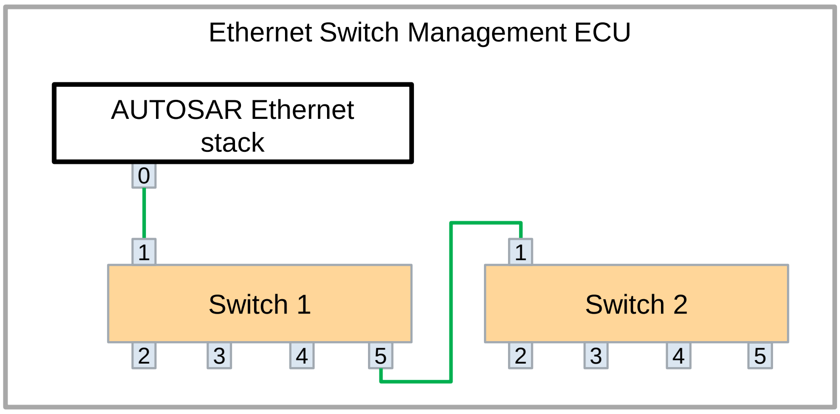

Figure 5.39: Example of managed Ethernet switches

[constr_3523] CouplingPort and PncMapping in the scope of an EthernetPhysicalChannel

Imposition time: IT_SysDesc

⌈If

- a CouplingPort referring to an EthernetPhysicalChannel – via a VlanMembership – references at least one PncMapping
- and that PncMapping contains PDUs – via the assignment of PncMapping.pncGroup – that are transported on this EthernetPhysicalChannel

then every CouplingPort referring to that EthernetPhysicalChannel shall reference at least one PncMapping as well.⌋

If a CouplingPort referring to an EthernetPhysicalChannel – via a VlanMembership – references no PncMapping, then any other CouplingPort referring to that EthernetPhysicalChannel shall either

- not reference any PncMapping or
- reference only PncMappings which have no relation (according to [TPS_SYST_03080]) to that EthernetPhysicalChannel.

The rational for [constr_3523] is that all CouplingPorts aggregated by a CouplingElement are derived to EthSwtPorts of an Ethernet switch in the ECU configuration. EthSwtPorts are controlled exclusively either via VLAN membership or via PNC membership.

If EthSwtPorts are controlled via VLAN membership, then the EthSwtPorts are activated as soon as the first relevant VLAN is activated and deactivated as soon as the last VLAN, where this EthSwtPort belongs to, is de-activated.

If EthSwtPorts are controlled via PNC membership, then the EthSwtPorts are activated as soon as the first relevant PNC is activated and deactivated as soon as the last PNC, where this EthSwtPort belongs to, is de-activated.

The PNC membership is modeled upon VLAN membership and could span across multiple VLANs. Thus, the modelling of PNC membership for CouplingPorts need to respect the VLAN membership, since the EthSwtPorts are controlled exclusively either via the PNC membership or the VLAN membership.

If a PNC is requested and the EthSwtPorts are controlled via PNC membership, then all VLANs and EthSwtPorts, which are associated with the PNC membership, are activated. As soon as VLAN membership and PNC membership have a relation, VLANs are controlled via a PNC request. The modeling needs to ensure per VLAN, that either all referencing CouplingPorts have no reference to a PNC mapping or the CouplingPorts referring different PNC mappings which have no relation to the affected VLANs. This ensures the mutual exclusive control of EthSwtPorts either via VLAN membership or PNC membership.

[TPS_SYST_03018] Aggregation of PNCs at the hostPort ⌈A CouplingPort with couplingPortRole set to hostPort shall reference all PncMappings that are referenced by any CouplingPorts of the same CouplingElement and all CouplingElements connected to this CouplingElement.⌋

[constr_3524] Definition of couplingPortRole on CouplingPort for managed CouplingElement

Imposition time: IT_SysDesc

⌈A managed CouplingElement shall have either

- at most one CouplingPort with couplingPortRole set to hostPort or
- at least one CouplingPort with couplingPortRole set to upLinkPort.

⌋

[constr_3525] Connection of CouplingPort with couplingPortRole set to upLinkPort

Imposition time: IT_SysDesc

⌈A CouplingPort with couplingPortRole set to upLinkPort shall be connected to exactly one other CouplingPort with couplingPortRole set to upLinkPort.⌋

[TPS_SYST_03020] Default value for CouplingPort.couplingPortRole if not defined ⌈If no value for the attribute CouplingPort.couplingPortRole is defined then standardPort shall be assumed.⌋

[TPS_SYST_03019] Modeling of CouplingPorts for managed CouplingElement ⌈Only CouplingPorts that participate in the communication of a managed CouplingElement shall be modeled in the System Description.⌋

All other ports of an Ethernet switch are not modeled. The expected behavior of unmodeled Ethernet switch ports on runtime:

1. the Ethernet switch driver switches off this Ethernet switch ports during its initialization
2. unmodeled Ethernet switch ports shall never be switched on.

5.4.1.2 Partial Network Gateway

As Partial Networks are spread over multiple networks their state has to be synchronized by gateway ECUs connected to a Partial Network on more than one network. Therefore a gateway mechanism is available where per network it can be configured if the network takes part in Partial network gateway algorithm or not. When more than one gateway is connected to one network then only one gateway shall be configured as main gateway.

[constr_5093] pncGatewayType and PhysicalChannel

Imposition time: IT_SysDesc

⌈When multiple CommunicationConnectors with pncGatewayType set to a value other than none are referenced by the same PhysicalChannel then only up to one CommunicationConnector shall have the pncGatewayType set to active.⌋

An ECU having a Partial Network connected to more than one network may not necessarily coordinate this Partial Network. There can be uses-cases where such an ECU is connected to multiple networks where this Partial Network is relevant but all of these networks are handled by the same gateway or by various gateways connected on another network. In this case the ECU does not coordinate the Partial Network.

[constr_5094] pncGatewayType and ECU

Imposition time: IT_SysDesc

⌈When an ECU is connected to more than one PhysicalChannel and has a relation to a Partial Network then all CommunicationConnectors of this ECU where this Partial Network is related to shall have the pncGatewayType value either set to none or to a value different than none (i.e. active or passive).⌋

Hint: This constraint ensures that an ECU either coordinates a Partial Network on all of its connected channels or on none.

5.4.1.3 Checking the consistency of partial network clusters (PNC)

The gateway ECUs participating in the synchronization of partial network requests are called PNC-Coordinators. Considering the system nature of PNC-Coordinators an example setup might look like sketched in figure 5.40.

It is essential to define to relation of particular PNCs and PhysicalChannels as well as the relation of PNCs and EcuInstances.

[TPS_SYST_03080] PhysicalChannel involved in a particular PNC

Upstream requirements: RS_SYST_00042

⌈The involvement of a PhysicalChannel in a particular PNC can be defined in several ways:

- direct reference from PncMapping to PhysicalChannel in the role physicalChannel

- PncMapping refers to a PdurIPduGroup in the role pncPdurGroup where that PdurIPduGroup refers to at least one PduTriggering owned by the PhysicalChannel
- PncMapping refers to a ISignalIPduGroup in the role pncGroup where that ISignalIPduGroup (or any ISignalIPduGroup.containedISignalIPduGroup of that ISignalIPduGroup) refers to an ISignalIPdu and that ISignalIPdu is referenced by a PduTriggering owned by the PhysicalChannel
- PncMapping refers to a ConsumedProvidedServiceInstanceGroup in the role pncConsumedProvidedServiceInstanceGroup where that ConsumedProvidedServiceInstanceGroup in turn refers to a ProvidedServiceInstance or ConsumedServiceInstance and these refer to a SoConIPduIdentifier that refers to a PduTriggering owned by the PhysicalChannel

⌋

Any of the above listed cases can overlap, thus a PhysicalChannel may be directly referenced and additionally there may exist a reference to a qualified ISignalIPduGroup.

[TPS_SYST_03081] EcuInstance involved in a particular PNC

Upstream requirements: RS_SYST_00042

⌈An EcuInstance is involved in a PNC if at least one PhysicalChannel is involved in that PNC according to [TPS_SYST_03080] and that PhysicalChannel refers to a CommunicationConnector in the role commConnector and that CommunicationConnector is aggregated at the EcuInstance in the role connector.⌋

Some observations and assumptions on the example given in figure 5.40: Each ECU connected to more than one PhysicalChannel may be configured as a PNC-Coordinator. In the sketched example the PNC-Coordinators are *PNC-Coor1*, *PNC-Coor2*, and *PNC-Coor3*. *PNC-Coor1* and *PNC-Coor3* coordinate *PNC1* and *PNC3*. *PNC-Coor2* coordinates only *PNC1*. *PNC-Coor3* coordinates *PNC1* on channels *Ch1*, *Ch2*, and *Ch3*. *PNC-Coor3* additionally coordinates *PNC3* on channels *Ch1* and *Ch2*.

A node which participates in a particular PNC can request this PNC and this node is most likely able to receive a PNC request when this PNC has been requested remotely by another node. In exceptional cases a node may be configured to request a particular PNC, but not receive a PNC request of the same PNC initiated remotely by another node. This is depicted in figure 5.40. *Node4* has the possibility to request *PNC3*. But a request of *PNC3* received by *PNC-Coor3* is not forward to *PNC-Coor3* on *Ch3*. And since *PNC-Coord2* does not handle *PNC3*, *Node4* will never receive a NM message where *PNC3* is requested. This could be used by a node to remotely request a PNC, but do not contribute to this PNC (see also section 5.4.1.3.3).

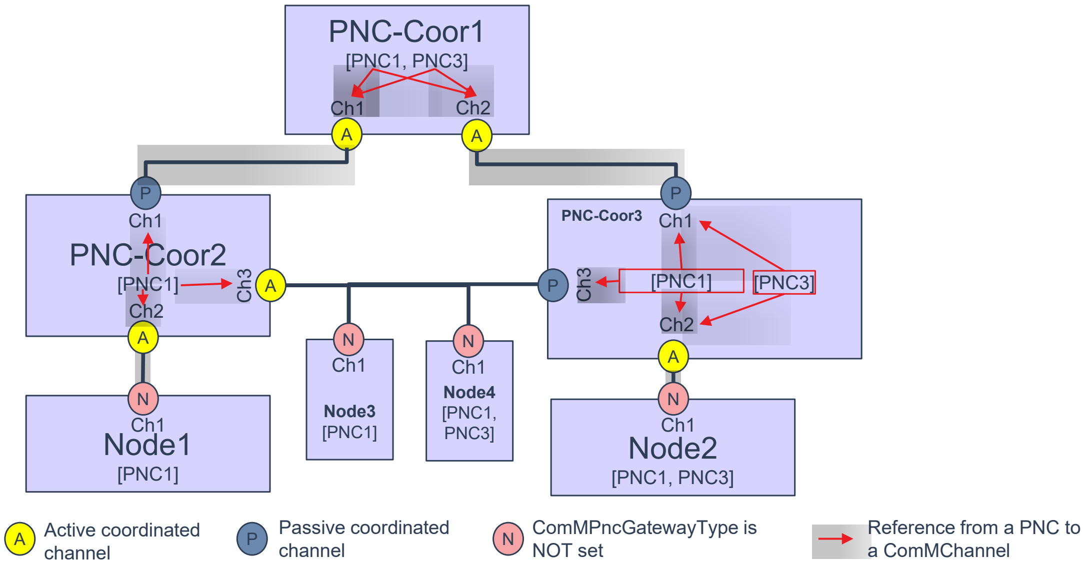

Figure 5.40: PNC topology example

5.4.1.3.1 Check for top level PNC-Coordinator

The definition of a top level PNC-Coordinator is essential for the check on cyclic PNC topologies. The cycle check and the top level PNC-Coordinator are considered per PNC:

For all nodes which have a specific PNC *X* configured, identify the nodes which have PNC coordination configured, with the PNC *X* only referencing channels with `CommunicationConnector.pncGatewayType` set to `active`.

Approach to check:

Create a list of which `EcuInstance`s a PNC *X* is assigned to, called "PNC to ECU mapping" by checking which PNCs are configured for each `EcuInstance` in the `System`.

Example of "PNC to ECU mapping" for figure 5.40:

- PNC1: {PNC-Coor1, PNC-Coor2, Node1, Node3, Node4, PNC-Coor3, Node2}
- PNC3: {PNC-Coor1, Node4, PNC-Coor3, Node2}

Identify the `EcuInstance`s which have PNC coordination enabled and PNC *X* only references channels with `CommunicationConnector.pncGatewayType` set to `active`.

In the example given in figure 5.40 the ECU *PNC-Coor1* is the top level PNC-Coordinator for both, *PNC1* and *PNC3*. But there may exist configurations where different ECUs are top level PNC-Coordinators for different PNCs or even multiple top level PNC-Coordinators for the same PNC. Please note, multiple top level PNC coordinators for the same PNC is only supported, if [constr_3714] is fulfilled.

[constr_3781] Each PNC assigned to multiple PhysicalChannels shall have a top level PNC-Coordinator

Imposition time: IT_SysDesc

⌈In a System, if a PNC is assigned to multiple PhysicalChannels according to [TPS_SYST_03080], then this PNC shall have at least one top level PNC-Coordinator according to [TPS_SYST_03082].⌋

For simple setups of partial networks, where PNCs are not distributed across multiple PhysicalChannels, no PNC-Coordinator is required.

[TPS_SYST_03082] Definition of top level PNC-Coordinator

Upstream requirements: RS_SYST_00042

⌈An EcuInstance is defined as top level PNC-Coordinator for a specific PNC if all involved PhysicalChannels (according to [TPS_SYST_03080]) only refer to CommunicationConnectors aggregated at that EcuInstance, where CommunicationConnector.pncGatewayType is set to active.⌋

[constr_3714] Multiple top level PNC-coordinators shall be allowed

Imposition time: IT_SysDesc

⌈Multiple top level PNC-coordinators shall only be allowed if no network path across all networks exist that connects a CommunicationConnector with pncGatewayType PncGatewayTypeEnum.active to another CommunicationConnector with pncGatewayType PncGatewayTypeEnum.active where both CommunicationConnectors belong to different top level PNC-coordinators.⌋

5.4.1.3.2 Check for cyclic PNC-Coordinator topology

The topology of a partial network cluster (PNC) needs to be cycle-free, that is, the tree spanning the PNC-Coordination needs to be an acyclic directed graph (ADG). Cycles in the graph could make releasing PNC requests impossible (deadlock). Having opposing directions of edges in the graph could cause a split in the PNC network.

The forwarding of PNC requests within an ECU is performed as follows:

- PNC requests received on a CommunicationConnector (channel) with CommunicationConnector.pncGatewayType set to active are forwarded to all CommunicationConnectors where this PNC is assigned to (according to [TPS_SYST_03080]) (this also includes the CommunicationConnector where the PNC request was received)
- PNC requests received on a CommunicationConnector (channel) with CommunicationConnector.pncGatewayType set to passive are forwarded to all CommunicationConnectors where this PNC is assigned to (according to

[TPS_SYST_03080]) and the CommunicationConnector.pncGatewayType is set to active

- in all other cases the PNC requests are NOT forwarded

Approach to check for cycles in PNC topology, needs to be checked for each PNC individually:

[TPS_SYST_03083] Creation of a *PNC paths tree*

Upstream requirements: RS_SYST_00042

⌈Beginning with the top level PNC-Coordinator of a specific PNC *X* ([TPS_SYST_03082]), iterate "depth first" over all channels where PNC *X* is assigned to (at each node reached only follow network links which have CommunicationConnector.pncGatewayType set to active), and build a tree of nodes reachable by the channels (PNC paths tree).⌋

By this, a tree of paths in the system is built. In case a node can reach itself again in a network subtree of its own channels, a cycle is detected and the topology is invalid.

Example PNC paths tree for figure 5.40:

PNC1:

- **PNC-Coor1**
  - Ch1 → *PNC-Coor2*
    - Ch2 → *Node1*
    - Ch3 → *Node3*
      - *Node4*
      - *PNC-Coor3*
        - Ch2 → *Node2*
  - Ch2 → *PNC-Coor3*
    - Ch2 → *Node2*

PNC3:

- ***PNC-Coor1***
  - Ch2 → *PNC-Coor3*
    - Ch2 → *Node2*

Figure 5.41: PNC Coordination tree example

In the example topology of figure 5.40 *PNC-Coor3* can be reached from top level PNC-Coordinator *PNC-Coor1* directly and via *PNC-Coor2* on different paths, but it cannot reach itself, so this is no issue (cycle).

[TPS_SYST_03084] Acyclic PNC graph definition ⌈For each PNC, the communication relations to aggregate and distribute the system's PNC state between all nodes, including PNC-Coordinators, shall form a topology reflecting a directed, acyclic graph (according to [TPS_SYST_03083]).⌋

The PNC topology depicted in figure 5.42 is an example where a cyclic dependency is defined.

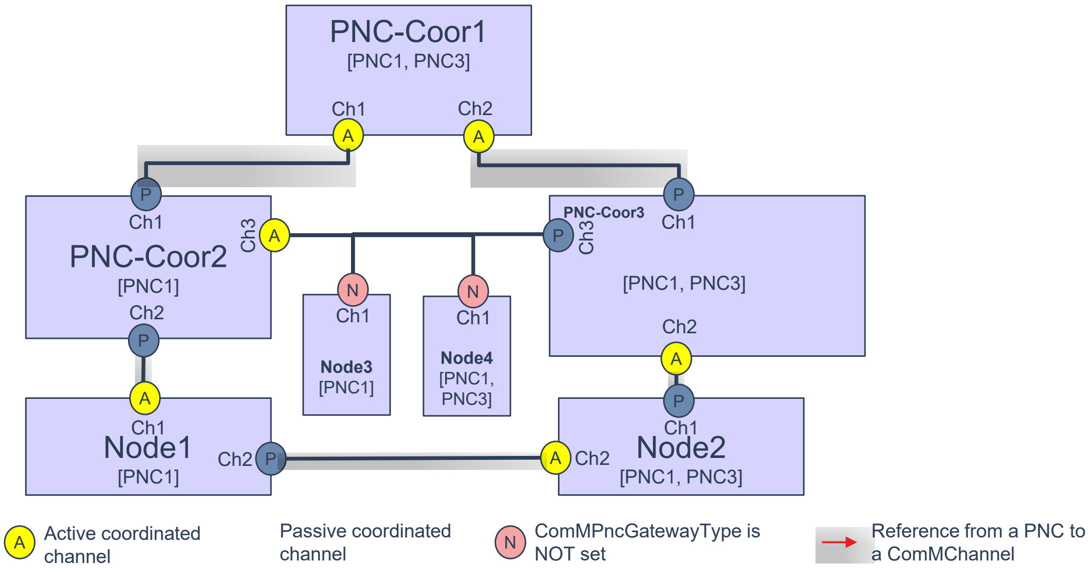

Figure 5.42: PNC topology example with cyclic graph error

Some constraints are fulfilled by this example, e.g. there in only one top level PNC-Coordinator defined (*PNC-Coor1*) according to [constr_3714], also [constr_5093] is fulfilled.

An issue arises with the cyclic definition of *PNC1* coordination between *PNC-Coor2*, *PNC-Coor3*, *Node2*, and *Node1*. This topology is invalid according to [TPS_SYST_03084].

PNC1:

- **PNC-Coor1**

Ch1 → *PNC-Coor2*
Ch2 → *Node1*
Ch3 → *Node3*
Node4
PNC-Coor3
Ch2 → *Node2*
Ch2 → *Node1*
Ch1 → *PNC-Coor2*

Ch2 → *PNC-Coor3*
Ch2 → *Node2*
Ch2 → *Node1*
Ch1 → *PNC-Coor2*
Ch3 → *PNC-Coor3*

Figure 5.43: PNC Coordination tree example with cycle

5.4.1.3.3 Optional check if all nodes are reachable from PNC-Coordinators

An additional check may compare if all nodes in the "EcuInstance inter-acts with PNC" list ([TPS_SYST_03081]) can be found in the "PNC paths tree"

([TPS_SYST_03083]). For each node which can be found in the "EcuInstance interacts with PNC", but not the "PNC paths tree", a warning shall be issued that this node can request a PNC, but can not be requested by that PNC.

The example in figure 5.40 illustrates that *Node4* is issuing PNC requests on *PNC3*, however in the "PNC paths tree" shown in figure 5.41 *Node4* does not occur in the tree for *PNC3*, thus *Node4* will not be requested by *PNC3*.

[advisory_02004] Check for reachable PNC nodes

Imposition time: IT_SysDesc

⌈If an EcuInstance is part of the "EcuInstance interacts with PNC" list ([TPS_SYST_03081]) for a particular PNC then this EcuInstance shall also appear in the "PNC paths tree" ([TPS_SYST_03083]) for that PNC.⌋

5.4.1.4 Dynamic Partial Network Cluster Mapping

In order to reduce the coding/adaptions-variants because of the wakeup-sleep-behavior (i.e. Function that transmits and receives PDUs mapped to PNCs can be deactivated/activated, placed on different ECUs or even run on Adaptive-AUTOSAR partitions) the PNC-to-channel-mapping table of the PNC Gateways can be dynamically reconfigured.

For this functionality, two parts of the PNC-to-channel-mapping need to exist:

- statically configured via SystemDescription and stored in ROM. This is used to define PNC routing for critical system communication (i.e. keep bus communication alive during hazard lights). This is also the default behavior when dynamic PNC-to-channel-mapping is not used or before this dynamic handling was introduced.
- configurable to be changed during runtime, stored in NVRAM. The Entries can be read and set (never unset) by a learning algorithm and via APIs. The table can also be reset by API, but it contains at least the entries out of the statically configured table.

	PN-Cluster 1	PN-Cluster 2	PN-Cluster 3	PN-Cluster 4	PN-Cluster 5	...	PN-Cluster N
Bus X	S	S					
Bus Y				S			
Bus Z							
Bus to other GwECU		S			S		
...							

	PN-Cluster 1	PN-Cluster 2	PN-Cluster 3	PN-Cluster 4	PN-Cluster 5	...	PN-Cluster N
Bus X	S	S	S				
Bus Y		L		S			
Bus Z			L				
Bus to other GwECU	L	S			S		
...							

Figure 5.44: Example for static and configurable PNC-to-channel-mapping

There are two different kinds of mapping table entries as shown in Figure 5.44.

- **Static PNC Mapping** (S): Entries in PNC-to-channel-mapping are defined in ARXML and stored in nonvolatile memory of the ECU.
- **Configurable PNC Mapping** (L): Entries in PNC-to-channel-mapping can be added dynamically via PNC learning mechanism but can also be reset.

Mappings can only be added to already existing PNCs. New PNCs cannot be introduced dynamically, but it shall be possible to have PNCs available even without existing mapping/actual usage. Note that even if a PNC has at least one static relation it is still learnable to additional channel relations.

“Static” entries of the PNC-to-channel-mapping (black “S” in Figure 5.44) can be defined via the `PncMapping` attributes `pncGroup`, `wakeupFrame` or `physicalChannel`.

If a PNC has no “static” mapping and therefore no entries within the PNC-to-channel-mapping, but entries shall be learnable (blue “L” in Figure 5.44), even if there is no Tx-/Rx-Relation to the Gateway running the PNC Gateway, then the PNC could be defined in System Description via the PncMapping attributes relevantForDynamicPncMapping or dynamicPncMappingPduGroup.

Note: Defining such dynamic PNC-to-channel-mapping entries makes only sense if the PNC is assigned to a CommunicationConnector where dynamicPncToChannelMappingEnabled is set to TRUE. Otherwise those dynamic mappings will not be handled by the ECU on this channel. Learning of dynamic PNC-to-channel-mapping is started by an explicit trigger. The node that starts this algorithm sends a Partial Network Learning request, which is then responded by all nodes with their current PNC Membership. PNC Gateways will forward this request to other channels. During this learning phase the PNC Gateway observes all responses and updates the PNC-to-channel-mapping accordingly, depending on which channels a PNC member was observed/received.

Note: While the PNC-to-channel-mapping could be dynamically re-configured, all routing paths (including source and target I-PDUs) within a Gateway are still configured statically. Therefore it is expected that the design of the SystemDescription ensure that all routing paths of all potentially expected PNC-to-channel-mappings are provided statically. For this dynamic PNC-to-channel-mapping some configurations restrictions and design limitations are needed to ensure proper functionality. These are provided in the following either as constraints or as text if a constraint is not feasible.

[constr_5167] pncGatewayType and ECU over the whole system

Imposition time: IT_SysDesc

⌈Only one PNC Gateway ECU in the whole System shall exist that sets on all its CommunicationConnectors the pncGatewayType to active.⌋

This constraint ensures that only one PNC coordinator in the partial network exists where all its CommunicationConnectors have pncGatewayType set to active.

[constr_5168] pncGatewayType passive and connected ECUs

Imposition time: IT_SysDesc

⌈For all CommunicationConnectors with pncGatewayType set to passive belonging to one PNC Gateway ECU, all connected counterpart CommunicationConnectors, where pncGatewaypncGatewayTypeType is set to active shall belong to one ECU, if dynamicPncToChannelMappingEnabled is set to TRUE for at least one of the affected CommunicationConnectors.⌋

This constraint ensures that one ECU cannot be passively connected to two different coordinators. This avoids coordination problems in normal systems as there is no coordination from passive to passive. For dynamic PNC-to-channel mapping it is essential to avoid cycles in the forwarding of the learning request.

[constr_5170] nmPassiveModeEnabled and dynamicPncToChannelMappingEnabled

Imposition time: IT_SysDesc

⌈If nmPassiveModeEnabled is set to TRUE on a NmNode then dynamicPncToChannelMappingEnabled shall be set to FALSE on the according CommunicationConnector referring to the same CommunicationController.⌋

Note: A passive NM node cannot transmit its cluster membership to the Gateway. Therefore, it cannot take part at the dynamic PNC learning and all assigned PNCs have to be statically configured, i.e. no dynamic mapping is allowed.

Additionally this constraint also leads to the fact that defining dynamic mappings for such a NmNode makes no sense as they will be ignored. The CanCommunicationConnector.pncWakeupDataMask of the Gateways have to consider learnable PNCs.

In a system with multiple (cascaded) Gateways, the RepeatMessage time has to be sufficient to fulfill its purpose and provide enough time for PNC Learning mechanism to receive at least one NM PDU of all NmNodes.

5.4.2 Com Management Mapping

The AUTOSAR BSW stack supports the configuration of the ComM module which encapsulates the control of the underlying communication services. The ComM module collects the bus communication access requests from communication requestors and coordinates the bus communication access requests. In order to utilize the communication requests from application software the Software Component Template supports the definition of PortGroups with the category MODE_MANAGEMENT. In this section it is described how PortGroups with the category MODE_MANAGEMENT are mapped to communication channels.

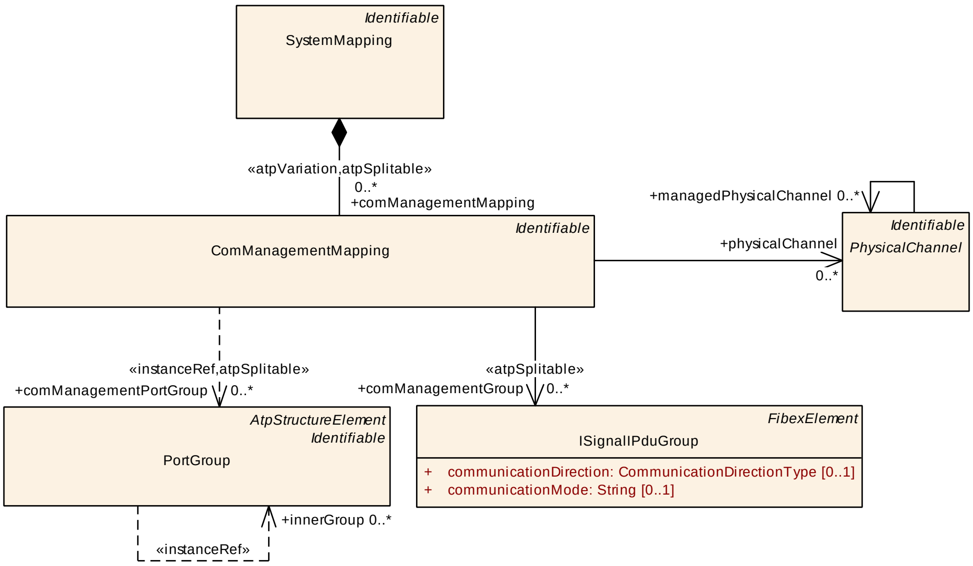

Figure 5.45: Mapping between PortGroups and communication channels

5.6 Dds Mapping

In AUTOSAR CP, a DDS Topic can ba associated to an ISignal. To map such an association, the DdsCpISignalToDdsTopicMapping is used, that maps an ISignal to one DdsCpTopic.

It is possible to have multiple scenarios that combine one or more DdsCpTopics mapped to one or more ISignals. In the following paragraphs, an explanation of each scenario is given:

- **(1:1): One `ISignal` mapped to One `DdsCpTopic`:**

  In this scenario, a single DdsCpISignalToDdsTopicMapping represents a unique linkage between an AUTOSAR ISignal and a DdsCpTopic in the context of a DdsCpDomain and one or more DdsCpPartitions within it. S/R ports connected to such ISignal will have their I/O operations connected to a DDS DataWriter or DataReader entity suitable for accessing the DDS Topic Type, name, Domain, Partition and QoS policies specified directly or indirectly by the referenced DdsCpTopic.

- **(1:N): One `ISignal` to Multiple `DdsCpTopic`s (DDS FAN-OUT):**

  In this scenario, multiple DdsCpISignalToDdsTopicMapping elements represent a linkage between one AUTOSAR ISignal and multiple DdsCpTopics within one or more DdsCpDomains and one or more DdsCpPartitions within them. S/R Ports connected to such ISignal will have their I/O operations connected to multiple DDS DataWriter or DataReader entities suitable for accessing the DDS Topic Types, names, Domains, Partitions and QoS policies specified directly or indirectly by the referenced DdsCpTopics. Example use cases might be:

  - Propagating a signal in multiple DDS Domains and/or DDS Partitions
  - Propagating a signal under multiple QoS profiles
  - Propagating a single under multiple DDS Topic names

  In the picture below an example of 1:N mapping is shown:

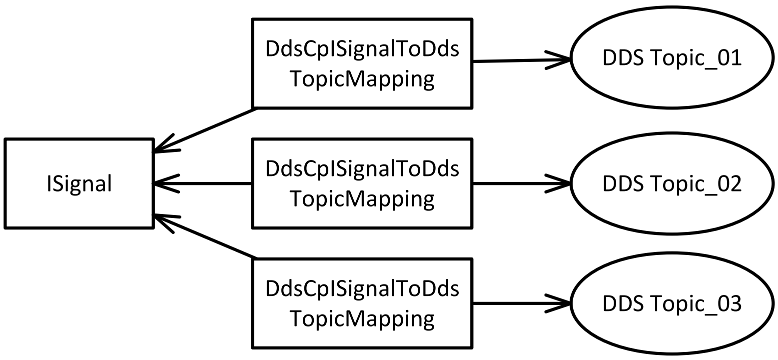

Figure 5.52: One ISignal mapped to more than one DDS Topic

- **(N:1): Multiple `ISignal`s to One `DdsCpTopic`:**

  In this scenario, multiple DdsCpISignalToDdsTopicMapping elements represent a linkage between several AUTOSAR ISignals and a single DdsCpTopic in the context of a DdsCpDomain and one or more DdsCpPartitions within it. S/R Ports connected to such ISignals will have their I/O operations connected to a DDS DataWriter or DataReader entity suitable for accessing the DDS Topic

Type, name, Domain, Partition and QoS policies specified directly or indirectly by the referenced DdsCpTopic. Example use cases might be:

– Consolidating multiple Elements from different PortInterfaces, realised in multiple PortPrototypes, into a single DDS Topic

In the picture below an example of N:1 mapping is shown:

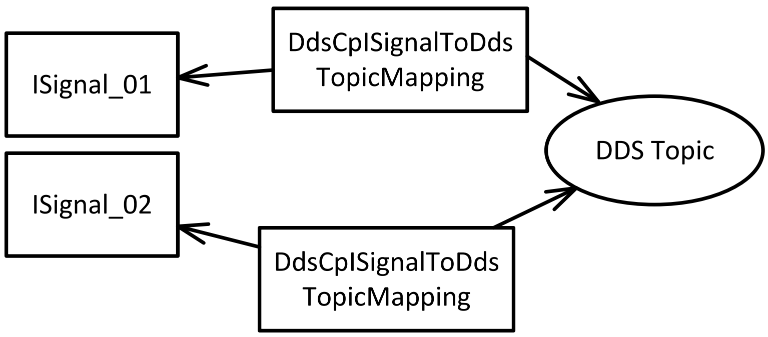

Figure 5.53: One DDS Topic mapped by more than one ISignal

- **(N:M) Multiple ISignals to Multiple DdsCpTopics:**

  In this scenario, multiple DdsCpISignalToDdsTopicMapping elements represent a linkage between several AUTOSAR ISignals and several DdsCpTopics within one or more DdsCpDomains and one or more DdsCpPartitions within each of them. S/R Ports connected to such ISignals will have their I/O operations connected to multiple DDS DataWriter or DataReader entities suitable for accessing the DDS Topic Types, names, Domains, Partitions and QoS policies specified directly or indirectly by the referenced DdsCpTopics. Example use cases might be:

  – Propagating a signal in multiple DDS Domains and/or DDS Partitions

  – Propagating a signal under multiple QoS profiles

  – Propagating a single under multiple DDS Topic names

  – Consolidating multiple Elements from different PortInterfaces, realised in multiple PortPrototypes into a single DDS Topic

To model each of such scenario, the generic multiplicity N:M is used. It is possible to configure the actual multiplicity according the desired use-case.

Note: Since a Dds Topic is strictly related to the data type it deals with, while configuring the user shall allow different ISignals sharing the same DDS Topic only if the ISignals are related to the same data type.

The picture below shows the architecture of DdsCpISignalToDdsTopicMapping.

6 Communication

This chapter describes all topics that deal with constraints or configurations that describe the information exchange between the ECUs. The description of communication matrices in the System Template is based on the description in ASAM FIBEX [8]. Because of the requirements of AUTOSAR some extensions were made to the original FIBEX model.

The main elements to describe communication in the System Template are SystemSignals, ISignals, Pdus and Frames, as it can be seen on Figure 6.1.

Frames can be defined independently of communication clusters. On the communication channel the Frame is represented by the referencing FrameTriggering.

A Frame has a payload section of a certain length in bytes, which contains an arbitrary number of non-overlapping Pdus. In AUTOSAR only FlexRay supports the packing and unpacking of multiple Pdus into/out of one FlexRay Frame. The AUTOSAR CanIf and LinIf are not capable of packing multiple Pdus into one Frame.

[constr_3036] Pdus in CAN and LIN Frames

Imposition time: IT_SysDesc

⌈CAN Frames and LIN Frames shall only contain one Pdu.⌋

Note that via the ContainerIPdu it is possible to transport several IPdus in one ContainerIPdu in order to support CAN FD.

A Pdu (Protocol Data Unit) is the information delivered through a network layer. For the network to understand which layer is being discussed, a single-letter prefix is added to the PDU.

- IPdu - Interaction Layer Protocol Data Unit (assembled and disassembled in Com). In the case of external communication the Interaction Layer packs one or more signals into assigned IPdus and passes them to the underlying layer for transfer between nodes in a network.
- NPdu - Network Layer Protocol Data Unit (assembled and disassembled in a Transport Protocol module). The TP module's main purpose is the segmentation and reassembly of IPdus that do not fit in one of the assigned NPdus.
- LPdu - Data Link Layer Protocol Data Unit (assembled and disassembled in AUTOSAR Hardware Abstraction layer). The element Frame in the System Template represents the AUTOSAR Layered Architectures LSdu. Sdu is the abbreviation of "Service Data Unit". The Data Link Layers LPdu contains the LSdu and PCI (Protocol Control Information). The LPdu is not described in the System Template.

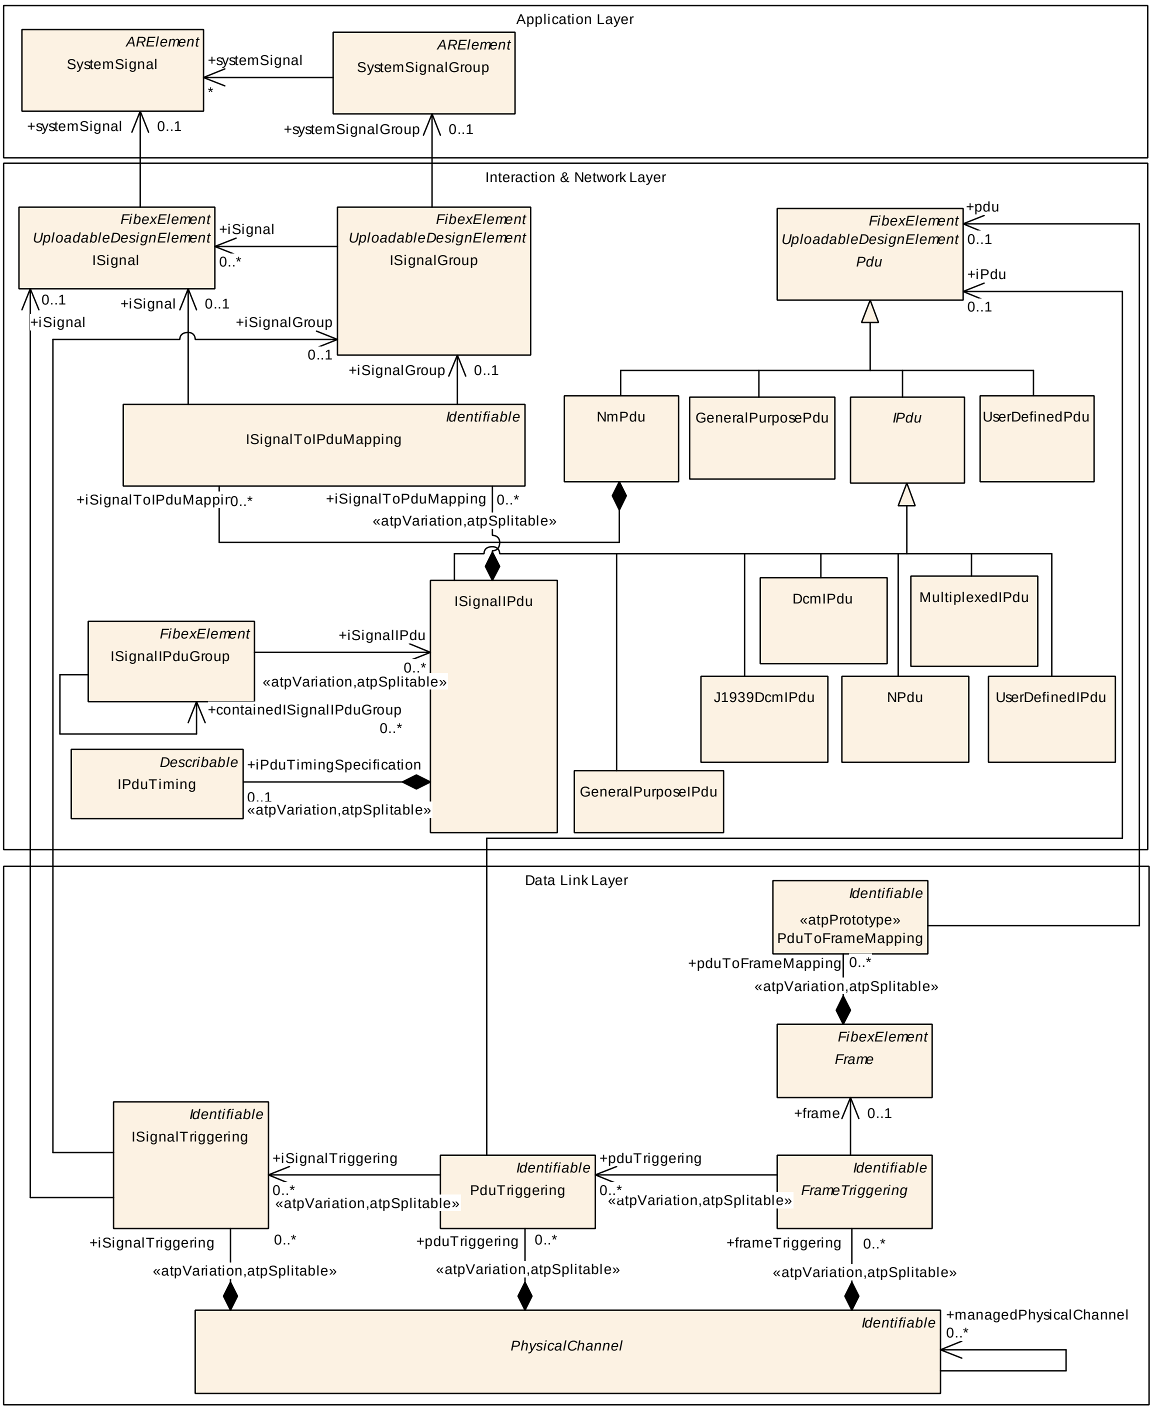

Figure 6.1: Communication Overview (FibexCore: Communication)

In case no multiplexing is performed the IPdus of Com that fit into one frame can be passed directly via the PDU Router to the communication interfaces.

[constr_3037] maximum Frame frameLength for CAN and LIN

Imposition time: IT_SysDesc

⌈For CAN and LIN the maximum frameLength is 8 bytes and 64 bytes in case of CAN FD.⌋

[constr_3038] maximum Frame frameLength for FlexRay

Imposition time: IT_SysDesc

⌈For FlexRay the maximum frameLength is 254 bytes.⌋

[TPS_SYST_01048] Handling of large IPdus ⌈Large IPdus that are too long to fit into one Frame of the respective subclass of CommunicationCluster shall be routed via a Transport Protocol to the communication interfaces.⌋

For example an IPdu with the length of 10 bytes needs to be routed via a Transport Protocol on CAN but on FlexRay this is not required.

The Transport Protocols are described in more detail in chapter 6.8.

If multiplexing is performed an IPdu is routed between the IPdu Multiplexer and the Interface Layer or Transport Layer. To distinguish these two different cases two specializations ISignalIPdu and MultiplexedIPdu are introduced. A ISignalIPdu represents an IPdu handled by AUTOSAR Com. The AUTOSAR IPduM is responsible to combine Com ISignalIPdus to MultiplexedIPdus. On receiver-side the IPduM is responsible to interpret the content of MultiplexedIPdus and provide Com separated ISignalIPdus by taking into account the value of the selector field. The IPdu Multiplexer is described in more detail in chapter 6.5.

AUTOSAR Com provides the possibility to define Transmission Modes for each Com ISignalIPdu. For this reason the ISignalIPdu aggregates the IPduTiming. The Transmission Modes are described in more detail in chapter 6.4.

6.1 Triggerings and Ports

The elements FrameTriggering, PduTriggering and ISignalTriggering are describing the usage of Frames, IPdus and ISignals on a PhysicalChannel.

A FrameTriggering need to fulfill requirements for contained Pdus that are defined by the corresponding PduTriggerings. And the PduTriggering need to fulfill requirements for contained ISignals that are defined by the corresponding ISignalTriggerings. The references between the Triggering elements can be used to describe these relationships. More details can be found in class tables of FrameTriggering, PduTriggering and ISignalTriggering.

In AUTOSAR the timing of bus messages can be controlled by send requests of the Application layer in combination with the Com Transmission Modes and Transfer Properties (esp. CAN). On the other hand it can be controlled by the FlexRay or LIN Interface. In this case the Bus Interface only requests IPdus that have to be provided by Com.

In the System Template the Com controlled timing is described with the aggregation between the ISignalIPdu and the IPduTiming. The LIN and FlexRay Scheduling Tables are described in the FrameTriggering.

Timing requirements for FlexRay, TTCAN and LIN Pdus can be specified with the Timing Extension model. More details are described in chapter 1.4.3.

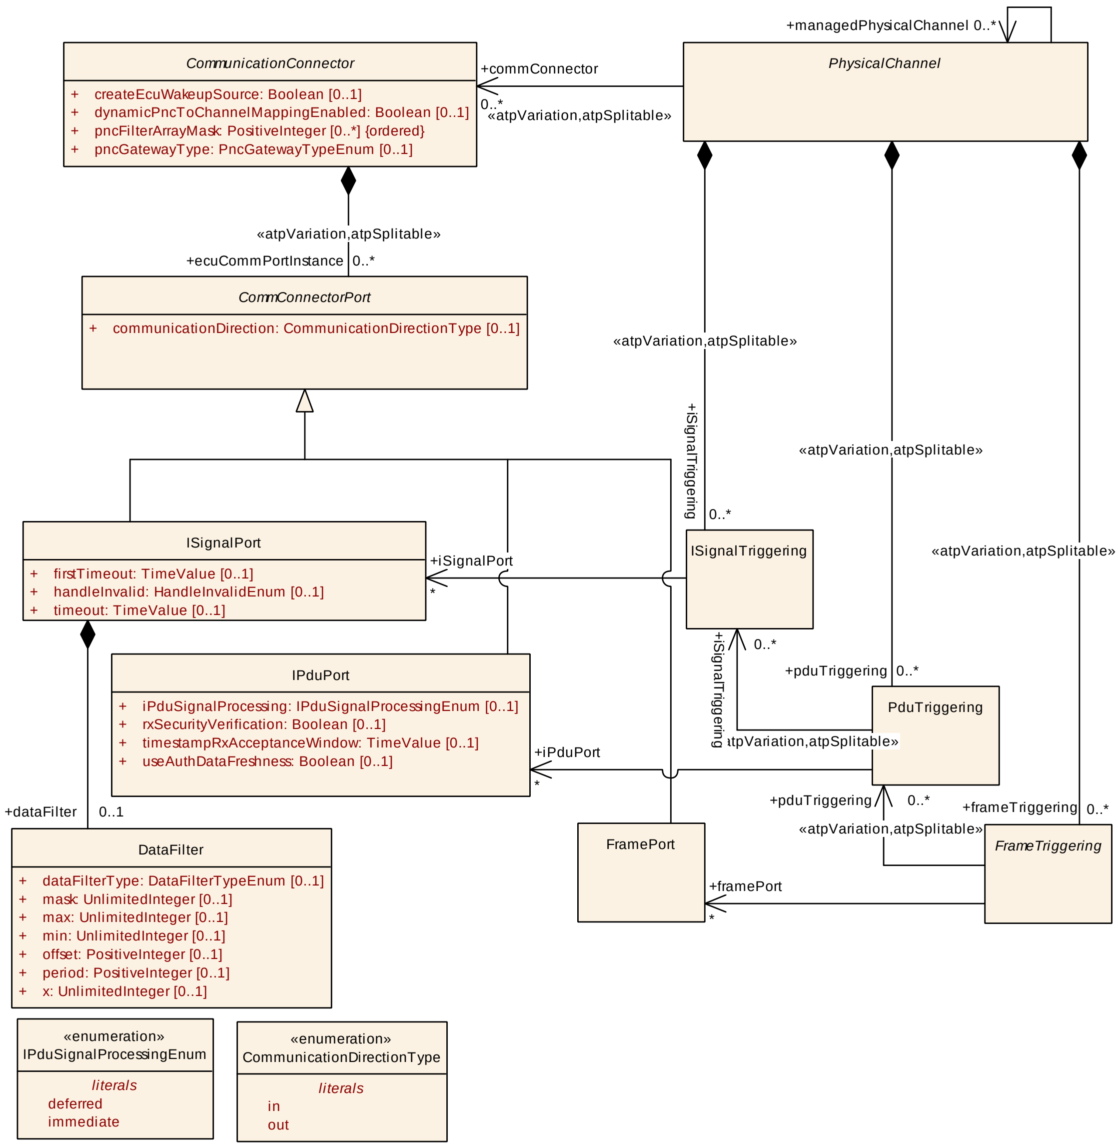

Figure 6.2: Communication Matrix (FibexCore: CommunicationMatrix)

Figure 6.2 shows the relationship between the CommConnectorPort and the FrameTriggering, PduTriggering and ISignalTriggering. This relationship allows to specify explicitly which Frames, Pdus, ISignals are received/sent by the connected ECU on the connected channel.

[constr_3243] FrameTriggering.pduTriggering condition

Imposition time: IT_SysDesc

⌈A FrameTriggering shall reference a PduTriggering if the PduTriggering references a Pdu that is referenced by a PduToFrameMapping which in turn is aggregated by the Frame that is referenced by that FrameTriggering.⌋

[constr_3250] PduTriggering.iSignalTriggering condition

Imposition time: IT_SysDesc

⌈A PduTriggering shall reference an ISignalTriggering if the ISignalTriggering references an ISignal or an ISignalGroup that is referenced by an ISignalToIPduMapping which in turn is aggregated by the Pdu that is referenced by that PduTriggering.⌋

[TPS_SYST_02102] FrameTriggering.pduTriggering references that shall be ignored ⌈References from FrameTriggering to PduTriggering which are not covered by [constr_3243] shall be ignored.⌋

As a consequence of [constr_3243] the following implications can be derived:

- The PduTriggering of the ContainerIPdu is referenced from the FrameTriggering but the PduTriggerings of the contained IPdus are not referenced from the FrameTriggering.
- The PduTriggering of the MultiplexedIPdu is referenced from the FrameTriggering but the PduTriggerings of the multiplexed Part Pdus are not referenced from the FrameTriggering.

[TPS_SYST_02104] Triggerings on PhysicalChannel ⌈The following modeling creates a "membership" of ISignals, ISignalGroups, Pdus, and Frames in a given PhysicalChannel:

- PhysicalChannel aggregates
  - ISignalTriggering that in turn references ISignal in the role iSignal
  - ISignalTriggering that in turn references an ISignalGroup in the role iSignalGroup ([constr_5106] applies).
- PhysicalChannel aggregates PduTriggering that in turn references a Pdu in the role iPdu.
- PhysicalChannel aggregates FrameTriggering that in turn references a Frame in the role frame.

⌋

[constr_5106] ISignalGroup and ISignal referenced from ISignalTriggering

Imposition time: IT_SysDesc

⌈Either an ISignalGroup and all ISignals referenced from the ISignalGroup are also referenced from ISignalTriggerings aggregated at the same PhysicalChannel or neither the ISignalGroup nor any of the ISignals referenced by the ISignalGroup shall be referenced from ISignalTriggerings.⌋

[TPS_SYST_01142] Rules for the creation of references to Ports (ecuCommPortInstance) with communicationDirection out on sending Ecu ⌈

- Application sends ISignal or ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup members that are sent by the Application.
  - PduTriggering reference to IPduPort shall be created
  - FrameTriggering reference to FramePort shall be created
- COM Signal Gateway
  - Reference from ISignalTriggering to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup
  - Reference from ISignalTriggering to ISignalPort for a subset of ISignals inside the ISignalGroup shall be created (in case not all members of the ISignalGroup participate in the target Signal Gateway relation).
  - PduTriggering reference to IPduPort shall be created
  - FrameTriggering reference to FramePort shall be created
- ISignal or ISignalGroup is mapped to ISignalIPdu but NOT sent by Application or Signal Gateway
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup

- No ISignalTriggering reference to ISignalPort shall be created for an ISignalGroup
- No ISignalTriggering reference to ISignalPort shall be created for any ISignal that is part of an ISignalGroup
- PduTriggering reference to IPduPort shall be created
- FrameTriggering reference to FramePort shall be created

- Neither ISignal, ISignalGroup, Pdu, nor Frame sent by the ECU
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for any ISignal that is part of an ISignalGroup
  - No PduTriggering reference to IPduPort shall be created
  - No FrameTriggering reference to FramePort shall be created

⌋

Please note that it is possible to configure a signal that is transmitted by an application and also routed by a SignalGateway. At runtime it has to be ensured that only one path is active at a particular point in time (to avoid race conditions in COM Stack).

[TPS_SYST_02106] Rules for the creation of references to Ports (ecuCommPortInstance) with communicationDirection in on receiving Ecu ⌈

- Application receives ISignal or ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup
  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup members that are received by the Application.
  - PduTriggering reference to IPduPort shall be created
  - FrameTriggering reference to FramePort shall be created
- COM Signal Gateway
  - Reference from ISignalTriggering to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup

  - Reference from ISignalTriggering to ISignalPort shall be created for the ISignalGroup
  - Reference from ISignalTriggering to ISignalPort for a subset of ISignals inside the ISignalGroup shall be created (in case not all members of the ISignalGroup participate in the source Signal Gateway relation).
  - PduTriggering reference to IPduPort shall be created
  - FrameTriggering reference to FramePort shall be created
- ISignal or ISignalGroup is mapped to ISignalIPdu but NOT received by Application or Signal Gateway
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for any ISignal that is part of an ISignalGroup
  - PduTriggering reference to IPduPort shall be created
  - FrameTriggering reference to FramePort shall be created
- Neither ISignal, ISignalGroup, Pdu, nor Frame received by the ECU
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignal that is not part of an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for an ISignalGroup
  - No ISignalTriggering reference to ISignalPort shall be created for any ISignal that is part of an ISignalGroup
  - No PduTriggering reference to IPduPort shall be created
  - No FrameTriggering reference to FramePort shall be created

⌋

[constr_3252] ISignalTriggering.iSignalPort reference condition

Imposition time: IT_SysDesc

⌈An ISignalTriggering shall only reference an ISignalPort if the CommunicationConnector aggregating that ISignalPort is referenced by the PhysicalChannel which in turn aggregates that ISignalTriggering.⌋

[constr_3253] PduTriggering.iPduPort reference condition

Imposition time: IT_SysDesc

⌈A PduTriggering shall only reference an IPduPort if the CommunicationConnector aggregating that IPduPort is referenced by the PhysicalChannel which in turn aggregates that PduTriggering.⌋

[constr_3254] FrameTriggering.framePort reference condition

Imposition time: IT_SysDesc

⌈A FrameTriggering shall only reference a FramePort if the CommunicationConnector aggregating that FramePort is referenced by the PhysicalChannel which in turn aggregates that FrameTriggering.⌋

[constr_3255] FrameTriggering.pduTriggering reference condition with regard to the PhysicalChannel

Imposition time: IT_SysDesc

⌈A FrameTriggering shall only reference a PduTriggering in the role pduTriggering if both the FrameTriggering and PduTriggering are aggregated by the same PhysicalChannel.⌋

[constr_3256] PduTriggering.iSignalTriggering reference condition with regard to the PhysicalChannel

Imposition time: IT_SysDesc

⌈A PduTriggering shall only reference an ISignalTriggering in the role iSignalTriggering if both the PduTriggering and ISignalTriggering are aggregated by the same PhysicalChannel.⌋

The following rules apply for the creation of PduTriggerings and IPduPorts:

- **[TPS_SYST_01052] Routing of UserDefinedPdus, NmPdus, NPdus** ⌈UserDefinedPdus, NmPdus, NPdus which are not going through the Pdu Router get their triggering information via the containing FrameTriggering and FramePort (no PduTriggering is defined for these Pdus).⌋

- **[TPS_SYST_03021] Routing of GeneralPurposePdus with category GLOBAL_TIME** ⌈GeneralPurposePdus with category GLOBAL_TIME shall have PduTriggering and IPduPorts defined.⌋

- **[TPS_SYST_02091] Routing of GeneralPurposePdus with category SD and GeneralPurposePdus with category DoIP** ⌈GeneralPurposePdus with category SD and GeneralPurposePdus with category DoIP shall have PduTriggering and IPduPorts defined since no Frames and FrameTriggerings are defined for Pdus that are handled by the SoAd.⌋

- **[TPS_SYST_01053] Low-level routing of NPdus** ⌈In case of a low-level routing of NPdus the Pdus are handled like IPdus and the PduTriggering and IPduPort shall be defined.⌋

- **[TPS_SYST_01138] Low-level routing of XcpPdus** ⌈Low-level routing of GeneralPurposeIPdus with category XCP: In case of a low-level routing of GeneralPurposeIPdus with category XCP the Pdus are handled like IPdus and the PduTriggering and IPduPort shall be defined.⌋

- **[TPS_SYST_01054] Routing of DcmIPdus** ⌈DcmIPdus shall have PduTriggering and IPduPorts since they are handled by the PduR (connection to the Dcm and/or DcmIPdu-routing).⌋

- **[TPS_SYST_01055] Routing of ISignalIPdus that are part of a MultiplexedIPdu** ⌈ISignalIPdus that are part of a MultiplexedIPdu (static or dynamic) and are also handled by the Com module shall have a PduTriggering and IPduPorts since they are handled by the PduR (and Com). Especially it is allowed to ignore certain received parts of a MultiplexedIPdu in a specific ECU.⌋

- **[TPS_SYST_01056] Routing of ISignalIPdus, UserDefinedIPdus, MultiplexedIPdus, GeneralPurposeIPdus, ContainerIPdus**

  Upstream requirements: RS_SYST_00055

  ⌈ISignalIPdus (not part of MultiplexedIPdus), UserDefinedIPdus, MultiplexedIPdus, GeneralPurposeIPdus and ContainerIPdus shall have a PduTriggering and IPduPort if they are handled by the PduR. Especially it is allowed to ignore a certain IPdu out of a Flexray frame if it is not considered in a specific ECU.⌋

- **[TPS_SYST_01057] Routing of NmPdus** ⌈If an NmPdu contains user data defined via the existence of NmPdu.iSignalToIPduMapping and is consequently handled via the PduR and Com the NmPdu shall also be referenced by a corresponding PduTriggering where attribute iPduPort exists accordingly.⌋

- **[TPS_SYST_02059] Routing of SecuredIPdus**

  Upstream requirements: RS_SYST_00054

  ⌈SecuredIPdus shall have a PduTriggering and IPduPort defined since they are handled by the PduR. Pdus that are part of a SecuredIPdu and are also handled by the Com module shall have a PduTriggering and IPduPorts since they are handled by the PduR (and Com).⌋

- **[TPS_SYST_02061] Routing of IPdus that are part of a ContainerIPdu**

  Upstream requirements: RS_SYST_00055

  ⌈IPdus that are part of a ContainerIPdu shall have a PduTriggering and IPduPorts since they are handled by the PduR.⌋

The following rule applies to the creation of ISignalTriggering and ISignalPort:

[TPS_SYST_01058] Pdu Gateway where an Ecu only routes a PduTriggering without being interested in the content ⌈In case of a Pdu Gateway where an Ecu only routes a PduTriggering without being interested in the content, the reference between the ISignalTriggerings (that are referred to by the PduTriggering in the role iSignalTriggering) and the respective ISignalPorts shall not be created.⌋

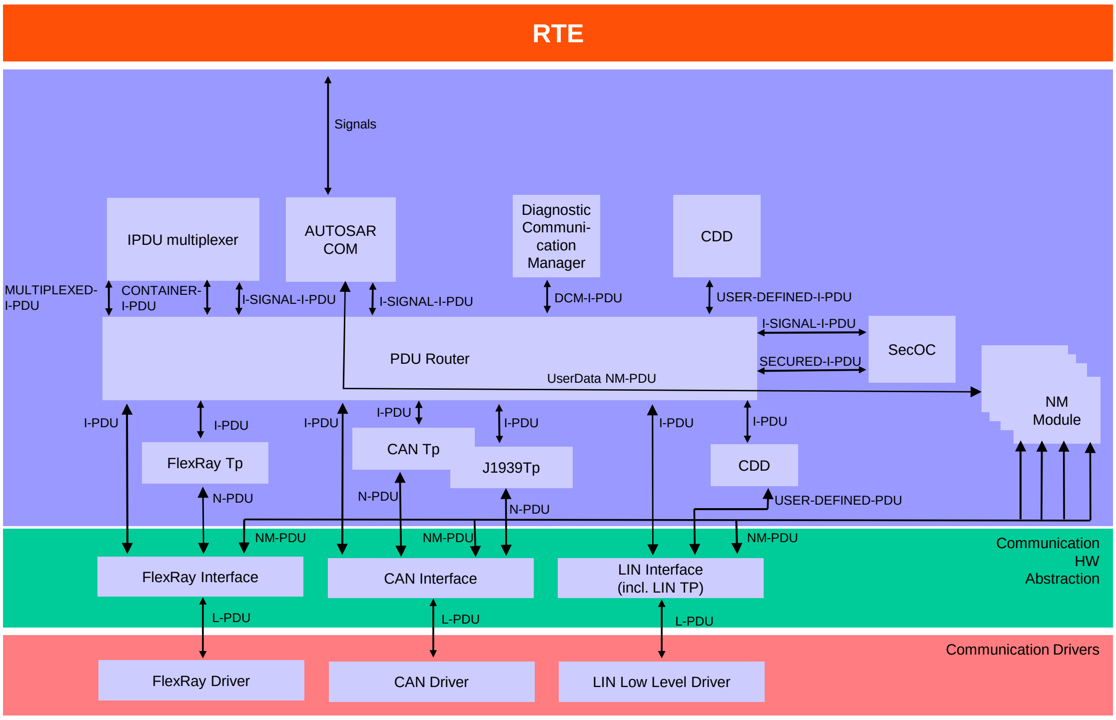

Figure 6.3: AUTOSAR Layered Architecture

Class	***CommConnectorPort*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreTopology			
Note	The Ecu communication relationship defines which signals, Pdus and frames are actually received and transmitted by this ECU. For each signal, Pdu or Frame that is transmitted or received and used by the Ecu an association between an ISignalPort, IPduPort or FramePort with the corresponding Triggering shall be created. An ISignalPort shall be created only if the corresponding signal is handled by COM (RTE or Signal Gateway). If a Pdu Gateway ECU only routes the Pdu without being interested in the content only a FramePort and an IPduPort needs to be created.

Note	Definition of signal processing modes.
Aggregated by	IPduPort.iPduSignalProcessing
Literal	*Description*
deferred	The signal indications / confirmations are deferred. **Tags:** atp.EnumerationLiteralIndex=0
immediate	The signal indications / confirmations are performed. **Tags:** atp.EnumerationLiteralIndex=1

Table 6.4: IPduSignalProcessingEnum

Class	**ISignalPort**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	Connectors reception or send port on the referenced channel referenced by an ISignalTriggering. If different timeouts or DataFilters for ISignals need to be specified several ISignalPorts may be created.			
Base	*ARObject*, *CommConnectorPort*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	*CommunicationConnector*.ecuCommPortInstance			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
dataFilter	DataFilter	0..1	aggr	Optional specification of a signal COM filter at the receiver side in case that the System Description doesn't use a complete Software Component Description (VFB View). This supports the inclusion of legacy system signals. If a full DataMapping exist for the SystemSignal this information may be available from a configured ReceiverComSpec. In this case the ReceiverComSpec overrides this optional specification.
ddsQosProfile	DdsCpQosProfile	0..1	ref	Reference to the DDS Qos profile used for this ISignal. **Tags:** atp.Status=candidate
firstTimeout	TimeValue	0..1	attr	• ISignalPort with communicationDirection = in: Optional first timeout value in seconds for the reception of the ISignal. • ISignalPort with communicationDirection = out: Optional first timeout value in seconds for transmission deadline monitoring.

▽

△

Class	**ISignalPort**			
handleInvalid	HandleInvalidEnum	0..1	attr	This attribute defines how invalidation is applied to the ISignals received in the context of this ISignalPort.
timeout	TimeValue	0..1	attr	• ISignalPort with communicationDirection = in: Optional timeout value in seconds for the reception of the ISignal. The attribute value is used to configure the Com Timeout in the COM module. The RTE ignores this attribute. The timeout can also be specified with the NonqueuedReceiverComSpec.aliveTimeout attribute. If a full DataMapping exists for the SystemSignal and the value is available in the configured ReceiverComSpec, then the timeout value in the ReceiverComSpec overrides this optional timeout specification during the creation of the Base Ecu Configuration of the COM module. • ISignalPort with communicationDirection = out: Optional timeout value in seconds for the transmission of the ISignal. The attribute value is used to configure the ComTimeout in the COM module. The RTE ignores this attribute. The timeout can also be specified with the ender ComSpec.transmissionAcknowledge.timeout attribute. If a full DataMapping exists for the SystemSignal and the value is available in the configured SenderComSpec, then the timeout value in the SenderComSpec overrides this optional timeout specification during the creation of the Base Ecu Configuration of the COM module. This attribute can be used in the following cases: • legacy signal where the System Description doesn't use a complete Software Component Description (VFB View) and where the DataMapping is missing. • bus monitoring use cases in which the DataMapping is ignored.

Note	Strategies of handling the reception of invalidValue.
Aggregated by	InvalidationPolicy.handleInvalid, ISignalPort.handleInvalid
Literal	*Description*
dontInvalidate	Invalidation is switched off. **Tags:** atp.EnumerationLiteralIndex=0
external Replacement	Replace a received invalidValue. The replacement value is sourced from the aggregation in the role replaceWith. **Tags:** atp.EnumerationLiteralIndex=1
keep	The application software is supposed to handle signal invalidation on RTE API level either by Data ReceiveErrorEvent or check of error code on read access. **Tags:** atp.EnumerationLiteralIndex=2
replace	Replace a received invalidValue. The replacement value is specified by the initValue. **Tags:** atp.EnumerationLiteralIndex=3

Table 6.6: HandleInvalidEnum

[TPS_SYST_01059] Relationship between FrameTriggering and CommConnectorPort ⌈For the reference between FrameTriggering and FramePort two approaches are supported:

- One to One relationship between FrameTriggering and FramePort per EcuInstance
- One FramePort per communicationDirection per EcuInstance exists and is referenced by all applicable FrameTriggerings (n to 1).

⌋

[TPS_SYST_01060] Relationship between PduTriggering and CommConnectorPort ⌈For the reference between PduTriggering and IPduPort two approaches are supported:

- One to One relationship between PduTriggering and IPduPort per EcuInstance
- One IPduPort per communicationDirection per EcuInstance exists and is referenced by all applicable PduTriggerings (n to 1).

⌋

[TPS_SYST_01061] Relationship between ISignalTriggering and CommConnectorPort ⌈For the reference between ISignalTriggering and ISignalPort two approaches are supported:

- One to One relationship between ISignalTriggering and ISignalPort per EcuInstance
- One ISignalPort per communicationDirection per timeout per EcuInstance exists and is referenced by all applicable PduTriggerings (n to 1).

⌋

[TPS_SYST_02208] ISignalPort.handleInvalid defines the reception invalidation behavior ⌈The attribute ISignalPort.handleInvalid defines the behavior during signal reception if the respective ISignal's invalidValue is received. The ISignal is assigned to this ISignalPort via the ISignalTriggering.⌋

[TPS_SYST_02209] Not defined ISignalPort.handleInvalid behavior ⌈If the attribute ISignalPort.handleInvalid is not defined then the value dontInvalidate shall be assumed.⌋

[constr_5053] Existence of ISignalPort.handleInvalid

Imposition time: IT_SysDesc

⌈If the ISignalPort has a networkRepresentationProps.invalidValue defined then the ISignalPort.communicationDirection shall equal in.⌋

[constr_5054] externalReplacement not applicable for ISignalPort.handleInvalid

Imposition time: IT_SysDesc

⌈In the context of ISignalPort.handleInvalid the value externalReplacement shall not be used.⌋

The action externalReplacement can only be implemented by the RTE. Thus it is required to have a ComSpec definition.

[TPS_SYST_02210] Data invalidation in case the dataTypePolicy is set to override or legacy ⌈If the dataTypePolicy of an ISignal is set to override or legacy, the ISignalPort.handleInvalid attribute defines the data invalidation.⌋

6.1.1 Ownership of PduTriggerings

PduTriggerings are owned by PhysicalChannels. A PduTriggering can not exist on its own, it has to be aggregated by exactly one PhysicalChannel (see figure 6.2). In figure 6.4 the example of section 6.11.2.1.2 is taken to illustrate the ownership of PduTriggerings.

If a SecuredIPdu is transmitted on different PhysicalChannels this can be described in a System Description by a single SecuredIPdu element that is referenced by PduTriggerings of the different PhysicalChannels (*PduTriggeringCan* and *PduTriggeringFr*).

The payload of the SecuredIPdu is described by exactly one PduTriggering (*PduTriggeringSec*) that is referenced in the role SecuredIPdu.payload.

Note on the right side that, although the payload PduTriggering (*PduTriggeringSec*) will also be transmitted on the same PhysicalChannels as the SecuredIPdu, it is completely sufficient that the payload PduTriggering (*PduTriggeringSec*) that is referenced by the SecuredIPdu is aggregated by one of the PhysicalChannels on which the SecuredIPdu is transmitted. It is irrelevant which PduTriggering of which PhysicalChannel is chosen to describe the payload of the SecuredIPdu since the assignment of the SecuredIPdu to PhysicalChannels is done only by the PduTriggerings that are pointing to the SecuredIPdu. Thus either the *orange* or the *red* aggregation represent the ownership of the PduTriggering (*PduTriggeringSec*).

This can be motivated by the left part of figure 6.4: The path from RTE, via COM, PduR, SecOC, and back to the PduR has just one flow. The fan-out actually happens only after the message has entered the PduR from the SecOC, only then there are two paths to the target networks.

The reason for this modeling is the configuration of the PduR. One use case in the PduR is the enabling and disabling of PDUs by PdurIPduGroups. The PdurIPduGroup works on PduTriggerings and there is also the use case to enable/disable the SecuredIPdus in the PduR.

A similar example can also be observed in the context of ContainerIPdus as discussed in section 6.11.2.1.3.

[TPS_SYST_03117] Only one PduTriggering for the payload of a ContainerIPdu or SecuredIPdu in case of fan-out ⌈If a PduTriggering is defined as payload of a ContainerIPdu or SecuredIPdu and this ContainerIPdu or SecuredIPdu is fan-out to several PhysicalChannels, then it is sufficient that the payload PduTriggering is aggregated by one of the target PhysicalChannels.

It is irrelevant by which PhysicalChannel the payload PduTriggering is aggregated, as long as one of the transporting PhysicalChannels aggregates the payload PduTriggering.⌋

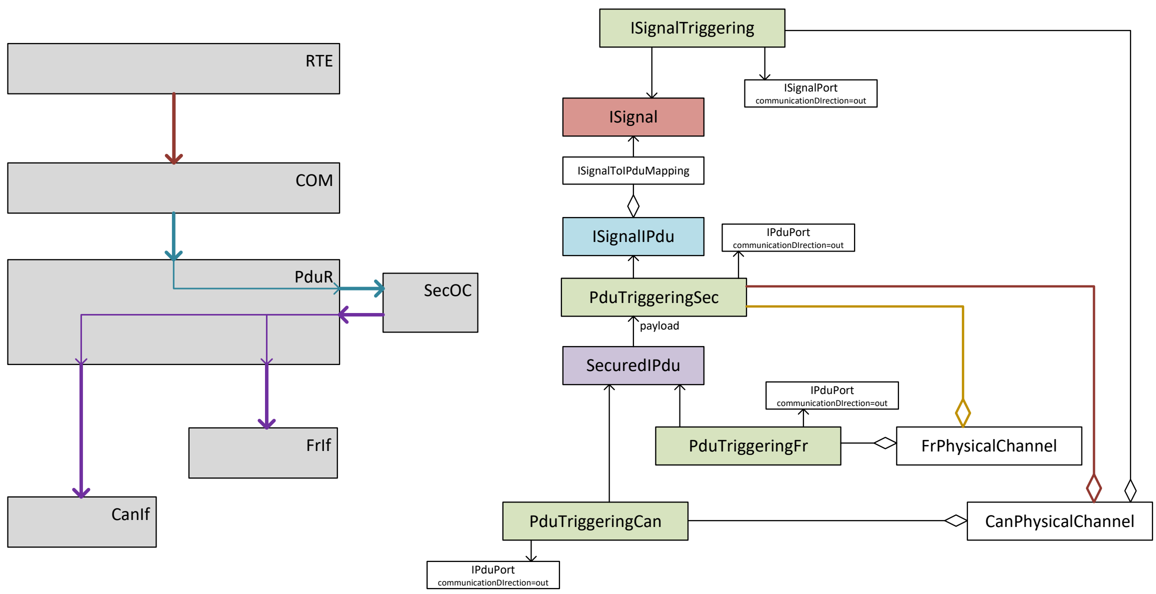

Figure 6.4: Ownership of PduTriggerings in case of fan-out

Although [TPS_SYST_03117] claims that it is irrelevant which PhysicalChannel aggregates the payload PduTriggering, there are scenarios where the surrounding modeling might be influenced by the choice which PhysicalChannel aggregates the payload PduTriggering. The example illustrated in figure 6.120 can be modeled in two ways, this is shown in figure 6.5.

If the *FrPhysicalChannel* aggregates the *PduTriggeringSec*, then it is required to model another PduTriggering which is then aggregated by the *CanPhysicalChannel* (illustrated in orange).

If already the *CanPhysicalChannel* aggregates the *PduTriggeringSec* (illustrated in red), then there is no need to have another PduTriggering, because it is already modeled that *PduTriggeringSec* shall be transported on the *CanPhysicalChannel*.

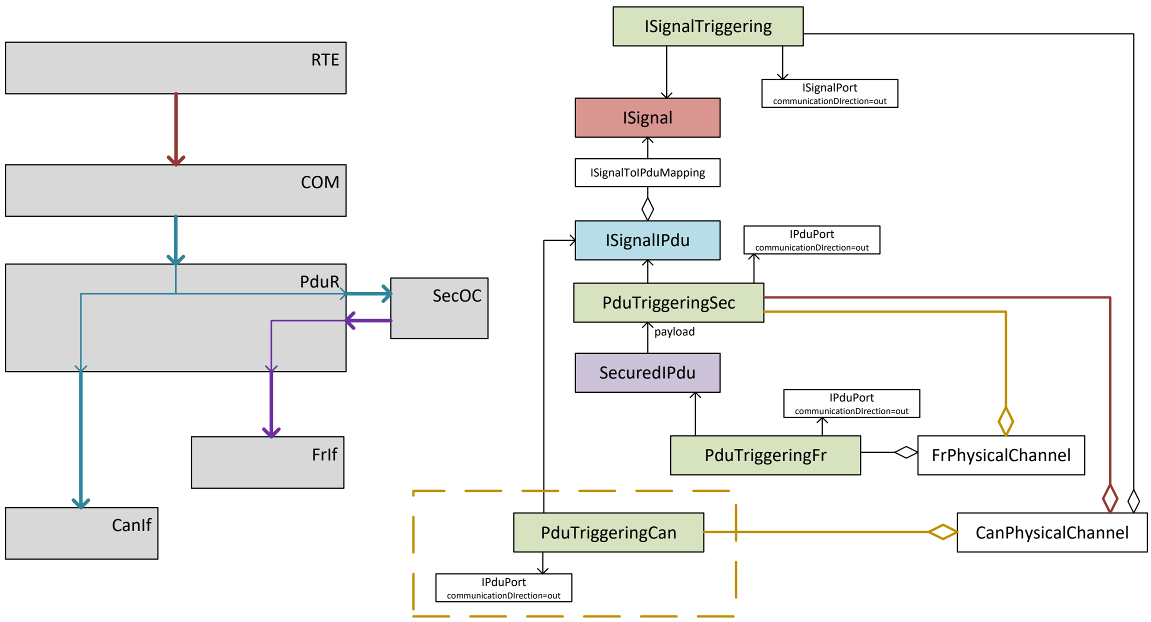

Figure 6.5: Alternative ownership of PduTriggerings in case of fan-out

6.1.2 Ownership of ISignalTriggerings

ISignalTriggerings are owned by PhysicalChannels. An ISignalTriggering can not exist on its own, it has to be aggregated by exactly one PhysicalChannel (see figure 6.2). In figure 6.6 the example of section 6.11.2.1.1 is taken to illustrate the ownership of ISignalTriggerings.

Note on the right side that, although the ISignal will also be transmitted on the same PhysicalChannels as the ISignalIPdu, it is completely sufficient that the ISignalTriggering that is referenced by the ISignalIPdu is aggregated by one of the PhysicalChannels on which the ISignalIPdu is transmitted. It is irrelevant which ISignalTriggering of which PhysicalChannel is chosen to describe the existence of the ISignalTriggering. Thus either the *orange* or the *red* aggregation represent the ownership of the ISignalTriggering.

This can be motivated by the left part of figure 6.6: The path from RTE, via COM, and to the PduR has just one flow. The fan-out actually happens only after the message has entered the PduR, only then there are two paths to the target networks.

[TPS_SYST_03118] Only one ISignalTriggering in case of PDU fan-out ⌈If an ISignalIPdu is defined to be fan-out to several PhysicalChannels, then it is sufficient that the ISignalTriggerings of that ISignalIPdu are aggregated by one of the target PhysicalChannels.

It is irrelevant by which PhysicalChannel the ISignalTriggerings are aggregated, as long as one of the transporting PhysicalChannels aggregates the ISignalTriggerings.⌋

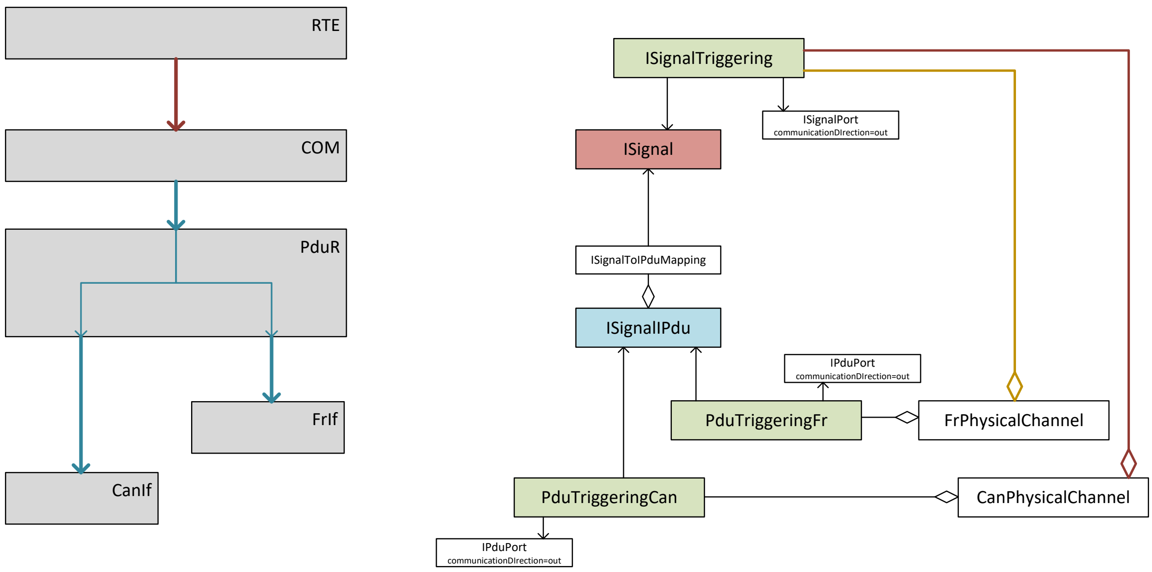

Figure 6.6: Ownership of ISignalTriggerings in case of fan-out

6.2 ISignals

SystemSignals can be defined independently of CommunicationClusters and are representing the VariableDataPrototypes, ArgumentDataPrototypes, Triggers and ModeDeclarationGroupPrototypes in the communication description.

The RTE supports a "signal fan-out" where the same signal (System Signal) is sent in different IPdus to multiple receivers. The Pdu Router supports the "PDU fan-out" where the same IPdu is sent to multiple destinations.

To support the "signal fan-out" ISignals and ISignalGroups are introduced. An ISignal(ISignalGroup) represents the SystemSignal(SystemSignalGroup) of the Interaction Layer.

In case of "signal fan-out", several ISignals in different IPdus refer to the same SystemSignal. The "Signal fan-out" will be executed by the RTE. ISignals describe the Interface between the precompile configured RTE and the potentially postbuild configured Com Stack.

The ISignalToIPduMapping element describes the mapping of ISignals to ISignalIPdus and defines the position of an ISignal within an ISignalIPdu.

[constr_3009] Overlapping of ISignals is prohibited

Imposition time: IT_SysDesc

⌈ISignals mapped to an ISignalIPdu shall not overlap.⌋

[constr_5253] Value range of ISignal.length

Imposition time: IT_SysDesc

⌈The value of ISignal.length shall be in the range of 0..34359738360 Bits.⌋

[constr_3010] ISignalIPdu length shall not be exceeded

Imposition time: IT_SysDesc

⌈The combined length of all ISignals and updateIndicationBitPositions that are mapped into an ISignalIPdu shall not exceed the defined Pdu length.⌋

[constr_3011] Overlapping of updateIndicationBits of ISignals is prohibited

Imposition time: IT_SysDesc

⌈The updateIndicationBitPosition for an ISignal in an ISignalIPdu shall not overlap with other updateIndicationBitPositions or ISignal locations.⌋

[TPS_SYST_01062] Network representation of an ISignal

Upstream requirements: RS_SYST_00047

⌈With the aggregation of SwDataDefProps in the role networkRepresentationProps the actual representation of the ISignal on the network can be specified.⌋

[TPS_SYST_01063] Context of network representation of an ISignal

Upstream requirements: RS_SYST_00001, RS_SYST_00047

⌈The dataTypePolicy defines from which context the network representation specification shall be taken.⌋

For an alternative network representation it is important to define an alternative SwDataDefProps especially SwBaseType defining alternative encoding (e.g. from float in PortInterface to integer on bus).

[constr_3060] Allowed Attributes for networkRepresentationProps and physicalProps

Imposition time: IT_SysDesc

⌈

Attributes of SwDataDefProps	SystemSignal.physicalProps	ISignal.networkProps
additionalNativeTypeQualifier	NA	NA
annotation	NA	NA
baseType	NA	D

⌋

The following settings apply in [constr_3060]:

D Define the attribute independent from settings to the left.

I Inherit the definition from the left for usage in the scope of this element. This means that the information is taken over in the respective context without further ARXML configuration. The attribute of the SwDataDefProps shall not exist on the right side.

NA Attribute is **not applicable** for usage in the scope of this element.

M Attribute is **meaningless** in the scope of this element. As it was allowed in previous versions, declaring it as Not Applicable (NA) would break compatibility. Tools shall ignore such an attribute without a warning.

In case that the System Description doesn't use a complete Software Component Description (VFB View) the physicalProps and networkRepresentationProps are used to configure the Data Semantics.

The networkRepresentationProps contains a reference to the SwBaseType. This reference can be used for the derivation of the ComSignalType in the AUTOSAR Com Configuration.

Please note that a DataTransformation that is based on the network representation is explained in more detail in chapter 7.3.2.2.1. This chapter also contains an explanation that describes a data conversion based on CompuMethods (see section 7.3.2.2.1.1 for more details).

[TPS_SYST_02001] networkRepresentationProps are mandatory in case the dataTypePolicy is set to override or legacy ⌈If the dataTypePolicy of an ISignal is set to override or legacy, the networkRepresentationProps for the respective ISignal have to be specified.⌋

[TPS_SYST_02006] Usage of networkRepresentationFromComSpec ⌈If the networkRepresentationFromComSpec is used either the SwDataDefProps in the role networkRepresentation aggregated by the SenderComSpec or ReceiverComSpec shall exist or the ImplementationDataType shall exist.⌋

Please note that some categorys of CompuMethod cannot be successfully converted to A2L [20] because A2L does not provide an equivalent semantics that comes close to the respective AUTOSAR semantics.

A prominent example for such a case is a CompuMethod of category SCALE_LINEAR_AND_TEXTTABLE that actually has more than one linear interval and a texttable part.

[TPS_SYST_02079] Identification of ImplementationDataType for a given ISignal in an Ecu Extract ⌈

1. From the ISignal go to the referenced SystemSignal
2. Find all DataMappings that refer to the SystemSignal
3. For all VariableDataPrototypes referenced by the applicable DataMappings

(a) If the VariableDataPrototype is typed by an ApplicationDataType and belongs to a CompositionSwComponentType then for all DataTypeMappingSets referenced by the CompositionSwComponentType find the DataTypeMap that refers to this ApplicationDataType. The DataTypeMap also refers to the wanted ImplementationDataType.

(b) If the VariableDataPrototype is typed by an ApplicationDataType and belongs to an AtomicSwComponentType then for all DataTypeMappingSets referenced by the InternalBehavior of the AtomicSwComponentType find the DataTypeMap that refers to this ApplicationDataType. The DataTypeMap also refers to the wanted ImplementationDataType.

(c) If the VariableDataPrototype is typed by an ImplementationDataType then the ImplementationDataType is the wanted one.

⌋

[TPS_SYST_02076] networkRepresentationProps in case the dataTypePolicy is set to transformingISignal ⌈If the value of ISignal.dataTypePolicy is set to transformingISignal then ISignal.networkRepresentationProps shall be ignored.⌋

[constr_3199] ISignal that has dataTypePolicy set to transformingISignal shall reference a DataTransformation

Imposition time: IT_SysDesc

⌈In a complete model every ISignal that has dataTypePolicy set to transformingISignal shall reference a DataTransformation.⌋

[constr_3736] ISignal that has dataTypePolicy set to ddsSignal shall be referenced by a DdsCpISignalToDdsTopicMapping

Imposition time: IT_SysDesc

⌈Every ISignal that has dataTypePolicy set to ddsSignal shall be referenced by a DdsCpISignalToDdsTopicMapping.⌋

[constr_3737] ISignal referenced from DdsCpISignalToDdsTopicMapping

Imposition time: IT_SysDesc

⌈Every ISignal that has dataTypePolicy set to any value different to ddsSignal shall NOT be referenced by a DdsCpISignalToDdsTopicMapping.⌋

DDS Data is created in the application layer and passed to DDS directly (as unserialised data): any modification nor transformation (and vice versa at receiver side) should be performed on data. Serialization is performed inside the Dds BSW and it is completely opaque to the AUTOSAR stack.

Note: no transformation nor serialization should be performed even for composite data type: the data would be copied to the ISignal (in the LdCom buffer) and will arrive completely unmodified in the DDS module.

[constr_3738] ISignal that has dataTypePolicy set to ddsSignal or to ddsService shall not reference a DataTransformation

Imposition time: IT_SysDesc

⌈In a complete model every ISignal that has dataTypePolicy set to ddsSignal or to ddsService shall NOT reference to any DataTransformation.⌋

[TPS_SYST_01065] Mapping onto the ComSignalType enumeration

Upstream requirements: RS_SYST_00029

⌈

BOOLEAN	ignored	primitive	not applicable	BOOLEAN

The table describes the mapping of baseTypeSize, baseTypeEncoding, ISignal.iSignalType and SystemSignal.dynamicLength onto the ComSignalType enumeration

⌋

In other words [TPS_SYST_01065] focuses only on the derivation of the ComSignal-Type. This table shall not be taken as a source to derive requirements on the modeling of SwBaseTypes used on the level of the RTE.

The setting "not applicable" for an Attribute in [TPS_SYST_01065] means that no value shall be set for this Attribute. The setting "ignored" for an Attribute in [TPS_SYST_01065] means than any value is accepted for this Attribute, but the value will be ignored in creation of the ECU configuration value file.

[constr_3258] Restriction on ISignal.length in case iSignalType is set to array

Imposition time: IT_SysDesc

⌈If ISignal.iSignalType is set to array then ISignal.length shall be a multiple of 8.⌋

[TPS_SYST_02111] VariableDataPrototype in case ISignal.iSignalType is set to array ⌈If ISignal.iSignalType is set to array the corresponding VariableDataPrototype shall boil down to an Array according to [TPS_SYST_02083], [TPS_SYST_02084], [TPS_SYST_02085] and [TPS_SYST_02089].⌋

The invalidValue is aggregated by the SwDataDefProps element. The SwDataDefProps and the SwBaseType classes are described in more detail in the Software Component Template [4].

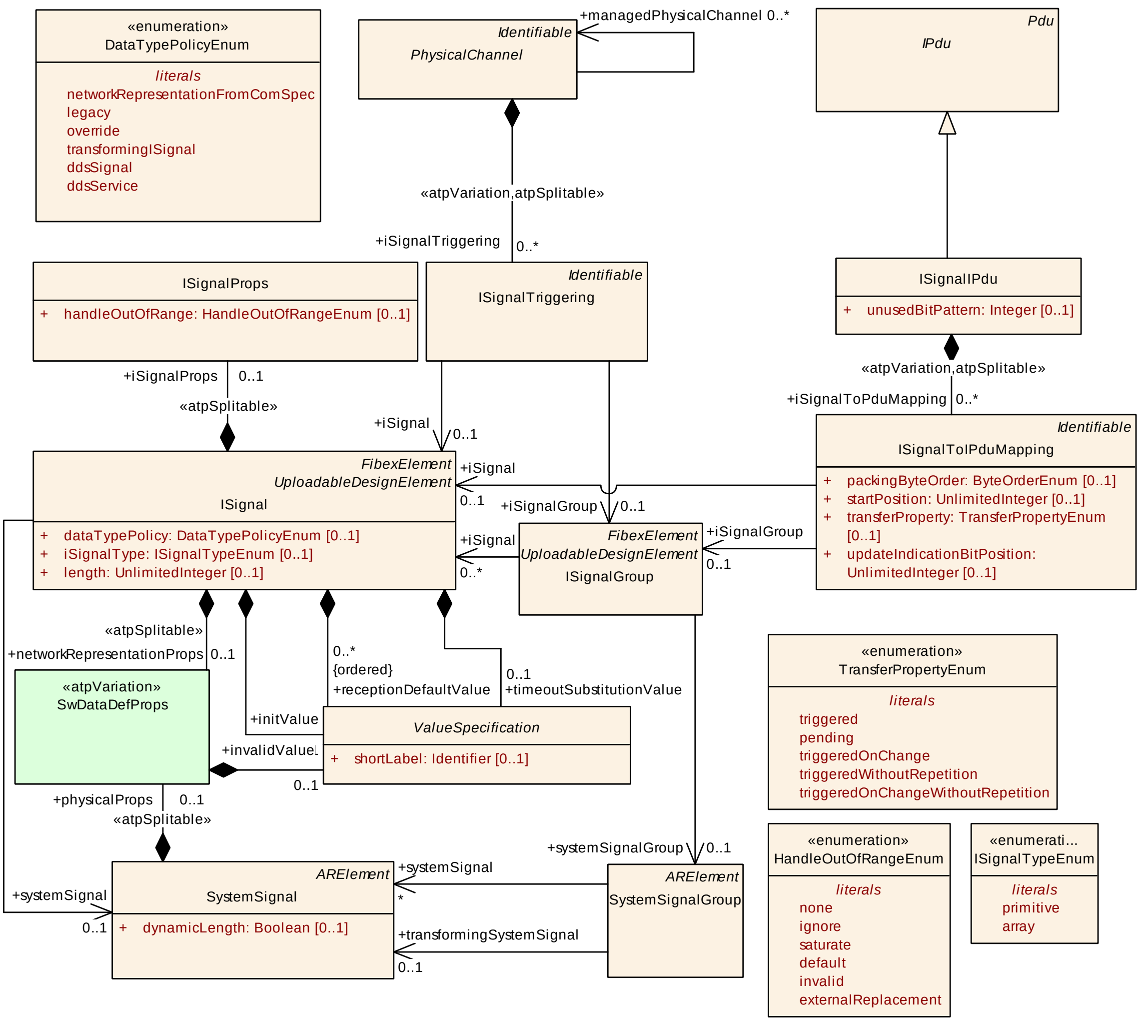

Figure 6.7: ISignals and the mapping into IPdus (FibexCore: SignalOverview)

The configuration of the COM Module for atomic signals can largely be derived from the System Template.

[TPS_SYST_01066] Derivation of Tx COM Signals ⌈A ComSignal shall be defined in the COM module configuration for each ISignalToIPduMapping that is aggregated by ISignalIPdu that in turn is referenced by a PduTriggering that in turn references an IPduPort where the communicationDirection is set to out of the regarded ECU.

Exception: If the ISignal is part of a Signal Gateway relation (ISignalMapping.targetSignal pointing to an ISignalTriggering referencing this ISignal) the creation of a ComSignal is not mandated if

- the ISignal does not point to a SystemSignal that is referenced by a DataMapping (application does not send the gatewayed signal content) or
- the ISignal points to a SystemSignal that is referenced by a DataMapping in which the RPortPrototype is used as the context element and

the destination ISignalTriggering.iSignalPort.communicationDirection equals out (application sends the gatewayed signal content) or

- the ISignalToIPduMapping.iSignal.dataTypePolicy is set to legacy.

In these cases the configuration of ComGwMapping can be done by means of ComGwSourceDescription and ComGwDestinationDescription. However it is possible to create ComSignals for the ComGwSignal approach as well (i.e., even if the application does not require access to the respective SystemSignal).⌋

[TPS_SYST_01067] Derivation of Rx COM Signals ⌈A ComSignal shall be defined in the COM module configuration for each ISignalToIPduMapping that is aggregated by ISignalIPdu that in turn is referenced by a PduTriggering that in turn references an IPduPort where the communicationDirection is set to in in the regarded ECU.

Exception: If the ISignal is part of a Signal Gateway relation (ISignalMapping.sourceSignal pointing to an ISignalTriggering referencing this ISignal) the creation of a ComSignal is not mandated if

- the ISignal does not point to a SystemSignal that is referenced by a DataMapping (application is not interested in the gatewayed signal content) or
- the ISignal points to a SystemSignal that is referenced by a DataMapping in which the PPortPrototype is used as the context element and source ISignalTriggering.iSignalPort.communicationDirection equals in (application is not interested in the gatewayed signal content) or
- the ISignalToIPduMapping.iSignal.dataTypePolicy is set to legacy.

In these cases the configuration of ComGwMapping can be done by means of ComGwSourceDescription and ComGwDestinationDescription. However it is possible to create ComSignals for the ComGwSignal approach as well (i.e., even if the application does not require access to the respective SystemSignal).⌋

To support the AUTOSAR concept of composite data types the AUTOSAR COM layer provides signal groups. Every record or array element of a composite data type requires a SystemSignal for the transmission. But the RTE has to guarantee the consistent transmission of data.

[TPS_SYST_01153] Atomic transport of SystemSignalGroups ⌈A SystemSignalGroup shall be transmitted and received consistently; therefore it provides data consistency for composite data types.⌋

A SystemSignalGroup refers to a set of SystemSignals that shall always be kept together in a common IPdu. An ISignalGroup represents a SystemSignalGroup of the Interaction Layer. In the case of "signal fan-out", several ISignalGroups refer to the same SystemSignalGroup.

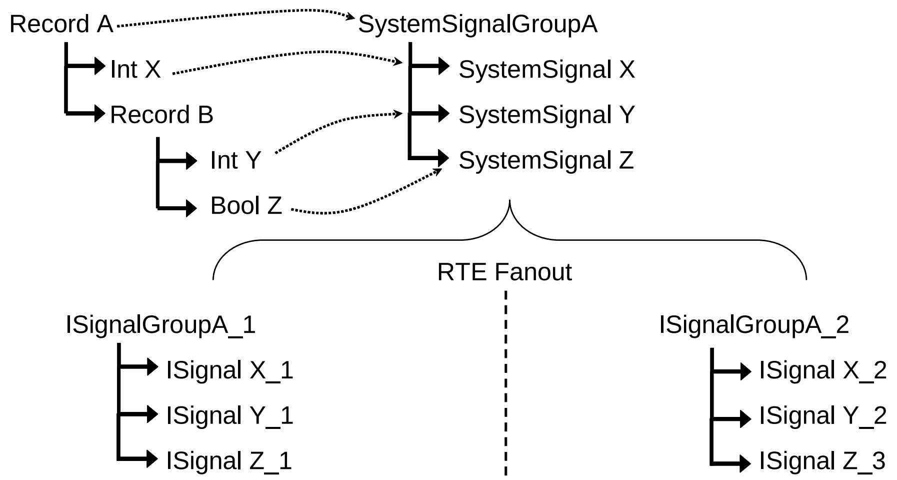

Figure 6.8: ISignal example

The example in Figure 6.8 shows the usage of ISignalGroups and ISignals. In this example a record is mapped to a SystemSignalGroup. All ApplicationRecordElements with ApplicationPrimitiveDataType are mapped to individual SystemSignals. If the same SystemSignalGroup is sent to different receivers (RTE Fanout) then two different ISignalGroups are created. For each SystemSignal within the SystemSignalGroup an ISignal is created. The different ISignals of the same SystemSignal can have different network representations.

[constr_3094] Consistent ISignalPort.communicationDirection for ISignalTriggerings of ISignalGroups and contained ISignals

Imposition time: IT_SysDesc

⌈In case the ISignals contained in an ISignalGroup are referenced by an ISignalTriggering, the communicationDirection of the ISignalPort referenced by the ISignal's ISignalTriggering shall be identical to the communicationDirection of the ISignalPort referenced by the containing ISignalGroup's ISignalTriggering.⌋

Please note that not all ISignals that are part of the ISignalGroup need to have a reference to an ISignalPort via an ISignalTriggering as described by [TPS_SYST_02106].

[TPS_SYST_01157] Allowed usage of attributes for ISignals, ISignalGroups and GroupSignals ⌈

Attributes	ISignal	ISignalGroup	GroupSignal
startPosition	1	NA	1
updateIndicationBitPosition	0..1	0..1	NA
transferProperty	0..1	0..1	0..1

▽

△

packingByteOrder	1	NA	1
dataFilter	0..1	NA	0..1

Attributes that may be used to configure ISignals in different roles (ISignals that are not part of an ISignalGroup and ISignals that are part of an ISignalGroup) and ISignalGroups.

⌋

[constr_3067] initValue defined in the context of ISignal

Imposition time: IT_SysDesc

⌈The definition of an initValue in the context of an ISignal shall only be a NumericalValueSpecification, TextValueSpecification or ArrayValueSpecification that aggregates elements of type NumericalValueSpecification or TextValueSpecification.⌋

Please note that for ISignals that are referencing a SystemSignal with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE the [constr_3067] is further restricted by [advisory_03000] for the definition of the initValue. [advisory_03000] corresponds to the [constr_1225] that is defined in the Software Component Template [4].

[advisory_03000] initValue defined in the context of ISignal that references a SystemSignal with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE

Imposition time: IT_SysDesc

⌈If an ISignal references a SystemSignal that in turn aggregates physicalProps with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE then the definition of an initValue of the ISignal should be a TextValueSpecification. In this case the value provided should match to the applicable text values (vt, shortLabel,symbol, where the preference rule defined in [TPS_SWCT_01696] is applied) defined by the applicable CompuScales.⌋

[constr_3437] invalidValue defined in the context of ISignal

Imposition time: IT_SysDesc

⌈The definition of SwDataDefProps.invalidValue aggregated by an ISignal in the role networkRepresentationProps shall only be a NumericalValueSpecification, TextValueSpecification or ArrayValueSpecification that aggregates elements of type NumericalValueSpecification or TextValueSpecification.⌋

Please note that for ISignals that are referencing a SystemSignal with a CompuMethod of category category TEXTTABLE or BITFIELD_TEXTTABLE the [constr_3067] is further restricted by [advisory_03001] for the definition of the invalidValue. [advisory_03001] corresponds to the [constr_10196] that is defined in the Software Component Template [4].

[advisory_03001] invalidValue defined in the context of ISignal that references a SystemSignal with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE

Imposition time: IT_SysDesc

⌈If an ISignal references a SystemSignal that in turn aggregates physicalProps with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE then the definition of an invalidValue of the ISignal should be a TextValueSpecification if the value fits into the intervals defined by the CompuMethod. In this case the value provided should match to one of the applicable text values (vt, shortLabel, symbol, where the preference rule defined in [TPS_SWCT_01696] is applied) defined by the applicable CompuScales.⌋

[constr_3438] timeoutSubstitutionValue defined in the context of ISignal

Imposition time: IT_SysDesc

⌈The definition of an timeoutSubstitutionValue in the context of an ISignal shall only be a NumericalValueSpecification, TextValueSpecification or ArrayValueSpecification that aggregates elements of type NumericalValueSpecification or TextValueSpecification.⌋

Please note that for ISignals that are referencing a SystemSignal with a CompuMethod of category category TEXTTABLE or BITFIELD_TEXTTABLE the [constr_3438] is further restricted by [advisory_03002] for the definition of the timeoutSubstitutionValue. [advisory_03002] corresponds to the [constr_1225] that is defined in the Software Component Template [4].

[advisory_03002] timeoutSubstitutionValue defined in the context of ISignal that references a SystemSignal with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE

Imposition time: IT_SysDesc

⌈If an ISignal references a SystemSignal that in turn aggregates physicalProps with a CompuMethod of category TEXTTABLE or BITFIELD_TEXTTABLE then the definition of an timeoutSubstitutionValue of the ISignal should be a TextValueSpecification. In this case the value provided should match to one of the applicable text values (vt, shortLabel,symbol, where the preference rule defined in [TPS_SWCT_01696] is applied) defined by the applicable CompuScales.⌋

[TPS_SYST_02012] initValue and invalidValue represent internal values ⌈The initValue and invalidValue aggregated by the networkRepresentationProps shall represent the internal values.⌋

[TPS_SYST_02110] Default behavior for ISignal.iSignalType ⌈In case ISignal.iSignalType is not defined the value "primitive" shall be assumed.⌋

[TPS_SYST_02144] ComTimeoutSubstitution does not apply for signal gateway operation ⌈The specification of ComTimeoutSubstitution by defining the ISignal.timeoutSubstitutionValue does not apply for signal gateway operation. Only when the ISignal is processed for an upper layer the ComTimeoutSubstitution is actually performed.⌋

Note: Since an ISignal may be candidate for both - local reception and gateway operation - a definition of ISignal.timeoutSubstitutionValue is valid on ISignals which are defined for gateway operation.

[TPS_SYST_03122] ISignal.receptionDefaultValue configured for SOME/IP Serializer "less data than expected received" ⌈The ISignal.receptionDefaultValue (if defined) shall be used for the configuration of the SOME/IP Serializer "less data than expected received" (see [SWS_SomeIpXf_00017]) if:

the ISignal references a DataTransformation in the role ISignal.dataTransformation and that DataTransformation refers to a TransformationTechnology in the role DataTransformation.transformerChain that has the attribute TransformationTechnology.protocol set to the value "SOMEIP".⌋

[constr_3779] Number of ISignal.receptionDefaultValue elements

Imposition time: IT_SysDesc

⌈At most one entry of ISignal.receptionDefaultValue shall be defined at each ISignal. The definition of ISignal.receptionDefaultValue shall adhere to [constr_3780].⌋

The background for defining ISignal.receptionDefaultValue as an ordered collection is the potential future extension of this approach to client/server communication.

Further details on the usage of ISignal.receptionDefaultValue in the scope of [constr_3779] are described in section 7.3.2.3

Class	**ISignal**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	Signal of the Interaction Layer. The RTE supports a "signal fan-out" where the same System Signal is sent in different SignalIPdus to multiple receivers. To support the RTE "signal fan-out" each SignalIPdu contains ISignals. If the same System Signal is to be mapped into several SignalIPdus there is one ISignal needed for each ISignalToIPduMapping. ISignals describe the Interface between the Precompile configured RTE and the potentially Postbuild configured Com Stack (see ECUC Parameter Mapping). In case of the SystemSignalGroup an ISignal shall be created for each SystemSignal contained in the SystemSignalGroup. **Tags:** atp.recommendedPackage=ISignals			
Base	*ARElement*, *ARObject*, *CollectableElement*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
data Transformation	DataTransformation	0..1	ref	Optional reference to a DataTransformation which represents the transformer chain that is used to transform the data that shall be placed inside this ISignal. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=dataTransformation.dataTransformation, dataTransformation.variationPoint.shortLabel vh.latestBindingTime=codeGenerationTime
dataTypePolicy	DataTypePolicyEnum	0..1	attr	With the aggregation of SwDataDefProps an ISignal specifies how it is represented on the network. This representation follows a particular policy. Note that this causes some redundancy which is intended and can be used to support flexible development methodology as well as subsequent integrity checks. If the policy "networkRepresentationFromComSpec" is chosen the network representation from the ComSpec that is aggregated by the PortPrototype shall be used. If the "override" policy is chosen the requirements specified in the PortInterface and in the ComSpec are not fulfilled by the networkRepresentationProps. In case the System Description doesn't use a complete Software Component Description (VFB View) the "legacy" policy can be chosen.
initValue	ValueSpecification	0..1	aggr	Optional definition of a ISignal's initValue in case the System Description doesn't use a complete Software Component Description (VFB View). This supports the inclusion of legacy system signals. This value can be used to configure the Signal's "Init Value". If a full DataMapping exist for the SystemSignal this information may be available from a configured Sender ComSpec and ReceiverComSpec. In this case the initvalues in SenderComSpec and/or ReceiverComSpec override this optional value specification. Further restrictions apply from the RTE specification.
iSignalProps	ISignalProps	0..1	aggr	Additional optional ISignal properties that may be stored in different files. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=iSignalProps
iSignalType	ISignalTypeEnum	0..1	attr	This attribute defines whether this iSignal is an array that results in a UINT8_N / UINT8_DYN ComSignalType in the COM configuration or a primitive type.

▽

△

Class	ISignal			
length	UnlimitedInteger	0..1	attr	Size of the signal in bits. The size needs to be derived from the mapped VariableDataPrototype according to the mapping of primitive DataTypes to BaseTypes as used in the RTE. Indicates maximum size for dynamic length signals. The ISignal length of zero bits is allowed.
network Representation Props	SwDataDefProps	0..1	aggr	Specification of the actual network representation. The usage of SwDataDefProps for this purpose is restricted to the attributes compuMethod and baseType. The optional baseType attributes "memAllignment" and "byteOrder" shall not be used. The attribute "dataTypePolicy" in the SystemTemplate element defines whether this network representation shall be ignored and the information shall be taken over from the network representation of the ComSpec. If "override" is chosen by the system integrator the network representation can violate against the requirements defined in the PortInterface and in the network representation of the ComSpec. In case that the System Description doesn't use a complete Software Component Description (VFB View) this element is used to configure "ComSignalDataInvalid Value" and the Data Semantics. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=networkRepresentationProps
reception DefaultValue (ordered)	ValueSpecification	*	aggr	Value used to fill data on the receiver side, if less then expected data is received. The value is expected to cover the entire expected ISignal network payload.
systemSignal	SystemSignal	0..1	ref	Reference to the System Signal that is supposed to be transmitted in the ISignal.
timeout Substitution Value	ValueSpecification	0..1	aggr	Defines and enables the ComTimeoutSubstituition for this ISignal.
transformation ISignalProps	TransformationISignal Props	*	aggr	A transformer chain consists of an ordered list of transformers. The ISignal specific configuration properties for each transformer are defined in the TransformationISignalProps class. The transformer configuration properties that are common for all ISignals are described in the TransformationTechnology class. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=transformationISignalProps

Table 6.7: ISignal

[constr_9222] Existence of `ISignal.dataTypePolicy`

Imposition time: `IT_SysDesc`

⌈For each `ISignal`, the attribute `dataTypePolicy` shall exist.⌋

[constr_9223] Existence of `ISignal.length`

Imposition time: `IT_SysDesc`

△

Class	**ISignalGroup**			
comBased SignalGroup Transformation	DataTransformation	0..1	ref	Optional reference to a DataTransformation which represents the transformer chain that is used to transform the data that shall be placed inside this ISignalGroup based on the COMBasedTransformer approach. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=comBasedSignalGroupTransformation.data Transformation, comBasedSignalGroup Transformation.variationPoint.shortLabel vh.latestBindingTime=codeGenerationTime
iSignal	ISignal	*	ref	Reference to a set of ISignals that shall always be kept together.
systemSignal Group	SystemSignalGroup	0..1	ref	Reference to the SystemSignalGroup that is defined on VFB level and that is supposed to be transmitted in the ISignalGroup.
transformation ISignalProps	TransformationISignal Props	*	aggr	A transformer chain consists of an ordered list of transformers. The ISignalGroup specific configuration properties for each transformer are defined in the TransformationISignalProps class. The transformer configuration properties that are common for all ISignal Groups are described in the TransformationTechnology class. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=transformationISignalProps

Table 6.12: ISignalGroup

[constr_9225] Existence of ISignalGroup.systemSignalGroup

Imposition time: IT_SysDesc

⌈For each ISignalGroup, the reference to SystemSignalGroup in the role systemSignalGroup shall exist.⌋

Class	**SystemSignalGroup**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	A signal group refers to a set of signals that shall always be kept together. A signal group is used to guarantee the atomic transfer of AUTOSAR composite data types. The SystemSignalGroup defines a signal grouping on VFB level. On cluster level the Signal grouping is described by the ISignalGroup element. **Tags:** atp.recommendedPackage=SystemSignalGroups			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
systemSignal	SystemSignal	*	ref	Reference to a set of SystemSignals that shall always be kept together.
transforming SystemSignal	SystemSignal	0..1	ref	Optional reference to the SystemSignal which shall contain the transformed (linear) data.

Table 6.13: SystemSignalGroup

Class	ISignalToIPduMapping			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	An ISignalToIPduMapping describes the mapping of ISignals to ISignalIPdus and defines the position of the ISignal within an ISignalIPdu.			
Base	*ARObject, Identifiable, MultilanguageReferrable, Referrable*			
Aggregated by	ISignalIPdu.iSignalToPduMapping, NmPdu.iSignalToIPduMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
iSignal	ISignal	0..1	ref	Reference to a ISignal that is mapped into the ISignal IPdu. Each ISignal contained in the ISignalGroup shall be mapped into an IPdu by an own ISignalToIPduMapping. The references to the ISignal and to the ISignalGroup in an ISignalToIPduMapping are mutually exclusive.
iSignalGroup	ISignalGroup	0..1	ref	Reference to an ISignalGroup that is mapped into the SignalIPdu. If an ISignalToIPduMapping for an ISignal Group is defined, only the UpdateIndicationBitPosition and the transferProperty is relevant. The startPosition and the packingByteOrder shall be ignored. Each ISignal contained in the ISignalGroup shall be mapped into an IPdu by an own ISignalToIPduMapping. The references to the ISignal and to the ISignalGroup in an ISignalToIPduMapping are mutually exclusive.
packingByte Order	ByteOrderEnum	0..1	attr	This parameter defines the order of the bytes of the signal and the packing into the SignalIPdu. The byte ordering "Little Endian" (MostSignificantByteLast), "Big Endian" (MostSignificantByteFirst) and "Opaque" can be selected. For opaque data endianness conversion shall be configured to Opaque. The value of this attribute impacts the absolute position of the signal into the SignalIPdu (see the startPosition attribute description). For an ISignalGroup the packingByteOrder is irrelevant and shall be ignored.
startPosition	UnlimitedInteger	0..1	attr	This parameter is necessary to describe the bitposition of a signal within an SignalIPdu. It denotes the least significant bit for "Little Endian" and the most significant bit for "Big Endian" packed signals within the IPdu (see the description of the packingByteOrder attribute). In AUTOSAR the bit counting is always set to "sawtooth" and the bit order is set to "Decreasing". The bit counting in byte 0 starts with bit 0 (least significant bit). The most significant bit in byte 0 is bit 7. Please note that the way the bytes will be actually sent on the bus does not impact this representation: they will always be seen by the software as a byte array. If a mapping for the ISignalGroup is defined, this attribute is irrelevant and shall be ignored.
transferProperty	TransferPropertyEnum	0..1	attr	Defines how the referenced ISignal contributes to the send triggering of the ISignalIPdu.

▽

△

Class	ISignalToIPduMapping			
update IndicationBit Position	UnlimitedInteger	0..1	attr	The UpdateIndicationBit indicates to the receivers that the signal (or the signal group) was updated by the sender. Length is always one bit. The UpdateIndicationBitPosition attribute describes the position of the update bit within the SignalIPdu. For Signals of a ISignalGroup this attribute is irrelevant and shall be ignored. Note that the exact bit position of the updateIndicationBit Position is linked to the value of the attribute packingByte Order because the method of finding the bit position is different for the values mostSignificantByteFirst and most SignificantByteLast. This means that if the value of packingByteOrder is changed while the value of update IndicationBitPosition remains unchanged the exact bit position of updateIndicationBitPosition within the enclosing ISignalIPdu still undergoes a change. This attribute denotes the least significant bit for "Little Endian" and the most significant bit for "Big Endian" packed signals within the IPdu (see the description of the packingByteOrder attribute). In AUTOSAR the bit counting is always set to "sawtooth" and the bit order is set to "Decreasing". The bit counting in byte 0 starts with bit 0 (least significant bit). The most significant bit in byte 0 is bit 7.

Table 6.14: ISignalToIPduMapping

[constr_5322] Value range of ISignalToIPduMapping.startPosition

Imposition time: IT_SysDesc

⌈The value of ISignalToIPduMapping.startPosition shall be in the range of 0..4294967295 Bits.⌋

Please note that the range of ISignalToIPduMapping.startPosition is resctricted by [constr_5322] to the max value of 4294967295 Bits because of the defined range of the ComBitPosition parameter that is defined in the COM Configuration [21].

[constr_5323] Value range of ISignalToIPduMapping.updateIndicationBitPosition

Imposition time: IT_SysDesc

⌈The value of ISignalToIPduMapping.updateIndicationBitPosition shall be in the range of 0..4294967295 Bits.⌋

Please note that the range of ISignalToIPduMapping.updateIndicationBitPosition is resctricted by [constr_5323] to the max value of 4294967295 Bits because of the defined range of the ComUpdateBitPosition parameter that is defined in the COM Configuration [21].

[constr_3514] No two ISignalToIPduMappings shall reference the identical ISignal

Imposition time: IT_SysDesc

⌈No two ISignalToIPduMappings shall reference the identical ISignal in the role iSignal in the scope of one System.⌋

Enumeration	TransferPropertyEnum
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication
Note	Transfer Properties of a Signal.
Aggregated by	ISignalToIPduMapping.transferProperty
Literal	**Description**
pending	If the signal has the TransferProperty pending, then the function Com_SendSignal shall not perform a transmission of the IPdu associated with the signal. **Tags:** atp.EnumerationLiteralIndex=0
triggered	The signal in the assigned IPdu is updated and a request for the IPdu's transmission is made. **Tags:** atp.EnumerationLiteralIndex=1
triggeredOnChange	The signal in the assigned IPdu is updated and a request for the IPdus transmission is made only if the signal value is different from the already stored signal value. **Tags:** atp.EnumerationLiteralIndex=2
triggeredOnChange WithoutRepetition	The signal in the assigned IPdu is updated and a request for the IPdus transmission is made only if the signal value is different from the already stored signal value. In the DIRECT/N-TIMES or MIXED transmission mode (EventControlledTiming) the IPdu will be transmitted just once without a repetition, independent of the defined NumberOfRepeats. **Tags:** atp.EnumerationLiteralIndex=3
triggeredWithout Repetition	The signal in the assigned IPdu is updated and a request for the IPdu's transmission is made. In the DIRECT/N-TIMES or MIXED transmission mode (EventControlledTiming) the IPdu will be transmitted just once without a repetition, independent of the defined NumberOfRepeats. **Tags:** atp.EnumerationLiteralIndex=4

Table 6.15: TransferPropertyEnum

[TPS_SYST_02198] Applicable transferProperty for ISignal ⌈If the ISignalToIPduMapping refers to an ISignal in the role iSignal then

- the pending transferProperty does not cause transmission of the ISignalIPdu if the ISignal is updated.
- if the ISignalIPdu has an EventControlledTiming aggregated at the TransmissionModeTiming then the transferProperty values
  - triggered and triggeredWithoutRepetition do cause immediate transmission of the ISignalIPdu if the ISignal is updated.
  - triggeredOnChange and triggeredOnChangeWithoutRepetition do cause immediate transmission of the ISignalIPdu if the ISignal is updated and has changed.

⌈Each `ISignalTriggering` shall either define an `ISignalTriggering.iSignal` or an `ISignalTriggering.iSignalGroup` reference.⌋

6.2.1 Efficient COM for large data

AUTOSAR defines an alternative communication path between the RTE and the Communication Stack called Efficient COM for large data module (LdCom). The System Template does not define specific attributes which would distinguish whether the traditional Com or the LdCom shall be used. The idea behind this feature is rather that

- IF the LdCom module is integrated in an Ecu
- AND the specific interaction fulfills certain properties
- THEN LdCom shall be used.

Thus the usage of LdCom inside an ECU is project specific and is not derived from system description properties.

Note: even when all requirements for usage of LdCom are fulfilled it is not necessarily required to actually have an LdCom module inside the respective Ecu. It is rather a project specific decision whether LdCom module is integrated.

All of the following requirements need to be fulfilled in order to allow the usage of LdCom for the specific `ISignal` / `ISignalIPdu` combination.

[TPS_SYST_02015] LdCom: only one `ISignal` mapped to the `ISignalIPdu`

Upstream requirements: RS_SYST_00049

⌈Only if exactly one `ISignal` is mapped into an `ISignalIPdu` and the LdCom module is present, this `ISignal` shall be handled by LdCom.⌋

[TPS_SYST_02016] LdCom: only Transformer output and UINT8_N or UINT8_DYN supported

Upstream requirements: RS_SYST_00049

⌈Only if

- the data type of the ISignal is either UINT8_N or UINT8_DYN
- or the ISignal has a reference to the DataTransformation in the role dataTransformation

and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02017] LdCom: Opaque ISignalToIPduMapping.packingByteOrder

Upstream requirements: RS_SYST_00049

⌈Only if packingByteOrder has the value "Opaque" and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02018] LdCom: ISignalToIPduMapping.startPosition shall be 0

Upstream requirements: RS_SYST_00049

⌈Only if ISignalToIPduMapping.startPosition equals 0 (zero) and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02019] LdCom: ISignalToIPduMapping.transferProperty shall be triggered or triggeredWithoutRepetition for sent ISignals

Upstream requirements: RS_SYST_00049

⌈Only if ISignalToIPduMapping.transferProperty equals triggered or triggeredWithoutRepetition for a Signal that is sent by the EcuInstance and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02020] LdCom: No IPduTiming.minimumDelay defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. Only if this ISignalIPdu does not contain an IPduTiming in iPduTimingSpecification which has IPduTiming.minimumDelay defined, the ISignalIPdu is sent by the EcuInstance and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02021] LdCom: ISignalToIPduMapping.updateIndicationBitPosition shall not be defined

Upstream requirements: RS_SYST_00049

⌈Only if ISignalToIPduMapping.updateIndicationBitPosition is not defined and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02022] LdCom: Only the transmissionModeTrueTiming defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. Only if this ISignalIPdu has exactly the TransmissionModeDeclaration.transmissionModeTrueTiming defined (via ISignalIPdu.iPduTimingSpecification), the ISignalIPdu is sent by the EcuInstance and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02023] LdCom: DataFilter "always" if TransmissionModeCondition defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. If this ISignalIPdu has either

- no TransmissionModeDeclaration.transmissionModeCondition defined (via ISignalIPdu.iPduTimingSpecification) or
- DataFilter.dataFilterType is set to "always" for the TransmissionModeCondition of this ISignalIPdu.

and this ISignalIPdu is sent by the EcuInstance and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02024] LdCom: No ModeDrivenTransmissionModeCondition defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. Only if this ISignalIPdu has no TransmissionModeDeclaration.modeDrivenTrueCondition and modeDrivenFalseCondition, the ISignalIPdu is sent by the EcuInstance and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02025] LdCom: Only EventControlledTiming defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. Only if this ISignalIPdu has an EventControlledTiming (via TransmissionModeTiming.eventControlledTiming) and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02026] LdCom: Only EventControlledTiming with no repetition defined

Upstream requirements: RS_SYST_00049

⌈The ISignal is mapped into an ISignalIPdu. Only if this ISignalIPdu has an EventControlledTiming (via TransmissionModeTiming.eventControlledTiming) with EventControlledTiming.numberOfRepetitions = 0 defined and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

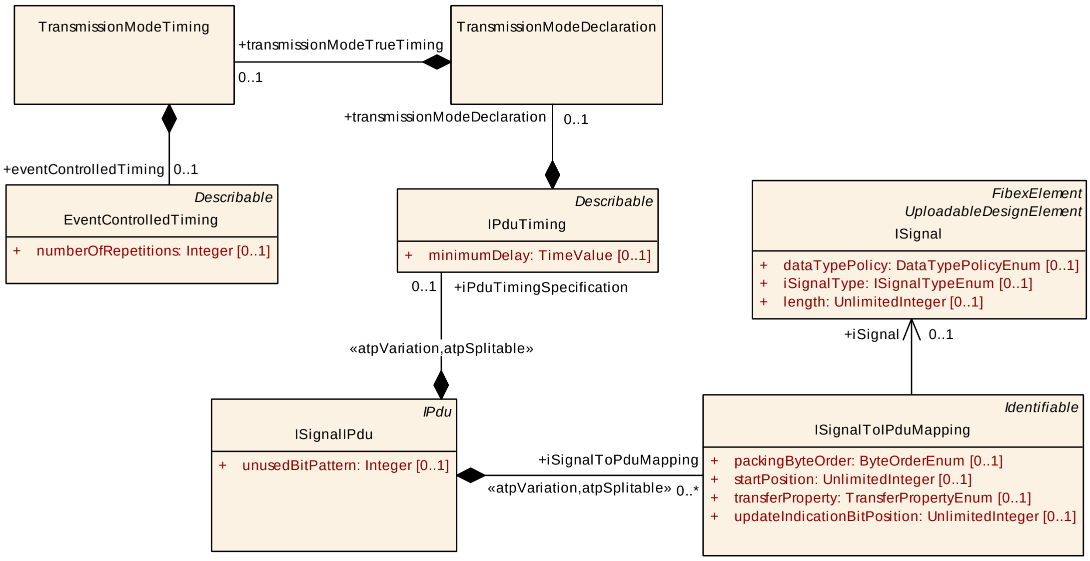

Figure 6.9: Pdu Timing excerpt that may be used to configure LdCom

[TPS_SYST_02027] LdCom: No ISignalPort.timeout reception timeout defined

Upstream requirements: RS_SYST_00049

⌈Only if the ISignalPort which the ISignalTriggering is referring to has no ISignalPort.timeout defined and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02164] LdCom: No ISignalPort.firstTimeout reception timeout defined

Upstream requirements: RS_SYST_00049

⌈Only if the ISignalPort which the ISignalTriggering is referring to has no ISignalPort.firstTimeout defined and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_02028] LdCom: No ISignalPort.dataFilter defined

Upstream requirements: RS_SYST_00049

⌈Only if the ISignalPort which the ISignalTriggering is referring to has either

- no ISignalPort.dataFilter defined
- or the DataFilter.dataFilterType = always

and the LdCom module is present, this ISignal shall be handled by LdCom.⌋

[TPS_SYST_03001] LdCom: ISignalIPdu not part of any ISignalIPduGroup

Upstream requirements: RS_SYST_00049

⌈Only if the ISignalIPdu is not referenced by any ISignalIPduGroup in the role iSignalIPdu and the LdCom module is present, this ISignalIPdu shall be handled by LdCom.⌋

[TPS_SYST_02390] Relevance of LdCom spec items for the sender and for the receiver side.

Upstream requirements: RS_SYST_00049

⌈

Spec Item Number	Spec Item Headline	Motivation	Applies to	Model element
[TPS_SYST_02015]	LdCom: only one ISignal mapped to the ISignalIPdu.	LdCom only supports one ISignal per PDU.	Rx + Tx	ISignalToIPduMapping
[TPS_SYST_02016]	LdCom: only Transformer output and UINT8_N or UINT8_DYN supported.	LdCom only supports Byte Array Signals.	Rx + Tx	ISignal
[TPS_SYST_02017]	LdCom: Opaque ISignalToIPduMapping.packingByteOrder.	LdCom only supports Byte Array Signals.	Rx + Tx	ISignalToIPduMapping
[TPS_SYST_02018]	LdCom: ISignalToIPduMapping.startPosition shall be 0.	LdCom only supports Signals starting in the first byte of the PDU.	Rx + Tx	ISignalToIPduMapping
[TPS_SYST_02019]	LdCom: ISignalToIPduMapping.transferProperty shall be triggered or triggeredWithoutRepetition.	LdCom only supports one ISignal per PDU. That signal has to trigger the transmission.	Tx	ISignalToIPduMapping
[TPS_SYST_02020]	LdCom: No IPduTiming.minimumDelay defined.	LdCom does not support event triggered transmission with repetitions.	Tx	ISignalIPdu
[TPS_SYST_02021]	LdCom: ISignalToIPduMapping.updateIndicationBitPosition shall not be defined.	LdCom does not support update bits.	Rx + Tx	ISignalToIPduMapping
[TPS_SYST_02022]	LdCom: Only the transmissionModeTrueTiming defined.	LdCom does not support transmission modes.	Tx	ISignalIPdu
[TPS_SYST_02023]	LdCom: DataFilter "always" if TransmissionModeCondition defined.	LdCom does not support transmission modes.	Tx	ISignalIPdu
[TPS_SYST_02024]	LdCom: No ModeDrivenTransmissionModeCondition defined.	LdCom does not support transmission modes.	Tx	ISignalIPdu
[TPS_SYST_02025]	LdCom: Only EventControlledTiming defined.	LdCom does not support cyclic transmission.	Tx	ISignalIPdu
[TPS_SYST_02026]	LdCom: Only EventControlledTiming with no repetition defined.	LdCom does not support cyclic transmission nor repeated transmission.	Tx	ISignalIPdu
[TPS_SYST_02027]	LdCom: No ISignalPort.timeout reception timeout defined.	LdCom does not support timeout handling.	Rx	ISignalPort
[TPS_SYST_02164]	LdCom: No ISignalPort.firstTimeout reception timeout defined.	LdCom does not support timeout handling.	Rx	ISignalPort
[TPS_SYST_02028]	LdCom: No ISignalPort.dataFilter defined.	LdCom does not support timeout handling.	Rx	ISignalPort
[TPS_SYST_03001]	LdCom: ISignalIPdu not part of any ISignalIPduGroup.	LdCom does not support ISignalIPduGroups.	Rx + Tx	ISignalIPdu

6.2.2 Big Endian and Little Endian memory layout of Pdus and Frames

The AUTOSAR system description provide means to specify how the memory layout looks like when signals are packed into Pdus and Pdus are packed into Frames. The layout of Pdus and Frames on different communication systems is out of scope of AUTOSAR. The specification of attributes Bit counting (monotone or sawtooth) and Bit order (decreasing or increasing)[1] is not supported by AUTOSAR. In AUTOSAR these attributes are fixed.

[TPS_SYST_01068] Bit Counting in AUTOSAR ⌈The Bit counting shall always be considered as "sawtooth".⌋

[TPS_SYST_01069] Bit Order in AUTOSAR ⌈The bit order shall always be considered as "Decreasing".⌋

When a signal is mapped into a Pdu only the packingByteOrder affects the memory layout of the signal inside the Pdu beginning with it's start bit position.

Little endian stores the least significant byte first and begins with the least significant bit, i.e. loworder bit in the sequence (the least significant bit serves as start bit).

Big endian stores the most significant byte first and begins with the most significant bit, i.e. the bit with the greatest numerical value (the most significant bit serves as start bit).

In both cases the bit positions in the mapped signals increase with the bit positions in the ISignalIPdu such that the bit 2^0 is mapped to position n in the ISignalIPdu and bit 2^1 is mapped to position n+1 and so on.

Example 6.10 shows the memory layout for Little Endian and Big Endian if an ISignal with a length of 10 bits is mappped into a Pdu. The start bit position is 5.

Little Endian byte order:

Byte	0								1							
Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
Signal	2^2	2^1	2^0	-	-	-	-	-	-	2^9	2^8	2^7	2^6	2^5	2^4	2^3

Big Endian byte order:

Byte	0								1							
Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
Signal	-	-	2^9	2^8	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	-	-	-	-

Figure 6.10: PackingByteOrder Example

[1] More details about Bit counting and Bit order can be found in ASAM FIBEX [8].

The following examples are showing the mapping of Pdus into Frames.

The first example in Figure 6.11 for little endian shows a Frame with four bytes that contains a single Pdu that is two bytes long. The PduToFrameMapping.startPosition is defined with 8 and since the packingByteOrder is set to mostSignificantByteLast the startPosition denotes the least significant bit of the Pdu in the Frame. The bit position of the mapped Pdu increases with the bit positions in the Frame such that the bit 2^0 is mapped to position n in the ISignalIPdu and bit 2^1 is mapped to position n+1 and so on.

Please note that the Pdus are byte aligned in a Frame and only the values 0, 8, 16, 24,... (for little endian) and 7, 15, 23, ... (for big endian) for PduToFrameMapping.startPosition are allowed.

Figure 6.11 also shows that the Pdu contains three ISignals. The first ISignal has the ISignalToIPduMapping.startPosition defined as 0 and is 5 bits long. The bitposition of the second signal is 5 and the length is 10 bits. And the third signal has the bitposition 15 and is only 1 bit long. Since the ISignalToIPduMapping.packingByteOrder is defined with mostSignificantByteLast as well the startPosition of the ISignals denotes the least significant bit of the ISignal in the Pdu.

Little Endian byte order:

Signal layout in Pdu:

Byte	1								2							
Bit	15	14	13	12	11	10	9	8	23	22	21	20	19	18	17	16
Signal	2^2	2^1	2^0	2^4	2^3	2^2	2^1	2^0	2^0	2^9	2^8	2^7	2^6	2^5	2^4	2^3
Pdu bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

Pdu layout in Frame:

Byte	0								1								2								3							
Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
Pdu	-	-	-	-	-	-	-	-	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	-	-	-	-	-	-	-	-

Figure 6.11: PackingByteOrder Example

The second example in Figure 6.12 for big endian shows again a Frame with four bytes that contains a single Pdu that is two bytes long. The PduToFrameMapping.startPosition is defined with 15 and since the packingByteOrder is set to mostSignificantByteFirst the startPosition denotes the most significant bit of the Pdu in the Frame.

Figure 6.12 also shows that the Pdu contains three ISignals. The first ISignal has the ISignalToIPduMapping.startPosition defined as 7 and is 5 bits long. The bitposition of the second signal is 2 and the length is 10 bits. And the third signal has the bitposition 8 and is only 1 bit long. Since the ISignalToIPduMapping.packingByteOrder is defined with mostSignificantByteFirst as well the startPosition of the ISignals denotes the most significant bit of the ISignal in the Pdu.

Big Endian byte order:

Signal layout in Pdu:

Byte	1								2							
Frame bit	15	14	13	12	11	10	9	8	23	22	21	20	19	18	17	16
Signal	2^4	2^3	2^2	2^1	2^0	2^9	2^8	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	2^0
Pdu bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

Pdu layout in Frame:

Byte	0								1							
Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
Pdu	-	-	-	-	-	-	-	-	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8

Byte	2								3							
Bit	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
Pdu	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	-	-	-	-	-	-	-	-

Figure 6.12: PackingByteOrder Example

Please note that the positioning of SegmentPositions in a MultiplexedIPdu works in the exact same way. The examples in Figure 6.11 and Figure 6.12 can be taken as well as an example for a MultiplexedIPdu where the 1 bit signal defines the selectorField and the other two signals represent segments defined for the DynamicPart.

6.3 PDUs

The chapter introduces the different Pdu types that are supported in the AUTOSAR Architecture and by the AUTOSAR Meta-Model.

The PDU Router is responsible only for the routing of IPdus. Other Pdus that are direct specializations of the Pdu meta-class are not routed by the PDU Router.

UserDefinedPdus and UserDefinedIPdus are used to describe PDU-based communication over Complex Drivers. Chapter 6.14 provides a more detailed description of CDDs.

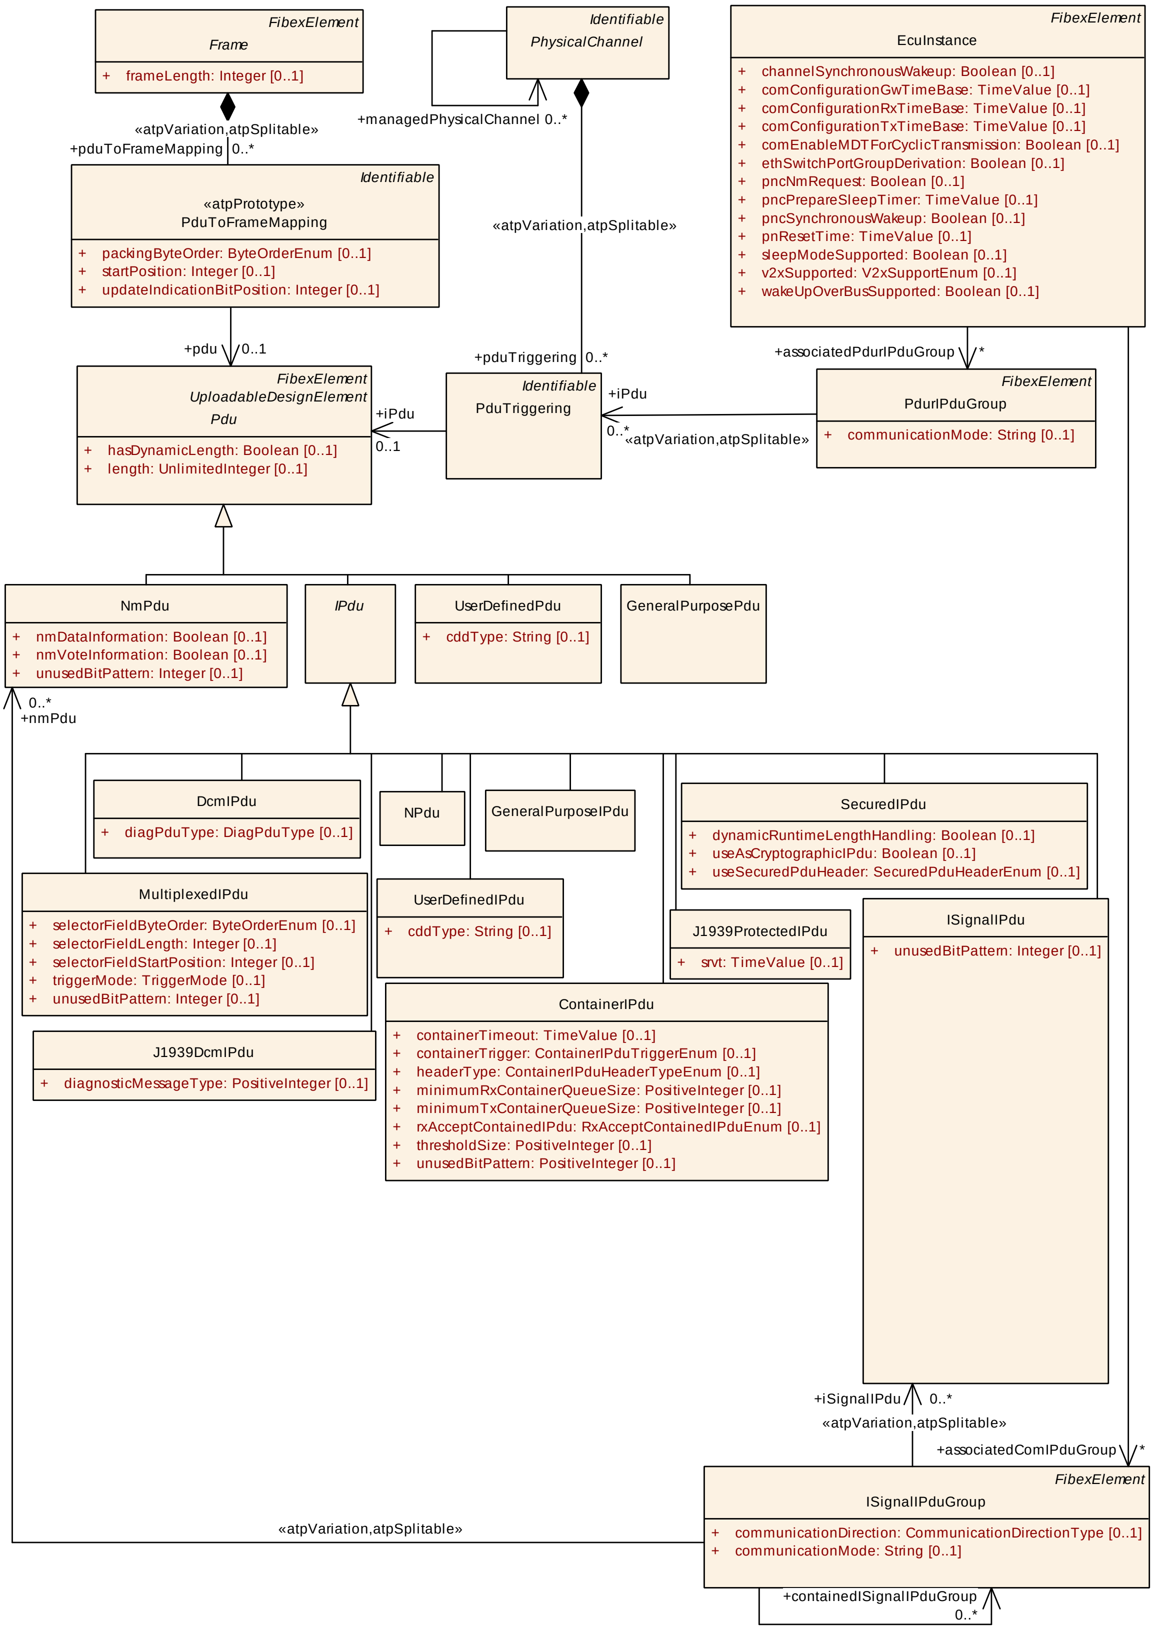

Figure 6.13: Pdus and the mapping into Frames (FibexCore: PDUOverview)

The PduToFrameMapping element describes the mapping of Pdus to Frames and defines the position of a Pdu within a Frame. By using different PduToFrameMappings it is possible to use the same Pdu in different Frames.

[constr_3516] limitation of Frame.frameLength for CAN L-PDUs

Imposition time: IT_SysDesc

⌈The Frame.frameLength of CAN PDUs shall be restricted to

- 0..8 for classic CAN L-PDUs;
- 0..8, 12, 16, 20, 24, 32, 48, 64 for CAN FD L-PDUs and
- 1..2048 for CAN XL L-PDUs.

⌋

Please note that only a single Pdu is allowed to be mapped into a CanFrame. The Pdu.length of the Pdu that is mapped into the CanFrame cannot be smaller than the CanFrame.frameLength, but is allowed to be larger (see [TPS_SYST_02255]). If the CanFrame is a CAN XL frame (SDU Type other than 0x03h, see Ch. 3.3.1.2.2), the Pdu.length cannot be 0.

A timing description IPduTiming can be aggregated directly by the ISignalIPdu. This timing description can be used for the Configuration of COM Transmission Modes. The PduTriggering describes on which channel the Pdu is transmitted. Timing requirements may be specified with the Timing Extension model. More details are described in chapter 1.4.3. Such Pdu timing requirements needs to be fulfilled by the timing specification on the Frame.

Class	***Pdu*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	Collection of all Pdus that can be routed through a bus interface.			
Base	*ARElement*, *ARObject*, *CollectableElement*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Subclasses	GeneralPurposePdu, *IPdu*, NmPdu, UserDefinedPdu			
Aggregated by	ARPackage.element			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
hasDynamicLength	Boolean	0..1	attr	This attribute defines whether the Pdu has dynamic length (true) or not (false). Please note that the usage of this attribute is restricted by [constr_3448].
length	UnlimitedInteger	0..1	attr	Pdu length in bytes. In case of dynamic length IPdus (containing a dynamical length signal), this value indicates the maximum data length. It should be noted that in former AUTOSAR releases (Rel 2.1, Rel 3.0, Rel 3.1, Rel 4.0 Rev. 1) this parameter was defined in bits. The Pdu length of zero bytes is allowed.

Table 6.17: Pdu

[constr_5249] Existence of Pdu.length

Imposition time: IT_SysDesc

⌈For each Pdu, the attribute length shall exist.⌋

Reason: Bsw modules might buffer the payload of the Pdu and for this purpose the Pdu.length needs to be provided. A second reason is that future extensions of the Pdu can be prepared by setting the length to an appropriate value.

[constr_5321] Value range of Pdu.length

Imposition time: IT_SysDesc

⌈The value of Pdu.length shall be in the range of 0..4294967295 Bytes.⌋

[constr_3448] Restriction for usage of Pdu.hasDynamicLength

Imposition time: IT_SysDesc

⌈The Pdu.hasDynamicLength attribute is only relevant for UserDefinedPdus, UserDefinedIPdus, J1939DcmIPdus.⌋

[TPS_SYST_03085] Pdu qualifies as dynamic length

Upstream requirements: RS_SYST_00030

⌈If a Pdu meets one of the following criteria this Pdu is considered dynamic length:

- ISignalIPdu: At least one dynamic signal mapped to the ISignalIPdu.
- SecuredIPdu and MultiplexedIPdu: At least one of the associated upper layer Pdus has dynamic length.
- ContainerIPdu: Is dynamic if:
  - the headerType is shortHeader or longHeader or
  - the headerType is noHeader and the last contained Pdu has dynamic length.
- NPdu: TP layer takes care of length handling, not visible to application.
- DcmIPdu: always dynamic length.
- NmPdu: always static length.
- GeneralPurposePdu and GeneralPurposeIPdu: Depending on upper layer, which could be: SD, TSync, DoIP, XCP, SomeIpTp, Dlt, IDS.
- Pdu with hasDynamicLength = true

⌋

Class	***IPdu*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	The IPdu (Interaction Layer Protocol Data Unit) element is used to sum up all Pdus that are routed by the PduR.

Table 6.28: UserDefinedIPdu

Class	«atpPrototype» **PduToFrameMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	A PduToFrameMapping defines the composition of Pdus in each frame.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	*Frame*.pduToFrameMapping			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
packingByte Order	ByteOrderEnum	0..1	attr	This attribute defines the order of the bytes of the Pdu and the packing into the Frame. Please consider that [constr_3246] and [constr_3222] are restricting the usage of this attribute.
pdu	Pdu	0..1	ref	Reference to a I-Pdu, N-Pdu or NmPdu that is transmitted in the Frame.
startPosition	Integer	0..1	attr	This attribute describes the bitposition of a Pdu within a Frame. Please note that the absolute position of the Pdu in the Frame is determined by the definition of the packingByte Order attribute. If Big Endian is specified, the start position indicates the bit position of the most significant bit in the Frame. If Little Endian is specified, the start position indicates the bit position of the least significant bit in the Frame. The bit counting in byte 0 starts with bit 0 (least significant bit). The most significant bit in byte 0 is bit 7. The Pdus are byte aligned in a Frame and only the values 0, 8, 16, 24,... (for little endian) and 7, 15, 23, ... (for big endian) are allowed.
update IndicationBit Position	Integer	0..1	attr	Indication to the receivers that the corresponding Pdu was updated by the sender. This attribute describes the position of the update bit in the frame that aggregates this PDUToFrameMapping. Length is always one bit. Note that the exact bit position of the updateIndicationBit Position is linked to the value of the attribute packingByte Order because the method of finding the bit position is different for the values mostSignificantByteFirst and most SignificantByteLast. This means that if the value of packingByteOrder is changed while the value of update IndicationBitPosition remains unchanged the exact bit position of updateIndicationBitPosition within the enclosing Frame still undergoes a change. This attribute denotes the least significant bit for "Little Endian" and the most significant bit for "Big Endian" ▽

△

Class	«atpPrototype» PduToFrameMapping			
				△ packed signals within the IPdu (see the description of the packingByteOrder attribute). In AUTOSAR the bit counting is always set to "sawtooth" and the bit order is set to "Decreasing". The bit counting in byte 0 starts with bit 0 (least significant bit). The most significant bit in byte 0 is bit 7.

Table 6.29: PduToFrameMapping

[constr_9195] Existence of PduToFrameMapping.packingByteOrder

Imposition time: IT_SysDesc

⌈For each PduToFrameMapping, the attribute packingByteOrder shall exist.⌋

[constr_9196] Existence of PduToFrameMapping.startPosition

Imposition time: IT_SysDesc

⌈For each PduToFrameMapping, the attribute startPosition shall exist.⌋

[constr_9197] Existence of PduToFrameMapping.pdu

Imposition time: IT_SysDesc

⌈For each PduToFrameMapping, the reference to Pdu in the role pdu shall exist.⌋

[constr_3246] Frame.packingByteOrder mix within a Frame is not allowed

Imposition time: IT_SysDesc

⌈All PduToFrameMappings within a Frame shall have the same packingByteOrder value.⌋

Please note that the absolute position (bit-position) of the Pdu in the Frame is determined by the definition of the packingByteOrder attribute. The Pdus are byte aligned in a Frame and the values 0, 8, 16, 24,... (for little endian) and 7, 15, 23, ... (for big endian) are allowed. For reasons of simplicity a mix of the packingByteOrder is not allowed.

[constr_3222] No ByteOrderEnum.opaque allowed for PduToFrameMapping.packingByteOrder

Imposition time: IT_SysDesc

⌈The values of PduToFrameMapping.packingByteOrder are restricted to ByteOrderEnum.mostSignificantByteFirst and ByteOrderEnum.mostSignificantByteLast. I.e. the value ByteOrderEnum.opaque is not allowed.⌋

Class	IPduTiming			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	AUTOSAR COM provides the possibility to define two different TRANSMISSION MODES for each IPdu. The Transmission Mode of an IPdu that is valid at a specific point in time is selected using the values of the signals that are mapped to this IPdu. For each IPdu a Transmission Mode Selector is defined. The Transmission Mode Selector is calculated by evaluating the conditions for a subset of signals (class TransmissionModeCondition in the System Template). The Transmission Mode Selector is defined to be true, if at least one Condition evaluates to true and is defined to be false, if all Conditions evaluate to false.			
Base	*ARObject*, *Describable*			
Aggregated by	ISignalIPdu.iPduTimingSpecification			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
minimumDelay	TimeValue	0..1	attr	Minimum Delay in seconds between successive transmissions of this I-PDU, independent of the Transmission Mode.
transmissionModeDeclaration	TransmissionModeDeclaration	0..1	aggr	AUTOSAR COM allows configuring statically two different transmission modes for each I-PDU (True and False). The Transmission Mode Selector evaluates the conditions for a subset of signals and decides the transmission mode. It is possible to switch between the transmission modes during runtime.

Table 6.30: IPduTiming

Class	PduTriggering			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	The PduTriggering describes on which channel the IPdu is transmitted. The Pdu routing by the PduR is only allowed for subclasses of IPdu. Depending on its relation to entities such channels and clusters it can be unambiguously deduced whether a fan-out is handled by the Pdu router or the Bus Interface. If the fan-out is specified between different clusters it shall be handled by the Pdu Router. If the fan-out is specified between different channels of the same cluster it shall be handled by the Bus Interface.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	*PhysicalChannel*.pduTriggering			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
iPdu	Pdu	0..1	ref	Reference to the Pdu for which the PduTriggering is defined. One I-Pdu can be triggered on different channels (PduR fan-out). The Pdu routing by the PduR is only allowed for subclasses of IPdu. Nevertheless is the reference to the Pdu element necessary since the PduTriggering element is also used to specify the sending and receiving connections to Ecu Ports.
iPduPort	IPduPort	*	ref	References to the IPduPort on every ECU of the system which sends and/or receives the I-PDU. References for both the sender and the receiver side shall be included when the system is completely defined.

▽

△

Class	PduTriggering			
iSignal Triggering	ISignalTriggering	*	ref	This reference provides the relationship to the ISignal Triggerings that are implemented by the PduTriggering. The reference is optional since no ISignalTriggering can be defined for DCM and Multiplexed Pdus. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=iSignalTriggering.iSignalTriggering, iSignal Triggering.variationPoint.shortLabel vh.latestBindingTime=postBuild
secOcCrypto Mapping	SecOcCryptoService Mapping	0..1	ref	This reference identifies the crypto profile applicable to the usage (send, receive) of the also referenced Secured IPdu. Obviously, this reference is only applicable if the Pdutriggering also references a SecuredIPdu in the role i Pdu.
triggerIPduSend Condition	TriggerIPduSend Condition	*	aggr	Defines the trigger for the Com_TriggerIPDUSend API call. Only if all defined TriggerIPduSendConditions evaluate to true (AND associated) the Com_Trigger IPDUSend API shall be called.

Table 6.31: PduTriggering

[constr_9198] Existence of PduTriggering.iPdu

Imposition time: IT_SysDesc

⌈For each PduTriggering, the reference to Pdu in the role iPdu shall exist.⌋

AUTOSAR COM provides a mechanism of starting/stopping COM PDU groups (ISignalIPduGroup). Please note that in a System Model an ISignalIPdu can belong to several ISignalIPduGroups of different EcuInstances. So it is not possible to deduce the assignment of an ISignalIPduGroup to an EcuInstance via the iSignalIPdus that are included in the ISignalIPduGroup. The assignment of an ISignalIPduGroup to an EcuInstance is therefore realized with the EcuInstance.associatedComIPduGroup reference.

Please note that the EcuInstance.associatedComIPduGroup reference is only used to assign the top-level ISignalIPduGroups to an EcuInstance. The assignment of the containedISignalIPduGroups to an EcuInstance is done via the aggregating ISignalIPduGroup that in turn is referenced by an EcuInstance.

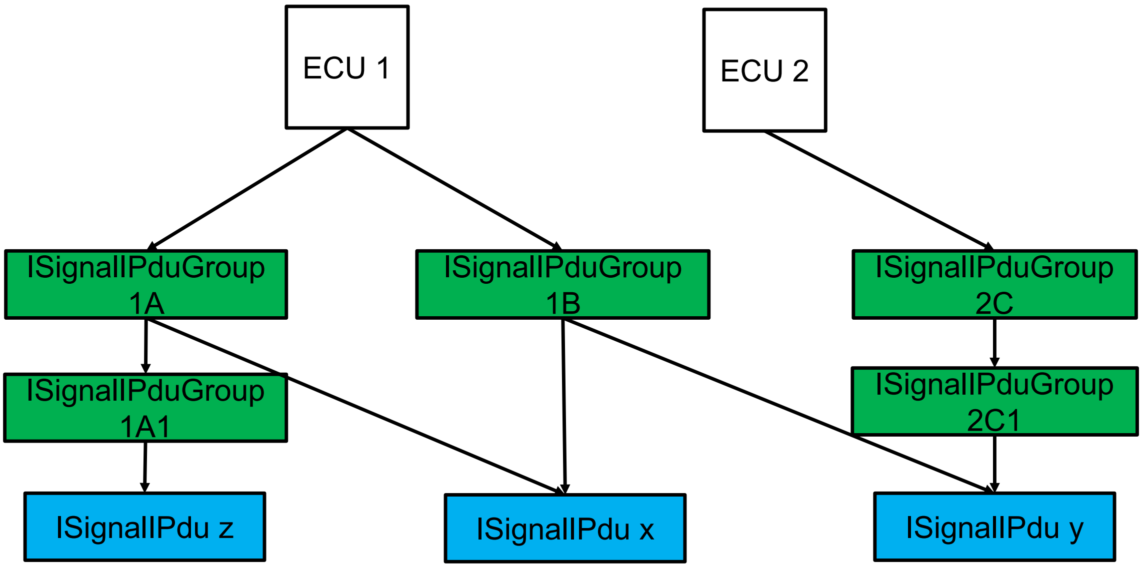

Figure 6.14: Example for ISignalIPduGroups and their assignment to EcuInstances

Class	**ISignalIPduGroup**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	The AUTOSAR COM Layer is able to start and to stop sending and receiving configurable groups of I-Pdus during runtime. An ISignalIPduGroup contains either ISignalIPdus or ISignalIPduGroups. **Tags:** atp.recommendedPackage=ISignaliPduGroup

communication Mode	String	0..1	attr	This attribute defines the use-case for this PduRIPdu Group. For example, in a diagnostic mode all IPdus - which are not involved in diagnostic - are disabled. The use cases are not limited to a fixed enumeration and can be specified as a string.
iPdu	PduTriggering	*	ref	Reference to a set of IPdus, which are contained in the PduR I-Pdu Group. If an IPdu is routed by the PduR to different destinations (PduR fan-out) than an Pdu Triggering for each destination is created in the System Template. To enable/disable a specific destination the PdurIPduGroup refers to the PduTriggering. atpVariation: The content of a PduR I-Pdu group can vary (->vehicle modes). **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=iPdu.pduTriggering, iPdu.variationPoint.short Label vh.latestBindingTime=postBuild

Table 6.34: PdurIPduGroup

6.3.1 ContainerIPdu

IPdu collection is used to transport several (smaller) IPdus in one (large) ContainerIPdu. A possible use case for example is the extended payload size for Ethernet and CanFd in combination with the limited payload of Can and Lin, where Pdus from a Can network shall be routed onto an Ethernet network and then back to a Can again.

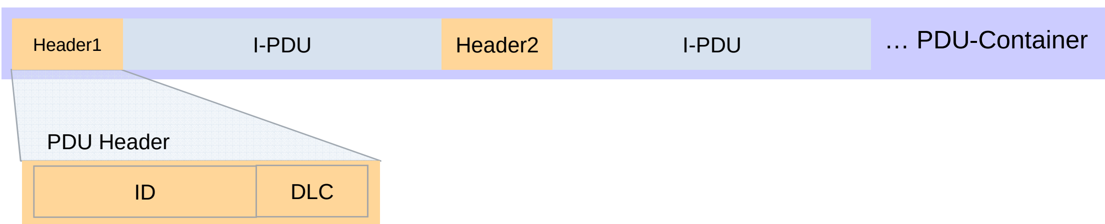

Figure 6.15: Layout of a ContainerIPdu if HeaderMode is used

For each IPdu which is put inside a ContainerIPdu, a header may be provided which determines which IPdu is contained (ContainedIPduProps.headerIdLongHeader or headerIdShortHeader) and what the size of that IPdu is (

DLC during runtime). With this header mode the receivers are able to extract the individual contained IPdus again. As an alternative option to the usage of headers a statically configured layout of IPdus in the ContainerIPdu is supported.

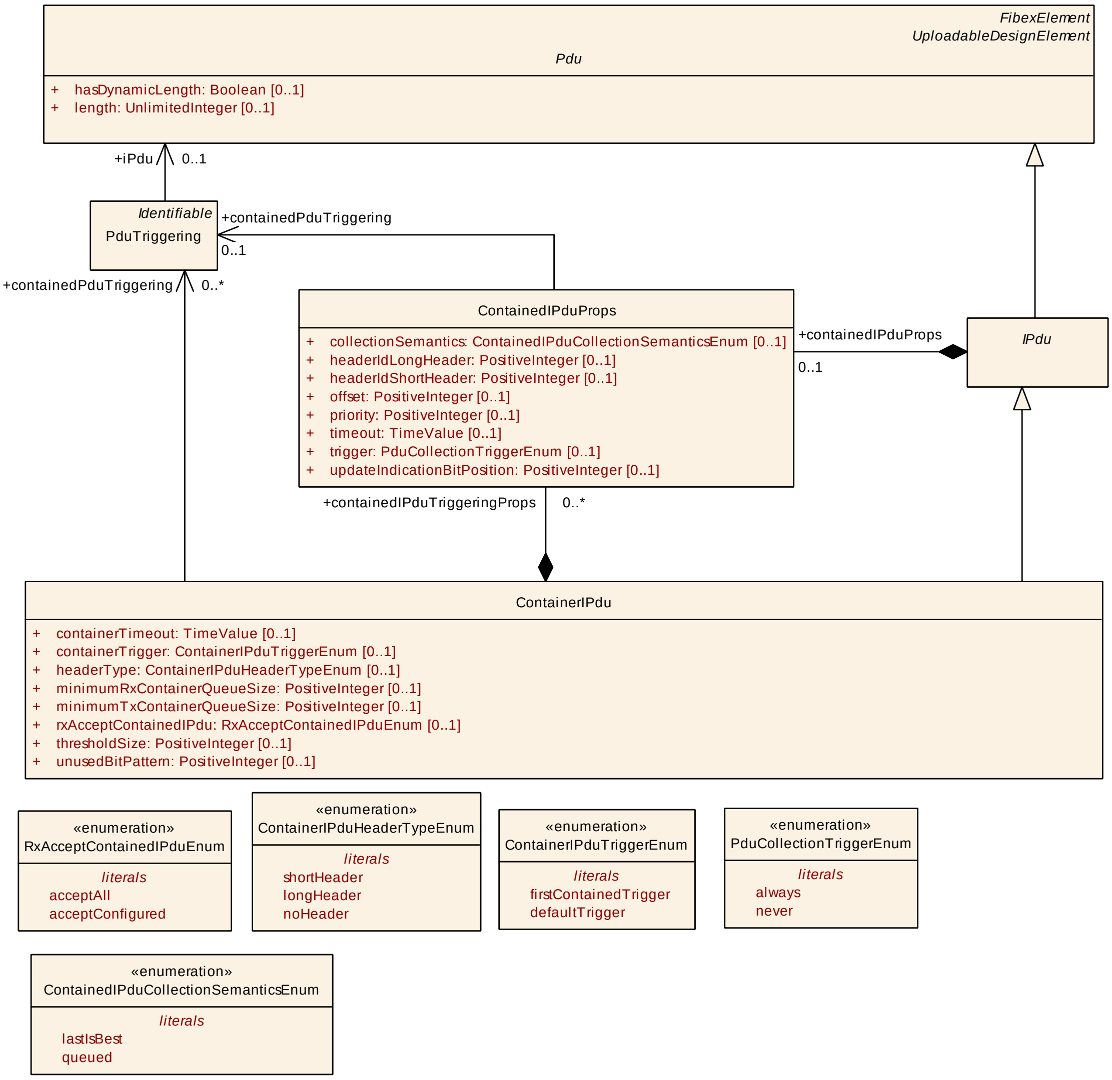

Figure 6.16: ContainerIPdu with ContainedIPduProps

Class	**ContainerIPdu**

never	Pdu will be buffered and will not trigger the transmission of the data. **Tags:** atp.EnumerationLiteralIndex=1

Table 6.41: PduCollectionTriggerEnum

[TPS_SYST_02062] Allowed ContainedIPduProps.headerIdLongHeader and ContainedIPduProps.headerIdShortHeader values

Upstream requirements: RS_SYST_00055

⌈ContainedIPduProps.headerIdLongHeader and ContainedIPduProps.headerIdShortHeader shall be restricted to values different from 0 (all bits of the value set to 0).⌋

Since the header information is larger than 8 bit the byte ordering of the header inside the ContainerIPdu needs to be defined. This is done at System level. Thus all ContainerIPdus have the header information in the same byte order within one System.

[TPS_SYST_02063] Byte order of ContainerIPdu header information

Upstream requirements: RS_SYST_00055

⌈The System.containerIPduHeaderByteOrder defines in which byte order the header information shall be put into the ContainerIPdu.⌋

[constr_3140] No ByteOrderEnum.opaque allowed for System.containerIPduHeaderByteOrder

Imposition time: IT_SysDesc

⌈The values of System.containerIPduHeaderByteOrder are restricted to ByteOrderEnum.mostSignificantByteFirst and ByteOrderEnum.mostSignificantByteLast. I.e. the value ByteOrderEnum.opaque is not allowed.⌋

The following assumptions lead to the modeling of the ContainerIPdu structure:

- **[TPS_SYST_02097] Basic definition of contained IPdus**

  Upstream requirements: RS_SYST_00055

  ⌈Every IPdu for which:

  - IPdu.containedIPduProps are defined or
  - the PduTriggering is referenced in the role containedIPduTriggeringProps

  can be collected inside a ContainerIPdu.⌋

- **[TPS_SYST_02098] Header id and header type of a contained IPdu**

  Upstream requirements: RS_SYST_00055

  ⌈A contained IPdu shall always have the same headerId per header type (long or short header), regardless in which ContainerIPdu it is collected. If noHeader is set then the contained IPdu does not need to have a headerId.⌋

- **[TPS_SYST_02100] Relation between ContainerIPdu and contained IPdus on receiver side**

  Upstream requirements: RS_SYST_00055

  ⌈On receiver side, it is not necessarily required to statically define which IPdus may be contained inside a ContainerIPdu if the header mode is used. Thus it would be possible to update the senders of ContainerIPdus and put different or additional IPdus inside.⌋

[constr_5362] Relation between ContainerIPdu and contained PduTriggerings on sender side

Imposition time: IT_SysDesc

⌈In the scope of one EcuInstance, if a PduTriggering has a reference to an IPduPort where attribute communicationDirection is set to the value out, then that PduTriggering shall only be referenced at most once by any of

- ContainerIPdu.containedPduTriggering
- ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering.

⌋

The ContainerIPdu defines which IPdus may be collected inside that ContainerIPdu (ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering). Dynamic assignment of a contained IPdu to different ContainerIPdus during run-time is not supported by the IPdu multiplexer. Nevertheless it is allowed to collect an IPdu in several ContainerIPdus since each of those ContainerIPdus can be transmitted individually (on the same or on a different PhysicalChannel).

If a ContainerIPdu is transmitted on different PhysicalChannels this can be described in a System Description by a single Pdu element that is referenced by PduTriggerings of the different PhysicalChannels. Details on the ownership of PduTriggerings can be found in section 6.1.1.

[constr_3141] Only IPdus shall be part of a ContainerIPdu

Imposition time: IT_SysDesc

⌈The PduTriggering which is referenced in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering shall refer to a subclass of an IPdu in the role PduTriggering.iPdu.⌋

Only subclasses of IPdus are handled by the PduR and therefore are available for the ContainerIPdu.

For the sender side this assignment defines which IPdus may be collected inside this ContainerIPdu. For the receiver side this assignment may be omitted if ContainerIPdu.rxAcceptContainedIPdu is set to RxAcceptContainedIPduEnum.acceptAll.

[TPS_SYST_02064] Reception acceptance of contained IPdus

Upstream requirements: RS_SYST_00055

⌈ContainerIPdu.rxAcceptContainedIPdu defines for the receiver side whether the list of ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering is a closed set.

If ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptConfigured, only those IPdus (based on headerId) which are referenced by this ContainerIPdu in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering are extracted from this ContainerIPdu.

If ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptAll, the IPdus (based on headerId) which are referenced by this ContainerIPdu in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering are expected inside this ContainerIPdu but also any other IPdu is extracted which is referenced by any other ContainerIPdu.rxAcceptContainedIPdu with RxAcceptContainedIPduEnum.acceptAll set.⌋

Thus all referenced IPdus which are referenced from ContainerIPdu.rxAcceptContainedIPdu with RxAcceptContainedIPduEnum.acceptAll form the set of IPdus which are considered for the reception of ANY ContainerIPdu with ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptAll.

For the receiver side ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering may be omitted if ContainerIPdu.rxAcceptContainedIPdu is set to RxAcceptContainedIPduEnum.acceptAll. Such a ContainerIPdu will accept any of the contained IPdus from the acceptAll IPdu set if they have the headerId (headerIdShortHeader or headerIdLongHeader) defined by the ContainerIPdu.headerType configured.

There are use-cases where several IPdus with identical content are transported on the vehicle networks. One motivation to design the communication structure like this is that the communication timing attributes may be different and thus need to be represented by different ISignalIPdus (i.e. different ISignalIPdu.iPduTimingSpecification, e.g. to support the transmission on Can and Fr networks with different transmission modes). When the content of the IPdus is identical they can be transported using the same header Id. Thus it is transparent for the receiver via which channel a specific IPdu arrived in case of ContainerIPdu with acceptAll setting.

In such a setup it may occur that several PduTriggerings for IPdus with identical header IDs are defined as candidates for the set of IPdus which are considered for the reception of acceptAll ContainerIPdus. This is considered a valid setup and shall be resolved during derivation to ECU Configuration.

The Ecu Configuration for ContainerIPdu.rxAcceptContainedIPdu = acceptAll uses a set of Contained Rx Pdus without a relation to Container Pdus. This set is defined during derivation of the Ecu Configuration from the System Description. If duplicates occur they are only included once in the set of Contained Rx Pdus.

In such a case there is additional information required to select which of these PduTriggerings shall be taken for the configuration and which shall be omitted.

[TPS_SYST_02196] PduTriggering is referenced by several ContainerIPdus

Upstream requirements: RS_SYST_00055

⌈In case a PduTriggering is referenced in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering by several ContainerIPdus with ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptAll and has a reference to an IPduPort with direction IN then this PduTriggering shall only be considered once for the set of IPdus which are considered for the reception of acceptAll ContainerIPdus.⌋

[constr_3403] Usage of ContainerIPdu.rxAcceptContainedIPdu if noHeader is used

Imposition time: IT_SysDesc

⌈If the ContainerIPdu.headerType is set to noHeader then the ContainerIPdu.rxAcceptContainedIPdu attribute value shall be set to acceptConfigured.⌋

[TPS_SYST_03014] Transmission triggering by the first contained IPdu put into a ContainerIPdu

Upstream requirements: RS_SYST_00055

⌈The attribute ContainerIPdu.containerTrigger determines whether the transmission of a ContainerIPdu shall be requested when the first contained IPdu was put into the ContainerIPdu.

In case containerTrigger equals firstContainedTrigger the transmission of the ContainerIPdu shall be requested when the first contained IPdu is put into the ContainerIPdu.

In case containerTrigger equals defaultTrigger the transmission of the ContainerIPdu shall be requested when the other trigger conditions defined by the ContainerIPdu are fulfilled (e.g. containerTimeout, thresholdSize).⌋

Note: This trigger condition is independent from PduCollectionTriggerEnum.always which is defined for specific IPdus. With the attribute ContainerIPdu.containerTrigger = firstContainedTrigger on the other hand, any contained IPdu will trigger the ContainerIPdu transmission.

Rationale for this trigger condition is the efficient usage (allow the ContainerIPdus to reach a certain fill level) of triggered transmission on time- (containerTrigger typically set to firstContainedTrigger) and event-driven (containerTrigger typically set to defaultTrigger) buses.

The ContainedIPduProps defines a header Id per ContainerIPdu.headerType which shall be used in the Pdu header of the ContainerIPdu in case that the headerType is set to shortHeader or longHeader. In case that the headerType is set to noHeader the layout of IPdus in the ContainerIPdu is statically configured and no header Id is required.

[constr_3454] Unique headerIdLongHeader for acceptConfigured

Imposition time: IT_SysDesc

⌈For a ContainerIPdu with ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptConfigured and ContainerIPdu.headerType = longHeader the following shall apply: All referenced IPdus (via ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering) shall have a unique ContainedIPduProps.headerIdLongHeader within the scope of this ContainerIPdu.⌋

[constr_3455] Unique headerIdShortHeader for acceptConfigured

Imposition time: IT_SysDesc

⌈For a ContainerIPdu with ContainerIPdu.rxAcceptContainedIPdu = RxAcceptContainedIPduEnum.acceptConfigured and ContainerIPdu.headerType = shortHeader the following shall apply: All referenced IPdus (via ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering) shall have a unique ContainedIPduProps.headerIdShortHeader within the scope of this ContainerIPdu.⌋

Note: With [constr_3454] and [constr_3455] it is possible to have the same header Id value received in different ContainerIPdus. It just has to be guaranteed that in the scope of one ContainerIPdu the reception of header Id is unambiguous.

[constr_3142] Mandatory headerIdLongHeader for longHeader

Imposition time: IT_SysDesc

⌈For each IPdu which is assigned to a ContainerIPdu in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering with ContainerIPdu.headerType = longHeader the ContainedIPduProps.headerIdLongHeader shall be defined.⌋

[constr_3143] Mandatory headerIdShortHeader for shortHeader

Imposition time: IT_SysDesc

⌈For each IPdu which is assigned to a ContainerIPdu in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering with ContainerIPdu.headerType = shortHeader the ContainedIPduProps.headerIdShortHeader shall be defined.⌋

[constr_3402] Mandatory offset if noHeader is used

Imposition time: IT_SysDesc

⌈For each IPdu which is assigned to a ContainerIPdu in the role ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering with ContainerIPdu.headerType = noHeader the ContainedIPduProps.offset shall be defined.⌋

[constr_3404] Usage of ContainedIPduProps.updateIndicationBitPosition

Imposition time: IT_SysDesc

⌈ContainedIPduProps.updateIndicationBitPosition is only allowed to be set to a value if the headerType of the ContainerIPdu that contains the IPdu with ContainerIPdu.containedPduTriggering or ContainerIPdu.containedIPduTriggeringProps.containedPduTriggering is set to noHeader.⌋

[constr_3405] Dynamic Length IPdu inside of a static configured ContainerIPdu

Imposition time: IT_SysDesc

⌈Only the last contained IPdu (according to the ContainedIPduProps.offset) of a ContainerIPdu with static container layout (i.e., a ContainerIPdu with headerType set to noHeader) is allowed to be a dynamic length IPdu (i.e, a contained IPdu that at runtime may exhibit a length different from the one statically configured via Pdu.length of the respective Pdu). All other contained IPdus of a ContainerIPdu with static container layout have to be static length IPdus.⌋

[TPS_SYST_02065] Contained IPdu specific transmission timeout

Upstream requirements: RS_SYST_00055

⌈The IPdu specific transmission timeout can be specified at ContainedIPduProps.timeout. If no ContainedIPduProps.timeout is provided the timeout from the ContainerIPdu shall be used (ContainerIPdu.containerTimeout).⌋

The case where neither the ContainerIPdu.containerTimeout nor the ContainedIPduProps.timeout is provided, will result in no time-based triggering of ContainerIPdus which might lead to long delays or no transmission at all if no other sending condition for this ContainerIPdu does occur (e.g. no further IPdu is collected inside this ContainerIPdu).

[TPS_SYST_02066] ContainerIPdu.thresholdSize

Upstream requirements: RS_SYST_00055

⌈The attribute ContainerIPdu.thresholdSize defines the threshold when a ContainerIPdu shall be triggered for transmission. If the payload size of the ContainerIPdu exceeds the value of thresholdSize this ContainerIPdu shall be transmitted.⌋

Note: The ContainerIPdu.thresholdSize supports the definition of a transmission threshold which takes the data transmission model of the communication into account. Especially when operating with variable length IPdus, only the maximum length of these IPdus is defined in the System Description. Only having the maximumLength information it is not possible to derive a sensible threshold for the ContainerIPdu this variable length IPdu is collected in. Thus a ContainerIPdu would wait for further contained IPdus. Using a transmission model it can be calculated that the average size contained IPdu will not fit into that ContainerIPdu anymore and provide this as a requirement in ContainerIPdu.thresholdSize.

Another use case for the ContainedIPduProps is to support the usage of optimized trigger transmit collection of IPdus in ContainerIPdus. Therefore it is necessary to distinguish between contained IPdus with lastIsBest (will be fetched via trigger transmit just before the transmission executes) and those with queued semantics (will instantly be stored in the context of the transmit API). This distinction is possible on the level of single contained IPdus with the attribute collectionSemantics.

For all intents and purposes, the different handling of contained IPdus depending on the semantics is supported by the attribute ContainedIPduProps.collectionSemantics that allows the individual setting of the intended semantics per contained IPdu.

[constr_3517] Consistent setting of ContainedIPduProps.collectionSemantics in the context of one ContainerIPdu

Imposition time: IT_SysDesc

⌈The value of the attribute ContainedIPduProps.collectionSemantics shall be identical for all contained IPdus within the context of a given ContainerIPdu.⌋

[constr_3144] Mandatory IPdu.containedIPduProps for contained IPdus

Imposition time: IT_SysDesc

⌈For each IPdu which is assigned to a ContainerIPdu in the role ContainerIPdu.containedPduTriggering, the IPdu.containedIPduProps shall be defined.⌋

ContainedIPduProps is optional and may be ignored in case the IPdu is not mapped into a ContainerIPdu. A use-case is that an IPdu is fan-out in the PduR and one PduTriggering is part of a ContainerIPdu while the other PduTriggering is directly transported via a bus interface.

Another case where ContainedIPduProps aggregated at the IPdu are ignored is described in [TPS_SYST_02372].

[constr_3488] Value range of ContainedIPduProps.priority

Imposition time: IT_SysDesc

⌈If defined, the value of ContainedIPduProps.priority shall be in the range of 0..255.⌋

[constr_3489] ContainedIPduProps.priority is only applicable if a ContainerIPdu header is used

Imposition time: IT_SysDesc

⌈ContainedIPduProps.priority is only applicable if the headerType of the ContainerIPdu is set to shortHeader or longHeader.⌋

[constr_3490] ContainedIPduProps.priority is only applicable if collectionSemantics is set to lastIsBest

Imposition time: IT_SysDesc

⌈ContainedIPduProps.priority is only applicable if ContainedIPduProps.collectionSemantics is set to lastIsBest.⌋

6.3.2 SecuredIPdu

AUTOSAR supports an authentication mechanism for critical data on the level of Pdus.

[TPS_SYST_02060] SecuredIPdus

Upstream requirements: RS_SYST_00054

⌈SecuredIPdu shall be used to describe an IPdu that is protected against unauthorized manipulation and replay attacks.⌋

Please note that several SecuredIPdus may exist with the same dataId value since the same data may be transported on different channels.

[TPS_SYST_02148] Meaning of useAsCryptographicIPdu that is not set or set to false

Upstream requirements: RS_SYST_00054

⌈If useAsCryptographicIPdu is not set or set to false the SecuredIPdu contains the payload of an Authentic IPdu supplemented by additional Authentication Information (Freshness Counter and an Authenticator).⌋

[TPS_SYST_02149] Meaning of useAsCryptographicIPdu that is set to true

Upstream requirements: RS_SYST_00054

⌈If useAsCryptographicIPdu is set to true the SecuredIPdu contains the Authenticator for a payload that is transported in a separate message. The separate Authentic IPdu is described by the PduTriggering that is referenced with the payload reference.⌋

The attribute useAsCryptographicIPdu decides whether one single Pdu or two Pdus are transferred on the communication bus. In either case always two IPdus shall be modeled:

- SecuredIPdu with a PduTriggering
- payload IPdu with a PduTriggering

[TPS_SYST_02172] Modeling of SecuredIPdu in case useAsCryptographicIPdu is set to false

Upstream requirements: RS_SYST_00054

⌈If the useAsCryptographicIPdu is set to false only the SecuredIPdu shall be either

- mapped into a Frame by the PduToFrameMapping or
- mapped into a StaticSocketConnection or
- assigned to an AbstractServiceInstance via PduActivationRoutingGroup that references the SoConIPduIdentifier that represents the SecuredIPdu or
- assigned to a ContainerIPdu.

⌋

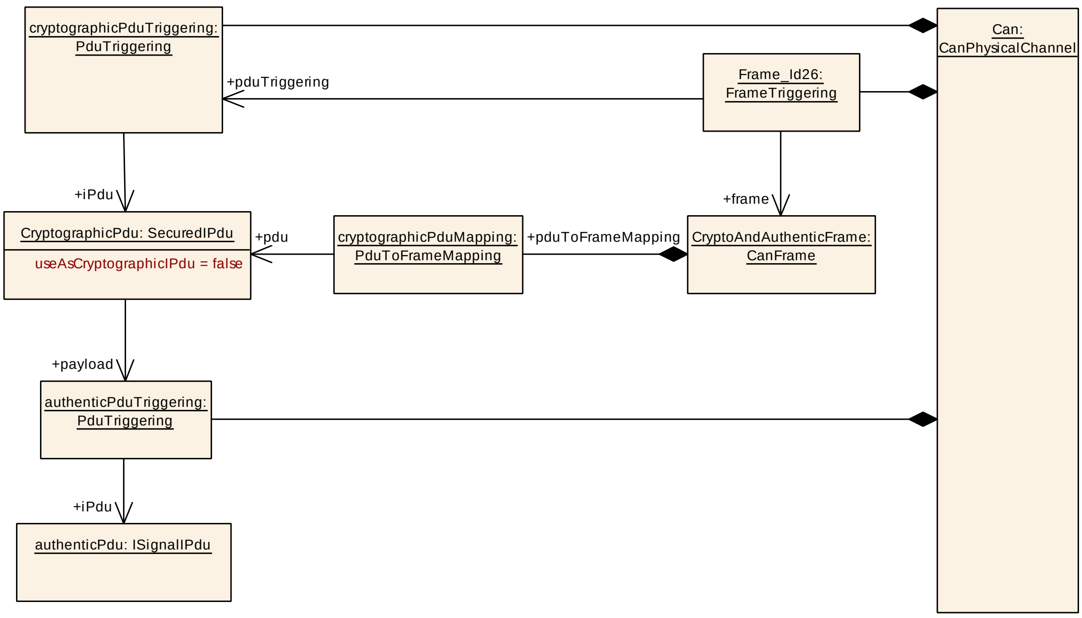

Figure 6.17: Example for the modeling of SecuredIPdu with useAsCryptographicIPdu set to false

If a SecuredIPdu is transmitted on different PhysicalChannels this can be described in a System Description by a single SecuredIPdu element that is referenced by PduTriggerings of the different PhysicalChannels. Details on the ownership of PduTriggerings can be found in section 6.1.1.

[TPS_SYST_02173] Modeling of SecuredIPdu in case useAsCryptographicIPdu is set to true

Upstream requirements: RS_SYST_00054

⌈If the useAsCryptographicIPdu is set to true then the SecuredIPdu and the payload IPdu shall be either

- mapped into Frames by the PduToFrameMapping or
- assigned to StaticSocketConnection or
- assigned to AbstractServiceInstances via PduActivationRoutingGroup that references the SoConIPduIdentifiers that represent the SecuredIPdu and the payload IPdu or
- assigned to ContainerIPdus.

⌋

[constr_5259] PduTriggerings and FrameTriggerings of SecuredIPdu with useAsCryptographicIPdu = true

Imposition time: IT_SysDesc

⌈In case that a SecuredIPdu is defined with useAsCryptographicIPdu = true as described by [TPS_SYST_02173] then:

- the PduTriggering of the AuthenticPdu
- the PduTriggering of the CryptographicPdu
- the FrameTriggering that references the Frame to which the AuthenticPdu is mapped
- the FrameTriggering that references the Frame to which the CryptographicPdu is mapped

shall be aggregated by the same PhysicalChannel.⌋

[TPS_SYST_02361] PduR Fan-out of SecuredIPdu with useAsCryptographicIPdu = true ⌈If a PduR fan-out of a SecuredIPdu with useAsCryptographicIPdu = true is defined then [constr_5259] shall be considered on all PhysicalChannels on which the SecuredIPdu is transmitted.⌋

In other words the PduTriggerings of the AuthenticPdu and the CryptographicPdu and the FrameTriggerings that reference the Frames to which the AuthenticPdu and CryptographicPdu are mapped need to be defined on all PhysicalChannels on which the SecuredIPdu is transmitted.

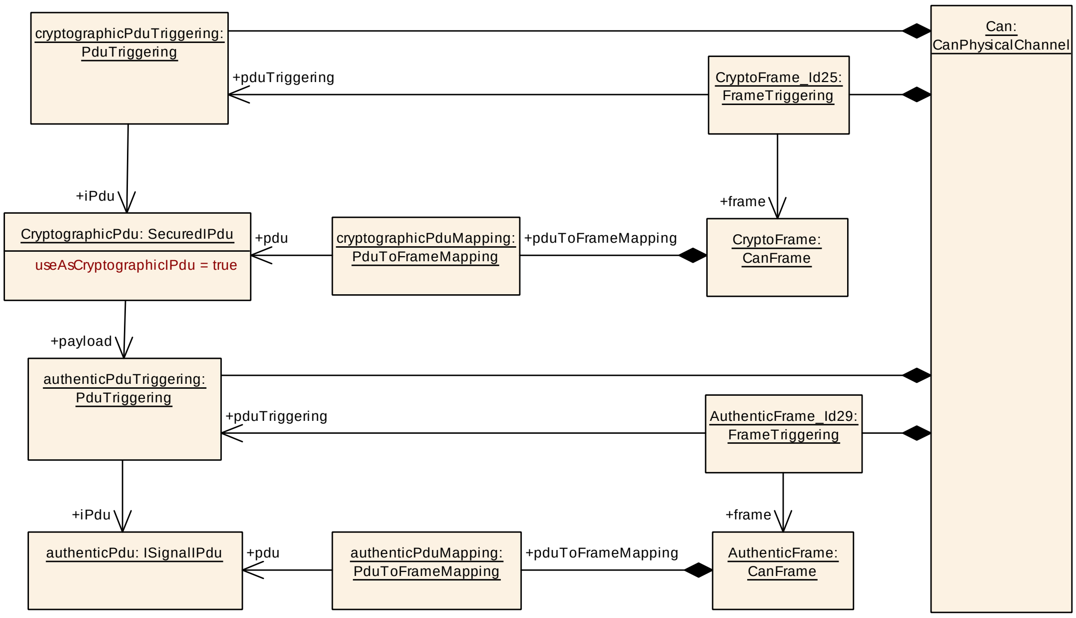

Figure 6.18: Example for the modeling of SecuredIPdu with useAsCryptographicIPdu set to true

Please note that [TPS_SYST_02059] defines that the PduTriggerings of the SecuredIPdu and PduTriggerings of the payload IPdu shall both reference IPduPorts.

A SecuredIPdu defines freshness properties by referencing the reusable SecureCommunicationFreshnessProps in the role freshnessProps. The authentication properties are defined by reusable SecureCommunicationAuthenticationProps that are referenced in the role authenticationProps. Configuration settings that are specific to the SecuredIPdu are defined in SecureCommunicationProps.

Please note that if the SecuredIPdu does not reference the SecureCommunicationFreshnessProps in the role freshnessProps the freshness value will not be included in the SecuredIPdu.

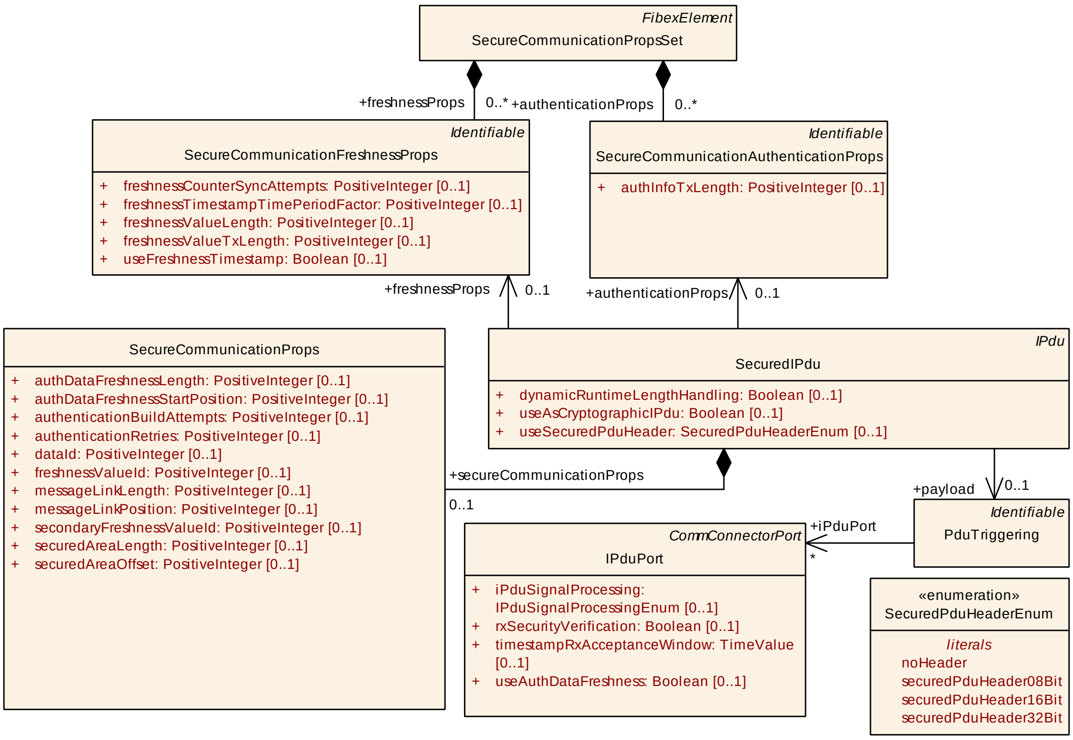

Figure 6.19: SecuredIPdu with SecureCommunicationProps

Class	**SecuredIPdu**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	If useAsCryptographicPdu is not set or set to false this IPdu contains the payload of an Authentic IPdu supplemented by additional Authentication Information (Freshness Counter and an Authenticator). If useAsCryptographicPdu is set to true this IPdu contains the Authenticator for a payload that is transported in a separate message. The separate Authentic IPdu is described by the Pdu that is referenced with the payload reference from this SecuredIPdu. **Tags:** atp.recommendedPackage=Pdus			
Base	*ARElement*, *ARObject*, *CollectableElement*, *FibexElement*, *IPdu*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Pdu*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*

△

Class	**SecuredIPdu**			
secure Communication Props	SecureCommunication Props	0..1	aggr	Specific configuration properties for this SecuredIPdu.
useAs Cryptographic IPdu	Boolean	0..1	attr	If this attribute is set to true the SecuredIPdu contains the Authentication Information for an AuthenticIPdu that is transmitted in a separate message. The AuthenticIPdu contains the original payload, i.e. the secured data. If this attribute is set to false this SecuredIPdu contains the payload of an Authentic IPdu supplemented by additional Authentication Information.
useSecuredPdu Header	SecuredPduHeader Enum	0..1	attr	This attribute defines the size of the header which is inserted into the SecuredIPdu. If this attribute is set to anything but noHeader, the SecuredIPdu contains the Secured I-PDU Header to indicate the length of the AuthenticIPdu. The AuthenticIPdu contains the original payload, i.e. the secured data.

Table 6.42: SecuredIPdu

[constr_9203] Existence of SecuredIPdu.payload

Imposition time: IT_SysDesc

⌈For each SecuredIPdu, the reference to PduTriggering in the role payload shall exist.⌋

[constr_9204] Existence of SecuredIPdu.secureCommunicationProps

Imposition time: IT_SysDesc

⌈For each SecuredIPdu the aggregation of SecureCommunicationProps in the role secureCommunicationProps, shall exist.⌋

Enumeration	**SecuredPduHeaderEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication
Note	Defines the header which will be inserted into the SecuredIPdu.
Aggregated by	SecuredIPdu.useSecuredPduHeader
Literal	***Description***
noHeader	No header included in the SecuredPdu. **Tags:** atp.EnumerationLiteralIndex=0
securedPdu Header08Bit	8 Bit Secured I-PDU Header included in the Secured I-PDU. **Tags:** atp.EnumerationLiteralIndex=1
securedPdu Header16Bit	16 Bit Secured I-PDU Header included in the Secured I-PDU. **Tags:** atp.EnumerationLiteralIndex=2
securedPdu Header32Bit	32 Bit Secured I-PDU Header included in the Secured I-PDU. **Tags:** atp.EnumerationLiteralIndex=3

Table 6.43: SecuredPduHeaderEnum

Class	SecureCommunicationProps			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	This meta-class contains configuration settings that are specific for an individual SecuredIPdu.			
Base	*ARObject*			
Aggregated by	SecuredIPdu.secureCommunicationProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
authDataFreshnessLength	PositiveInteger	0..1	attr	This attribute defines the length in bits of the authentic PDU data that is passed to the SWC that verifies and generates the Freshness.
authDataFreshnessStartPosition	PositiveInteger	0..1	attr	This value determines the start position in bits of the Authentic PDU that shall be passed on to the SWC that verifies and generates the Freshness. The bit counting is done according to TPS_SYST_01068.
authenticationBuildAttempts	PositiveInteger	0..1	attr	This attribute specifies the number of authentication build attempts.
authenticationRetries	PositiveInteger	0..1	attr	This attribute defines the additional number of authentication attempts that are to be carried out when the generation of the authentication information failed for a given SecuredIPdu. If zero is set than only one authentication attempt is done.
dataId	PositiveInteger	0..1	attr	This attribute defines a numerical identifier for the Secured I-PDU.
freshnessValueId	PositiveInteger	0..1	attr	This attribute defines the Id of the Freshness Value. The Freshness Value might be a normal counter or a time value.
messageLinkLength	PositiveInteger	0..1	attr	SecOC links an AuthenticIPdu and CryptographicIPdu together by repeating a specific part (Message Linker) of the AuthenticIPdu in the CryptographicIPdu. This attribute defines the length in bits of the messageLinker.
messageLinkPosition	PositiveInteger	0..1	attr	SecOC links an AuthenticIPdu and CryptographicIPdu together by repeating a specific part (Message Linker) of the AuthenticIPdu in the CryptographicIPdu. This attribute defines the startPosition in bits of the messageLinker.
secondaryFreshnessValueId	PositiveInteger	0..1	attr	This attribute defines the Id of the Secondary Freshness Value. The Secondary Freshness Value might be a normal counter or a time value. Please note that this attribute is for documentation only to allow the configuration of required freshness value manager and no upstream mapping is defined for it.
securedAreaLength	PositiveInteger	0..1	attr	This attribute defines the length in bytes of the area within the payload Pdu which will be secured.
securedAreaOffset	PositiveInteger	0..1	attr	This attribute defines the start position (offset in byte) of the area within the payload Pdu which will be secured.

Table 6.44: SecureCommunicationProps

SecureCommunicationProps.freshnessValueId does not need to be defined in case of a time-based Freshness Value. In case of a counter-based Freshness Value the freshnessValueId may be defined locally in the Ecuc or may be provided by the OEM in a System Description (this may be useful if several ECUs need to sync the freshness for a certain freshnessValueId).

[constr_9205] Existence of SecureCommunicationProps.dataId

Imposition time: IT_SysDesc

⌈For each SecureCommunicationProps, the attribute dataId shall exist.⌋

Class	**SecureCommunicationPropsSet**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication			
Note	Collection of properties used to configure SecuredIPdus. **Tags:** atp.recommendedPackage=SecureCommunicationPropsSet

Aggregated by	SecureCommunicationPropsSet.freshnessProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
freshness CounterSync Attempts	PositiveInteger	0..1	attr	This attribute defines the number of Freshness Counter re-synchronization attempts when a verification failed for a Secured I-PDU. If the value is zero, there will be no additional verification attempt to synchronize with a potentially better fitting Freshness Counter value. This attribute is only applicable if useFreshnessTimestamp is FALSE.
freshness TimestampTime PeriodFactor	PositiveInteger	0..1	attr	This attribute defines a factor that specifies the time period for the Freshness Timestamp. It holds a multiplication factor that specifies the concrete meaning of a Freshness Timestamp increment by one on basis of microseconds.
freshnessValue Length	PositiveInteger	0..1	attr	This attribute defines the complete length in bits of the Freshness Value. As long as the key doesn't change the counter shall not overflow. The length of the counter shall be determined based on the expected life time of the corresponding key and frequency of usage of the counter.
freshnessValue TxLength	PositiveInteger	0..1	attr	This attribute defines the length in bits of the Freshness Value to be included in the payload of the Secured I-PDU. This length is specific to the least significant bits of the complete Freshness Counter. If the attribute is 0 no Freshness Value is included in the Secured I-PDU.
useFreshness Timestamp	Boolean	0..1	attr	This attribute specifies whether the Freshness Value is generated through individual Freshness Counters or by a Timestamps. The value is set to TRUE when Timestamps are used.

Table 6.46: SecureCommunicationFreshnessProps

Class	**SecureCommunicationAuthenticationProps**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication

Class	**SecureCommunicationAuthenticationProps**			
Aggregated by	SecureCommunicationPropsSet.authenticationProps			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
authInfoTx Length	PositiveInteger	0..1	attr	This attribute defines the length in bits of the authentication code to be included in the payload of the authenticated Pdu.

Table 6.47: SecureCommunicationAuthenticationProps

[TPS_SYST_02281] Definition of SecuredIPdu.authDataFreshnessStartPosition ⌈SecuredIPdu.authDataFreshnessStartPosition defines the position of the most significant bit of the Freshness Value in the Pdu.⌋

[TPS_SYST_02282] Definition of SecuredIPdu.messageLinkPosition ⌈SecuredIPdu.messageLinkPosition defines the position of the most significant bit of the Message Link in the Pdu.⌋

Please note that the bit counting and bit order is defined by [TPS_SYST_01068] and [TPS_SYST_01069] and is also valid to determine the position of the authDataFreshness and messageLink.

[constr_3136] Allowed payload of SecuredIPdus

Imposition time: IT_SysDesc

⌈SecuredIPdus are allowed to reference PduTriggerings of ISignalIPdus, ContainerIPdus, DcmIPdus, MultiplexedIPdus, GeneralPurposeIPdus with category SOMEIP_SEGMENTED_IPDU and UserDefinedIPdus.⌋

Please note that it is currently not possible to refer to a SecuredIPdu in the roles MultiplexedIPdu.staticPart and MultiplexedIPdu.dynamicPart and therefore it is not possible to include SecuredIPdus in either the static part or dynamic part of a MultiplexedIPdu. In other words, a MultiplexedIPdu can be the payload of a SecuredIPdu, but conversely a SecuredIPdu cannot become a part of a MultiplexedIPdu.

[TPS_SYST_02171] Secured Area in payload Pdu

Upstream requirements: RS_SYST_00054

⌈The area within the payload Pdu that is secured is specified by the securedAreaOffset and securedAreaLength. In case that these two attributes are not configured the complete payload Pdu is secured.⌋

[constr_3399] Existence of securedAreaOffset and securedAreaLength

Imposition time: IT_SysDesc

⌈If the securedAreaOffset is defined then the securedAreaLength shall be defined as well and vice versa.⌋

[constr_3716] SecuredIPdu.dynamicRuntimeLengthHandling for dynamic length Pdus

Imposition time: IT_SysDesc

⌈If a PduTriggering is referenced from a SecuredIPdu in the role payload and the Pdu referenced by the PduTriggering in the role iPdu qualifies according to [TPS_SYST_03085] to be of dynamic length, then the SecuredIPdu shall have the attribute SecuredIPdu.dynamicRuntimeLengthHandling set to true.⌋

[constr_3717] SecuredIPdu.dynamicRuntimeLengthHandling for gateway operation with IPduMapping.pduMaxLength defined

Imposition time: IT_SysDesc

⌈If a PduTriggering refers to a SecuredIPdu in the role iPdu and that PduTriggering is used in an IPduMapping where a pduMaxLength value is defined (either in the role IPduMapping.sourceIPdu or TargetIPduRef.targetIPdu), then the SecuredIPdu shall have the attribute SecuredIPdu.dynamicRuntimeLengthHandling set to true.⌋

[constr_3718] Minimum length of SecuredIPdus

Imposition time: IT_SysDesc

⌈If a SecuredIPdu has the attribute useAsCryptographicIPdu set to false, then the length attribute of that SecuredIPdu shall be at least the sum of the payload Pdu.length and SecuredIPdu.authenticationProps.authInfoTxLength.⌋

[TPS_SYST_02152] Security profile

Upstream requirements: RS_SYST_00054

⌈The Security profile is defined by SecureCommunicationFreshnessProps.category and by SecureCommunicationAuthenticationProps.category.⌋

[constr_3324] Category of SecureCommunicationFreshnessProps and SecureCommunicationAuthenticationProps

Imposition time: IT_SysDesc

⌈SecureCommunicationFreshnessProps that is referenced by a SecuredIPdu in the role freshnessProps shall have the same category value as the SecureCommunicationAuthenticationProps that is referenced by the same SecuredIPdu in the role authenticationProps.⌋

[TPS_SYST_02153] Standardized values for the attribute category of meta-class SecureCommunicationFreshnessProps

Upstream requirements: RS_SYST_00054

⌈The following values of the attribute category of meta-class SecureCommunicationFreshnessProps are reserved by the AUTOSAR standard: PROFILE_01, PROFILE_02, PROFILE_03.⌋

[TPS_SYST_02154] Standardized values for the attribute category of meta-class SecureCommunicationAuthenticationProps

Upstream requirements: RS_SYST_00054

⌈The following values of the attribute category of meta-class SecureCommunicationAuthenticationProps are reserved by the AUTOSAR standard: PROFILE_01, PROFILE_02, PROFILE_03.⌋

[constr_3325] SecureCommunicationFreshnessProps, SecureCommunicationAuthenticationProps and CryptoServicePrimitive attribute value settings for standardized AUTOSAR security profiles

Imposition time: IT_SysDesc

⌈

Attributes	PROFILE_01	PROFILE_02	PROFILE_03
algorithmFamily	CRYPTO_ALGOFAM_AES	CRYPTO_ALGOFAM_AES	CRYPTO_ALGOFAM_AES
algorithmMode	CRYPTO_ALGOMODE_CMAC	CRYPTO_ALGOMODE_CMAC	CRYPTO_ALGOMODE_CMAC
length	128 bits	128 bits	128 bits
authInfoTxLength	24 bits	24 bits	28 bits
freshnessValueLength	Not specified	0 bits	64 bits
freshnessValueTxLength	8 bits	0 bits	4 bits

⌋

In other words if you want to define a SecuredIPdu in a particular Profile you have to reference the SecureCommunicationFreshnessProps and SecureCommunicationAuthenticationProps and the PduTriggering of this SecuredIPdu that shall reference a SecOcCryptoServiceMapping that points to CryptoServicePrimitive that contributes the authentication Algorithm and the CryptoServiceKey that contributes the length.

[constr_3339] Relation between authDataFreshnessStartPosition, authDataFreshnessLength and useAuthDataFreshness

Imposition time: IT_SysDesc

⌈If authDataFreshnessStartPosition and authDataFreshnessLength are set to a value for a SecuredIPdu then the useAuthDataFreshness shall be set as well to a value on all IPduPorts with communicationDirection = in that are referenced by a PduTriggering of the SecuredIPdu.⌋

[TPS_SYST_02189] Setting of useSecuredPduHeader attribute

Upstream requirements: RS_SYST_00054

⌈The useSecuredPduHeader shall be set to a value other than noHeader if the length of the payload Pdu is dynamic and is transmitted directly over a network which may insert padding bytes depending on the length (e.g. CANFD, Flexray).⌋

In case the SecuredIPdu is contained in a ContainerIPdu or is a TP-N-SDU, its length is correctly passed by the lower layer. In these cases the *SecuredIPduHeader* is not needed.

Please note that the dynamic-length Pdu can be an ISignalIPdu that contains a SystemSignal with dynamicLength set to true. In general it is not possible to run diagnostics on fixed-length Pdus. Therefore, there is a probability that at least a subset of DcmIPdus and UserDefinedIPdus can have dynamic length.

[constr_3406] All signals before authDataFreshnessStartPosition shall have a static length

Imposition time: IT_SysDesc

⌈In case that

- an ISignalIPdu is referenced by the SecuredIPdu with the payload reference via the PduTriggering and
- the authDataFreshnessStartPosition and authDataFreshnessLength define the area in the ISignalIPdu that is taken to verify and generate the Freshness then

all ISignals that are mapped into the ISignalIPdu in front of the configured authDataFreshnessStartPosition shall have a static length.⌋

Please note that parts of the Authentic IPdu can be used as freshness when authDataFreshnessStartPosition and authDataFreshnessLength are defined. But therefore the part of the Authentic IPdu to be used as the freshness has to be always available at same position in the Authentic IPdu.

[constr_3407] Freshness Value in Authentic IPdu is not allowed to be used in case of ContainerIPdu with a dynamic layout

Imposition time: IT_SysDesc

⌈If a ContainerIPdu that is referenced by the SecuredIPdu with the payload reference via the PduTriggering contains a dynamic layout (i.e. ContainerIPdu.headerType is set to longHeader or shortHeader) and multiple contained IPdus then each IPduPort that is referenced by the PduTriggering of the SecuredIPdu shall have the attribute useAuthDataFreshness set to false.⌋

Please note that for ContainerIPdus with a dynamic layout it cannot be ensured which contained IPdu will be put in which position (depends on various timing and trigger conditions). Therefore [constr_3407] applies.

[constr_5060] Mapping of a SecuredIPdu into a LinFrame is not allowed

Imposition time: IT_SysDesc

⌈The mapping of a SecuredIPdu into a LinFrame with a PduToFrameMapping is not allowed.⌋

In other words the usage of Pdus that are secured by SecOC is not allowed on a LIN Network.

6.3.2.1 Crypto Infrastructure for SecuredIPdu

From the cryptographic point of view, the usage of SecuredIPdu is connected to the application of two cryptographic operations, MacGenerate (for sending the SecuredIPdu) and MacVerify (for receiving the SecuredIPdu).

There are use cases for OEMs to already provide a pre-configuration of the crypto stack specifically for the handling of SecuredIPdu.

In order to support these use cases model elements in the meta-model are defined that allow for modeling a “crypto infrastructure” that facilitates the derivation of the configuration of operations MacGenerate and MacVerify in the crypto stack.

The formalization of a Pdu that is sent or received is based on the PduTriggering and its reference to an IPduPort, specifically by interpreting the attribute IPduPort.communicationDirection. The details of the approach are summarized in Figure 6.20.

[TPS_SYST_05020] Semantics of CryptoServiceMapping

Upstream requirements: RS_SYST_00054

⌈Meta-class CryptoServiceMapping represents an abstract base class for the creation of mappings in the context of cryptographic operations. Concrete sub-classes define the mapping with respect to specific cryptographic use cases, e.g. SecOC, TLS.⌋

Class	*CryptoServiceMapping* (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This meta-class represents an abstract base class for specializations of crypto service mappings.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Subclasses	SecOcCryptoServiceMapping, TlsCryptoServiceMapping			
Aggregated by	SystemMapping.cryptoServiceMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
–	–	–	–	–

Table 6.48: CryptoServiceMapping

[TPS_SYST_05021] Semantics of SecOcCryptoServiceMapping

Upstream requirements: RS_SYST_00054

⌈Meta-class SecOcCryptoServiceMapping represents the mapping functionality required for the configuration of PDU-based secure communication by means of the SecOc.

In particular, the SecOcCryptoServiceMapping associates a CryptoServicePrimitive with the applicable CryptoServiceKey.⌋

Class	SecOcCryptoServiceMapping			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This meta-class has the ability to represent a crypto service mapping for the Pdu-based communication via SecOC.			
Base	*ARObject*, *CryptoServiceMapping*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SystemMapping.cryptoServiceMapping			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
authentication	CryptoServicePrimitive	0..1	ref	This reference identifies the applicable crypto primitive for the authentication.
cryptoServiceKey	CryptoServiceKey	0..1	ref	This reference identifies the applicable crypto key.
cryptoServiceQueue	CryptoServiceQueue	0..1	ref	This reference identifies the CryptoServiceQueue the processing of this SecOcCryptoServiceMapping shall be performed in.

Table 6.49: SecOcCryptoServiceMapping

[TPS_SYST_05022] Semantics of PduTriggering.secOcCryptoMapping

Upstream requirements: RS_SYST_00054

⌈The reference PduTriggering.secOcCryptoMapping allows for modeling the relation of the usages (send, receive) of a SecuredIPdu to a given CryptoServiceMapping and thereby distinguish between the configuration of cryptographic operations MacGenerate and MacVerify.⌋

In other words, the cryptographic use case is connected to the value of attribute communicationDirection of the IPduPort that is referenced by an PduTriggering that also references a SecOcCryptoServiceMapping:

- If the value of communicationDirection is set to in then the cryptographic use case MacVerify applies.
- If the value of communicationDirection is set to out then the cryptographic use case MacGenerate applies.

[constr_1669] Existence of PduTriggering.secOcCryptoMapping

Imposition time: IT_SysDesc

⌈The reference PduTriggering.secOcCryptoMapping shall only exist if the PduTriggering also references a SecuredIPdu in the role iPdu.⌋

As the SecOcCryptoServiceMapping is referenced by a PduTriggering the SecOcCryptoServiceMapping needs to work for both the sender and the receivers of the corresponding Pdu in the context of a System of category SYSTEM_DESCRIPTION/SYSTEM_EXTRACT as well as in the context of a System of category ECU_EXTRACT.

[TPS_SYST_05023] Semantics of CryptoServicePrimitive

Upstream requirements: RS_SYST_00054

⌈Meta-class CryptoServicePrimitive allows for the description of the applicable cryptographic algorithm.⌋

Class	**CryptoServicePrimitive**			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This meta-class has the ability to represent a crypto primitive. **Tags:** atp.recommendedPackage=CryptoPrimitives			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
algorithmFamily	String	0..1	attr	This attribute represents a description of the family (e.g. AES) of crypto algorithm implemented by the crypto primitive.
algorithmMode	String	0..1	attr	This attribute represents a description of the mode of the crypto algorithm implemented by the crypto primitive.
algorithm Secondary Family	String	0..1	attr	This attribute represents a further description of the secondary family of crypto algorithm implemented by the crypto primitive. The secondary family is needed for the specification of the hash algorithm for a signature check, e.g. using RSA.

Table 6.50: CryptoServicePrimitive

[TPS_SYST_05024] Semantics of CryptoServiceKey

Upstream requirements: RS_SYST_00054

⌈Meta-class CryptoServiceKey allows for the description of the applicable cryptographic key. The ability to aggregate a ValueSpecification in the role developmentValue shall be used to distribute development keys to suppliers such that crypto functionality can be adequately verified during development.⌋

[constr_5334] Supported values for CryptoServiceKey.length

Imposition time: IT_SysDesc

⌈The values defined for CryptoServiceKey.length shall be multiple of 8.⌋

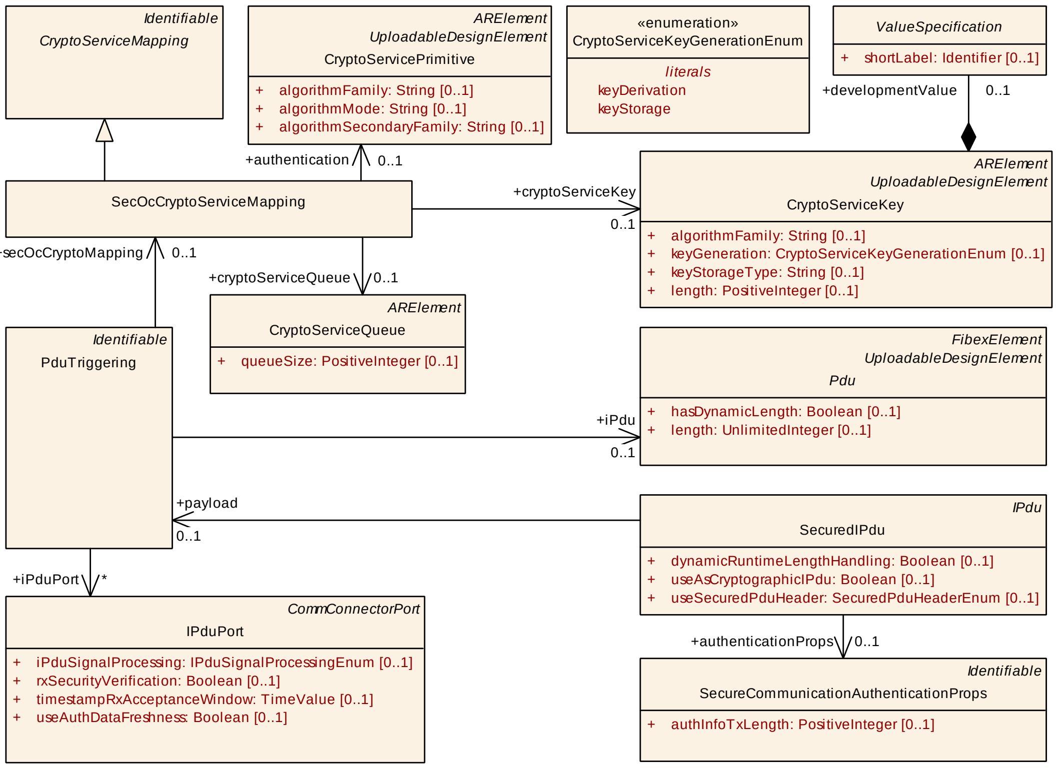

Figure 6.20: Modeling of crypto infrastructure for SecuredIPdu

Please note that the developmentValue most likely will be used in the form of a TextValueSpecification. However, the aggregation has still be modeled by means of using the abstract base class ValueSpecification to gain some headroom for future extension.

Class	**CryptoServiceKey**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication

- **CRYPTO_ALGOMODE_GCM**: Blockmode - Galois/Counter Mode
- **CRYPTO_ALGOMODE_XTS**: XOR-encryption-based tweaked-codebook mode with ciphertext stealing
- **CRYPTO_ALGOMODE_RSAES_OAEP**: RSA Optimal Asymmetric Encryption Padding
- **CRYPTO_ALGOMODE_RSAES_PKCS1_v1_5**: RSA encryption/decryption with PKCS#1 v1.5 padding
- **CRYPTO_ALGOMODE_RSASSA_PSS**: RSA Probabilistic Signature
- **CRYPTO_ALGOMODE_RSASSA_PKCS1_v1_5**: RSA signature with PKCS#1 v1.5
- **CRYPTO_ALGOMODE_8ROUNDS**: 8 rounds (e.g. ChaCha8)
- **CRYPTO_ALGOMODE_12ROUNDS**: 12 rounds (e.g. ChaCha12)
- **CRYPTO_ALGOMODE_20ROUNDS**: 20 rounds (e.g. ChaCha20)
- **CRYPTO_ALGOMODE_HMAC**: Hashed-based MAC
- **CRYPTO_ALGOMODE_CMAC**: Cipher-based MAC

- **CRYPTO_ALGOMODE_GMAC**: Galois MAC
- **CRYPTO_ALGOMODE_CTRDRBG**: Counter-based Deterministic Random Bit Generator
- **CRYPTO_ALGOMODE_SIPHASH_2_4**: Siphash-2-4
- **CRYPTO_ALGOMODE_SIPHASH_4_8**: Siphash-4-8
- **CRYPTO_ALGOMODE_AESKEYWRAP**: AES Key Wrap (RFC 3394)

⌋

Please note that it is positively supported to define custom values for attributes CryptoServicePrimitive.algorithmFamily and CryptoServicePrimitive.algorithmMode provided that the custom values are guaranteed to not clash with future extension of the AUTOSAR standard. For example, this could be achieved by using a prefix or suffix that is specific to the organization that defines the custom value.

[TPS_SYST_05028] Semantics of CryptoServiceKey.keyStorageType

Upstream requirements: RS_SYST_00054

⌈Attribute CryptoServiceKey.keyStorageType describes where the actual key shall be stored on the ECU. This attribute has been deliberately modeled as a String to allow future (and custom) extensions of the range of possible values.

AUTOSAR reserves the following values for this attribute:

- **SHE**
- **RAM**
- **HSM**
- **NVM**

⌋

Please note that custom values for attribute CryptoServiceKey.keyStorageType are supported as long as the actual values are defined in a way such that a possible clash with a later standardization by AUTOSAR becomes impossible.

The best way to achieve this is to use the company name (e.g. as a prefix) within the custom value of CryptoServiceKey.keyStorageType.

Class	**CryptoServiceQueue**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication
Note	This meta-class has the ability to represent a crypto queue. **Tags:** atp.recommendedPackage=CryptoServiceQueues

Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
payload	PduTriggering	0..1	ref	References the ISignalIPdu that represents the SDG (Safety Data Group) that contains both the payload (signals) and the E2E protection data of the protected J1939 message. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=payload.pduTriggering, payload.variationPoint.shortLabel atp.Status=draft vh.latestBindingTime=postBuild
srvt	TimeValue	0..1	attr	Maximum time between SHM (Safety Header Message) and SDM (Safety Data Message) of one SDG (Safety Data Group) **Tags:** atp.Status=draft

Table 6.54: J1939ProtectedIPdu

The following Figure 6.22 shows in an example how a J1939ProtectedIPdu is modeled. The J1939ProtectedIPdu is transmitted on the network and is therefore mapped into a CanFrame. Both, the J1939ProtectedIPdu and the J1939ProtectedIPdu.payload ISignalIPdu have a PduTriggering on the same CAN PhysicalChannel. The payload ISignalIPdu contains an ISignalGroup with aggregated EndToEndTransformationISignalProps.

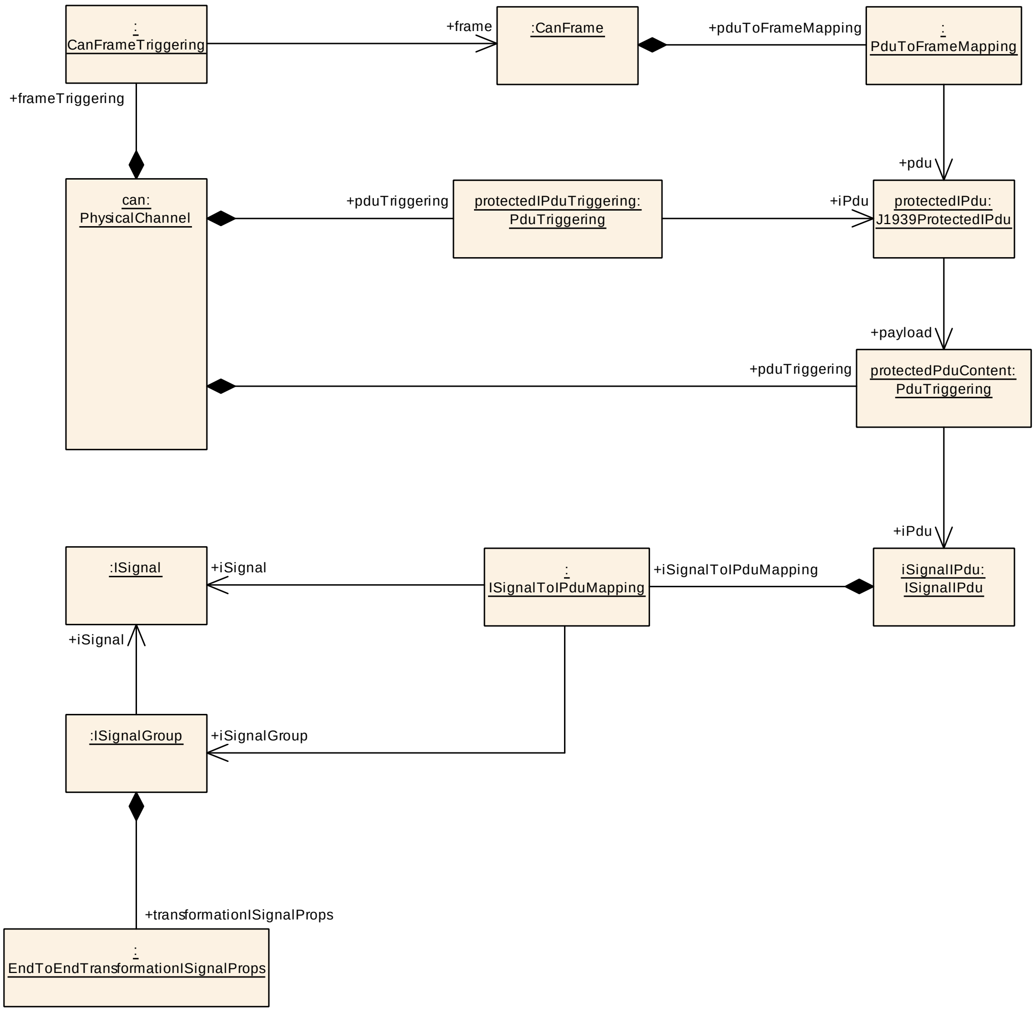

Figure 6.22: Example for modeling of J1939ProtectedIPdu

6.3.4 EndToEndProtection for ISignalGroups

Caveat: Since the E2E wrapper approach involves technologies that are not subjected to the AUTOSAR standard and since it is superseded by the superior E2E transformer approach (which is fully standardized by AUTOSAR), support for the E2E wrapper approach will eventually be discontinued by AUTOSAR. Thus those AUTOSAR artifacts (e.g., specification items, meta classes) are to be considered as obsolete according to [TPS_STDT_00064] and will be removed from AUTOSAR with R25-11. New projects (without legacy constraints due to carry-over parts) shall use the fully standardized E2E transformer approach.

[TPS_SYST_01070] E2E Protection of ISignalGroups
Status: OBSOLETE
Upstream requirements: RS_SYST_00028

⌈It is possible to protect the inter-ECU data exchange of safety-related ISignalGroups which are mapped into ISignalIPdus using protection mechanisms provided by E2E Library.⌋

[TPS_SYST_01071] E2E Protection of several ISignalGroups in one ISignalIPdu
Status: OBSOLETE
Upstream requirements: RS_SYST_00028

⌈It is possible to protect several ISignalGroups in one ISignalIPdu using several EndToEndProtectionISignalIPdu elements.⌋

The EndToEndProtectionISignalIPdu element refers to the ISignalGroup that is to be protected and to the ISignalIPdu that transmits the protected ISignalGroup. The dataOffset in the EndToEndProtectionISignalIPdu element defines the starting position of the Array representation of the ISignalGroup.

The information how the referenced ISignalGroup shall be protected (through which E2E Profile and with which E2E settings) is defined in the EndToEndDescription element.

[TPS_SYST_01072] Offset attributes of EndToEndDescription
Status: OBSOLETE
Upstream requirements: RS_SYST_00028

⌈All offset attributes of EndToEndDescription are relative to the dataOffset with respect to the ISignalIPdu (absolute position of the CRC = dataOffset + crcOffset).⌋

For more details, see End to End Library [22].

[TPS_SYST_01073] E2E Protection via COM Callouts
Status: OBSOLETE
Upstream requirements: RS_SYST_00028

⌈If the E2E Protection is done via COM Callouts then the EndToEndProtectionISignalIPdu shall be defined.⌋

[TPS_SYST_01074] E2E Protection in the E2E Wrapper
Status: OBSOLETE
Upstream requirements: RS_SYST_00028

⌈If the E2E Protection is done in the E2E Wrapper then both EndToEndProtectionISignalIPdu and EndToEndProtectionVariablePrototype shall be defined.

Caveat: The E2E transformer approach is the standardized AUTOSAR way.⌋

For more details, see Software Component Template specification [4].

[constr_1002] End-to-end protection does not support n:1 communication

Status: OBSOLETE
Imposition time: IT_SysDesc

⌈As the n:1 communication scenario implies that probably not all senders use the same dataId this scenario is explicitly not supported.⌋

⌈For each EndToEndProtectionISignalIPdu, the attribute dataOffset shall exist.⌋

Class	**EndToEndDescription**			
Package	M2::AUTOSARTemplates::SWComponentTemplate::EndToEndProtection			
Note	This meta-class contains information about end-to-end protection. The set of applicable attributes depends on the actual value of the category attribute of EndToEndProtection. **Tags:** atp.Status=obsolete			
Base	*ARObject*			
Aggregated by	EndToEndProtection.endToEndProfile			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
category	NameToken	0..1	attr	The category represents the identification of the concrete E2E profile. The applicable values are specified in a semantic constraint and determine the applicable attributes of EndToEndDescription. **Tags:** atp.Status=obsolete xml.sequenceOffset=-100
counterOffset	PositiveInteger	0..1	attr	Bit offset of Counter from the beginning of the Array representation of the Signal Group/VariableDataPrototype (MSB order, bit numbering: bit 0 is the least important). The offset shall be a multiplicity of 4 and it should be 8 whenever possible. For example, offset 8 means that the counter will take the low nibble of the byte 1, i.e. bits 8 .. 11. If counterOffset is not present the value is defined by the selected profile. **Tags:** atp.Status=obsolete xml.sequenceOffset=-50

▽

△

Class	**EndToEndDescription**			
crcOffset	PositiveInteger	0..1	attr	Bit offset of CRC from the beginning of the Array representation of the Signal Group/VariableDataPrototype (MSB order, bit numbering: bit 0 is the least important). The offset shall be a multiplicity of 8 and it should be 0 whenever possible. For example, offset 8 means that the CRC will take the byte 1, i.e. bits 8..15. If crcOffset is not present the value is defined by the selected profile. **Tags:** atp.Status=obsolete xml.sequenceOffset=-60
dataId (ordered)	PositiveInteger	*	attr	This represents a unique numerical identifier. Note: ID is used for protection against masquerading. The details concerning the maximum number of values (this information is specific for each E2E profile) applicable for this attribute are controlled by a semantic constraint that depends on the category of the EndToEnd Protection. **Tags:** atp.Status=obsolete xml.sequenceOffset=-90
dataIdMode	PositiveInteger	0..1	attr	There are three inclusion modes how the implicit two-byte Data ID is included in the one-byte CRC: • dataIDMode = 0: Two bytes are included in the CRC (double ID configuration) This is used in variant 1A. • dataIDMode = 1: One of the two bytes byte is included, alternating high and low byte, depending on parity of the counter (alternating ID configuration). For even counter low byte is included; For odd counters the high byte is included. This is used in variant 1B. • dataIDMode = 2: Only low byte is included, high byte is never used. This is applicable if the IDs in a particular system are 8 bits. • dataIdMode = 3: The low byte is included in the implicit CRC calculation, the low nibble of the high byte is transmitted along with the data (i.e. it is explicitly included), the high nibble of the high byte is not used. This is applicable for the IDs up to 12 bits. **Tags:** atp.Status=obsolete xml.sequenceOffset=-85
dataIdNibble Offset	PositiveInteger	0..1	attr	Bit offset of the low nibble of the high byte of Data ID. The applicability of this attribute is controlled by [constr_1261]. **Tags:** atp.Status=obsolete xml.sequenceOffset=-25
dataLength	PositiveInteger	0..1	attr	This attribute represents the length of the Array representation of the Signal Group/VariableDataPrototype including CRC and Counter in bits. **Tags:** atp.Status=obsolete xml.sequenceOffset=-80

▽

△

Class	EndToEndDescription			
maxDelta CounterInit	PositiveInteger	0..1	attr	Initial maximum allowed gap between two counter values of two consecutively received valid Data, i.e. how many subsequent lost data is accepted. For example, if the receiver gets Data with counter 1 and MaxDeltaCounter Init is 1, then at the next reception the receiver can accept Counters with values 2 and 3, but not 4. Note that if the receiver does not receive new Data at a consecutive read, then the receiver increments the tolerance by 1. **Tags:** atp.Status=obsolete xml.sequenceOffset=-70
maxNoNewOr RepeatedData	PositiveInteger	0..1	attr	The maximum amount of missing or repeated Data which the receiver does not expect to exceed under normal communication conditions. **Tags:** atp.Status=obsolete xml.sequenceOffset=-40
syncCounterInit	PositiveInteger	0..1	attr	Number of Data required for validating the consistency of the counter that shall be received with a valid counter (i.e. counter within the allowed lock-in range) after the detection of an unexpected behavior of a received counter. **Tags:** atp.Status=obsolete xml.sequenceOffset=-30

Table 6.58: EndToEndDescription

[constr_1001] Value of `dataId` shall be unique

Status: OBSOLETE
Imposition time: `IT_SysDesc`

⌈The value of the `dataId` shall be unique within the scope of the `System`.⌋

The `maxDeltaCounterInit`, `maxNoNewOrRepeatedData` and `syncCounterInit` values can also be specified in the `ReceiverComSpec`. This allows the definition of receiver specific values. Values for `maxDeltaCounterInit`, `maxNoNewOrRepeatedData` and `syncCounterInit` that are defined in the `ReceiverComSpec` override the possible values in the `EndToEndDescription` class.

Caveat: Since the definition of those values is intended for the E2E wrapper approach, those definitions are to be considered as obsolete according to [TPS_STDT_00064] and will be removed from AUTOSAR with R25-11.

More details about those values can be found in the Software Component Template specification [4].

The supported E2E profiles (possible values of category in EndToEndDescription) are described in the Software Component Template [4] and the End to End Library [22].

6.3.5 GeneralPurposeConnection

In some cases it is important to describe a relation between different PduTriggerings that are defined on the same PhysicalChannel, e.g. to create a link between a Rx-Pdu and a Tx-Pdu. The GeneralPurposeConnection meta-class is able to reference a number of PduTriggerings and thereby to set the referenced PduTriggerings into a relationship that is defined by the GeneralPurposeConnection.

[TPS_SYST_02170] category of the GeneralPurposeConnection ⌈The category of the GeneralPurposeConnection is used to define the purpose of the relationship between the referenced PduTriggerings.⌋

Imposition time: IT_SysDesc

⌈The following values of the attribute category of meta-class GeneralPurposeConnection are reserved by the AUTOSAR standard:

- XcpChannel

⌋

The XcpChannel creates a link between one Tx-Pdu and one Rx-Pdu that are used for request/response from one master.

[constr_3385] XcpChannel is allowed to reference exactly two PduTriggerings

Imposition time: IT_SysDesc

⌈In case that the category of meta-class GeneralPurposeConnection is set to the value *XcpChannel* the GeneralPurposeConnection is allowed to reference exactly two PduTriggerings in the role pduTriggering.⌋

[constr_3386] XcpChannel is only allowed to reference PduTriggerings of GeneralPurposeIPdus with category XCP

Imposition time: IT_SysDesc

⌈In case that the category of meta-class GeneralPurposeConnection is set to the value *XcpChannel* the GeneralPurposeConnection is allowed to reference PduTriggerings of GeneralPurposeIPdus with category XCP.⌋

6.4 IPdu Timing

AUTOSAR COM allows configuring statically two different transmission modes for each IPdu (True and False). TransmissionModeDeclaration uses a transmission mode selector, calculated from a number of individual TransmissionModeConditions or ModeDrivenTransmissionModeConditions to decide which of the two modes is selected. It is possible to switch between the transmission modes during runtime.

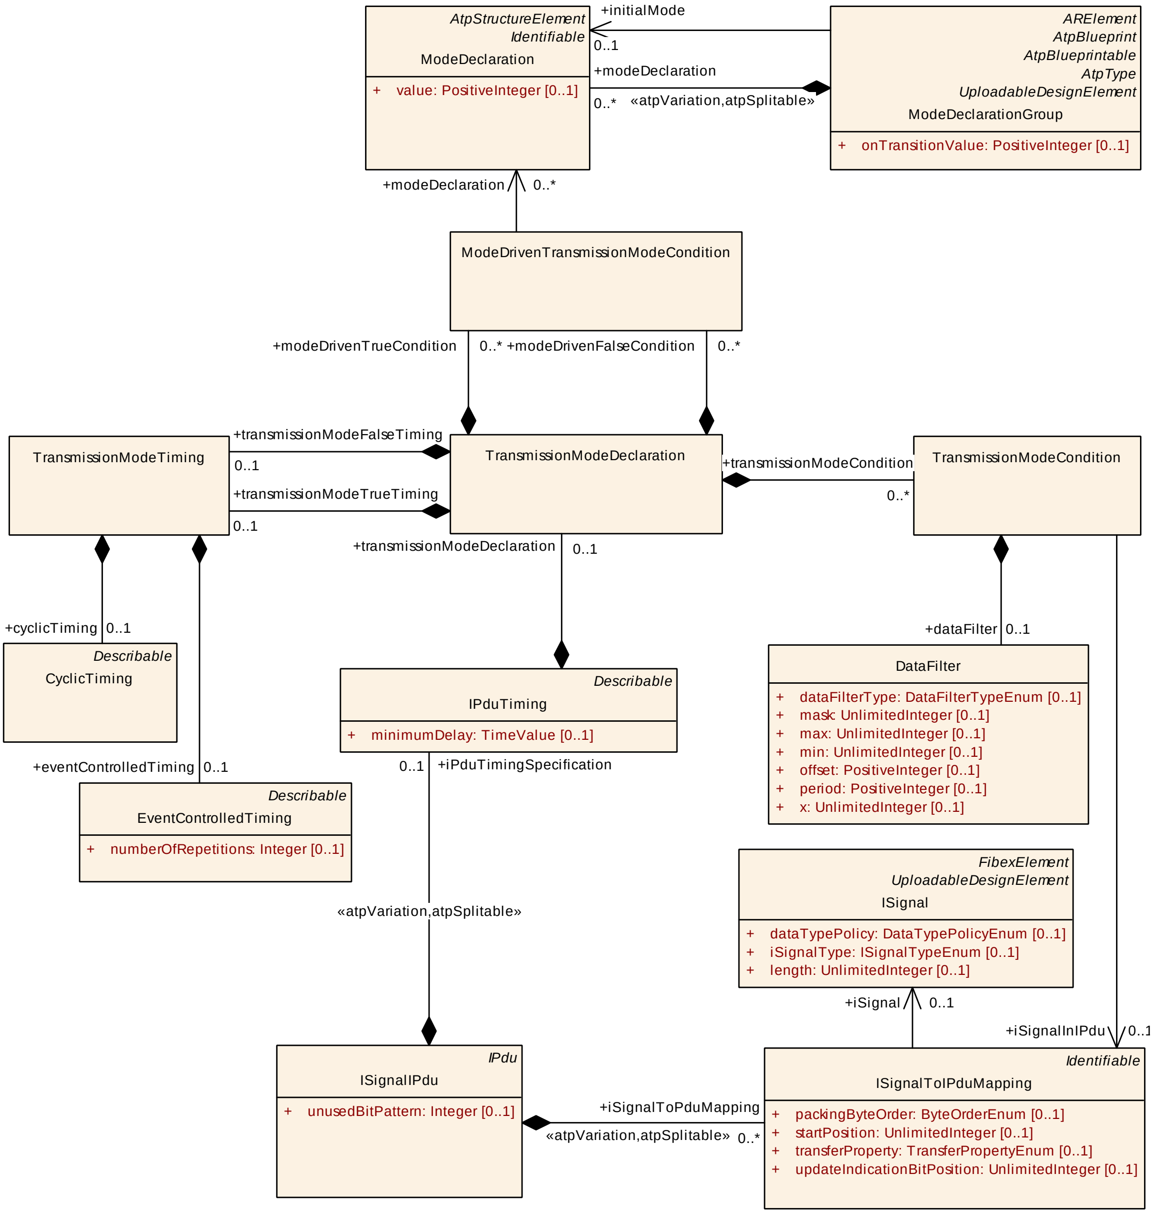

Figure 6.25: IPdu Timing

[TPS_SYST_01075] Signal content evaluation via TransmissionModeCondition

Upstream requirements: RS_SYST_00037

⌈The signal content can be evaluated as the transmission mode selector via the TransmissionModeConditions.⌋

[TPS_SYST_01076] Mode evaluation via modeDrivenTrueCondition or modeDrivenFalseCondition

Upstream requirements: RS_SYST_00037

⌈Mode conditions can be evaluated as the transmission mode selector via the modeDrivenTrueConditions or modeDrivenFalseConditions.⌋

[constr_3045] Signal content evaluation vs. Mode evaluation

Imposition time: IT_SysDesc

⌈The mode evaluation and the signal content evaluation shall not be used in the same IPdu. A mix of these two types is not allowed.⌋

To use the signal content evaluation a TransmissionModeCondition can be attached to each signal within an IPdu. Each TransmissionModeCondition contains a reference to a signal and to an assigned filter. The filter condition is used for the selection of the transmission mode. If at least one condition in the signal content evaluation is true, Transmission Mode "TRUE" shall be used for this IPdu. In all other cases, the Transmission Mode "FALSE" shall be used. More details can be found in the COM Specification [21].

[constr_3046] Consistency of TransmissionModeCondition.iSignalInIPdu

Imposition time: IT_SysDesc

⌈The ISignalToIPduMapping referenced by the TransmissionModeCondition in the role iSignalInIPdu shall belong to the same ISignalIPdu as the TransmissionModeCondition.⌋

In the mode driven evaluation ModeDeclarations are evaluated. The transmissionModeFalseTiming is activated if all defined modeDrivenFalseConditions evaluate to true and the transmissionModeTrueTiming is activated if all defined modeDrivenTrueConditions evaluate to true. Each condition that is defined by ModeDrivenTransmissionModeCondition evaluates to true if one of the referenced ModeDeclarations is active.

The TransmissionModeDeclaration element aggregates the TransmissionModeTiming in two different roles: transmissionModeTrueTiming and transmissionModeFalseTiming. The available COM Transmission Mode Timings can be described by the CyclicTiming and EventControlledTiming elements (see [TPS_SYST_01077]) that are aggregated by the TransmissionModeTiming class.

[TPS_SYST_01077] Mapping of Com Transmission Modes to System Template elements

Upstream requirements: RS_SYST_00037

⌈

COM Transmission Modes	*Description*	*realization in System Template*
Periodic	Transmissions occur indefinitely with a fixed time period between them	CyclicTiming
Direct/n-times	Event driven transmission with n-1 repetitions	EventControlledTiming
Mixed	Periodic transmission with direct/n-times transmissions in between	EventControlledTiming and CyclicTiming
None	No transmission	no timing assigned

⌋

Class	**TransmissionModeDeclaration**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication::Timing			
Note	AUTOSAR COM provides the possibility to define two different TRANSMISSION MODES (True and False) for each I-PDU. As TransmissionMode selector the signal content can be evaluated via transmissionModeCondition (implemented directly in the COM module) or mode conditions can be defined with the modeDrivenTrue Condition or modeDrivenFalseCondition (evaluated by BswM and invoking Com_SwitchIpduTxMode COM API). If modeDrivenTrueCondition and modeDrivenFalseCondition are defined they shall never evaluate to true both at the same time. The mixing of Transmission Mode Switch via API and signal value is not allowed.

⌈For each AbsoluteTolerance, the attribute absolute shall exist.⌋

6.4.4 Configuration of a trigger for COM_TriggerIPduSend API call

In the AUTOSAR BswM module a BswMAction with BswMTriggerIPduSend may be defined. The COM API Com_TriggerIPDUSend is called when this action is configured. By the call of Com_TriggerIPDUSend an IPdu with a given ID is triggered for transmission.

With such a configuration a single transmission of an IPdu can be configured that is independent of the configured COM transmission modes, e.g. in case of a vehicle mode change.

In a System Description the usage of the Com_TriggerIPDUSend API is defined with the TriggerIPduSendCondition that is aggregated by the PduTriggering in the role triggerIPduSendCondition. The TriggerIPduSendCondition defines the trigger for the Com_TriggerIPDUSend API call.

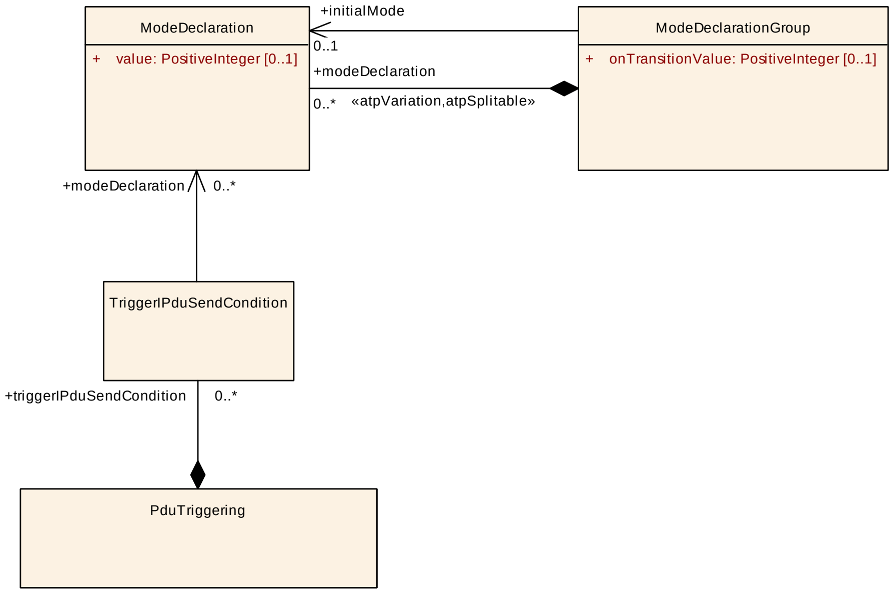

Figure 6.29: TriggerIPduSendCondition

Class	**TriggerIPduSendCondition**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication::Timing			
Note	The condition defined by this class evaluates to true if one of the referenced modeDeclarations (OR associated) is active. The condition is used to define when the Pdu is triggered with the Com_Trigger IPDUSend API call.

Please note that OR Conditions defined by the TriggerIPduSendCondition.modeDeclaration are evaluated first. The AND Conditions defined by PduTriggering.triggerIPduSendConditions are evaluated after the OR Conditions.

6.5 I-Pdu Multiplexer

Multiplexing is used to transport varying Com IPdus at the same position in a single multiplexed IPdu. A multiplexed IPdu consists of a dynamic part, a selector field and an optional static part. According to the value of the selector field the dynamic part can have a different layout.

[TPS_SYST_01078] Dynamic Part of a MultiplexedIPdu ⌈For each alternative of a MultiplexedIPdu there is exactly one Com IPdu that is transmitted in the dynamic part.⌋

[TPS_SYST_01079] Static Part of a MultiplexedIPdu ⌈The static part of a MultiplexedIPdu is the same regardless of the selector field and consists of exactly one Com IPdu.⌋

The MultiplexedIPdu element contains attributes that describe the position and the length of a selector within an IPdu. A selector is a bitfield of certain length, by the value of which the corresponding data region of the dynamic part shall be interpreted dynamically, i.e. at run-time.

[constr_3007] selectorFieldCodes for dynamic part alternatives

Imposition time: IT_SysDesc

⌈The selectorFieldCodes for the dynamic part alternatives within one MultiplexedIPdu shall differ from each other.⌋

[constr_3097] Overlapping of segments of one MultiplexedIPdu is not allowed

Imposition time: IT_SysDesc

⌈The segments defined by the SegmentPosition elements of one and the same MultiplexedIPdu - aggregated via StaticPart and DynamicPart - shall not overlap.⌋

[constr_3098] Defined segments of one MultiplexedIPdu shall not exceed the length of the MultiplexedIPdu

Imposition time: IT_SysDesc

⌈The segments defined by the SegmentPosition elements of one and the same MultiplexedIPdu - aggregated via StaticPart and DynamicPart - shall not exceed the length of the MultiplexedIPdu.⌋

[constr_3099] Defined segments in a DynamicPart shall not exceed the length of any DynamicPartAlternative.iPdu

Imposition time: IT_SysDesc

⌈The segments defined by the SegmentPosition elements aggregated in the DynamicPart of a MultiplexedIPdu shall not exceed the length of any DynamicPartAlternative.iPdu.⌋

[constr_3100] Defined segments in a StaticPart shall not exceed the length of the StaticPart.iPdu

Imposition time: IT_SysDesc

⌈The segments defined by the SegmentPosition elements aggregated in the StaticPart of a MultiplexedIPdu shall not exceed the length of the StaticPart.iPdu⌋

[constr_3101] Signal representation of selector field for DynamicPartAlternative

Imposition time: IT_SysDesc

⌈Every ISignalIPdu that is referenced by the DynamicPartAlternative shall contain an ISignal that represents the selector field. The selector field signal shall be located at the position that is described by the selectorFieldLength and selectorFieldStartPosition.⌋

[constr_5254] Value range of MultiplexedIPdu.selectorFieldLength

Imposition time: IT_SysDesc

⌈The value of MultiplexedIPdu.selectorFieldLength shall be in the range of 1..16 Bits.⌋

It is assumed by the IPduM that the value of the ISignal representing the selector field value matches the value defined in DynamicPartAlternative.selectorFieldCode. The IPduM does not set or modify the selector field value. Therefore it is essential that the System Description is defined in a consistent way in order to get valid selector field value configurations.

There are two approaches how the selector field value is configured:

- static initialization of the ISignal representing the selector field value.
- giving applications the possibility to write the selector field value.

If the selector field value is initialized using the ISignal representing the selector field value then the consistency is defined in [TPS_SYST_02351]. In this case there is no change to the value of the ISignal representing the selector field value during runtime. Each DynamicPartAlternative has a corresponding IPdu with a correctly defined selector field value. Regardless which DynamicPartAlternative is triggered by COM, it always has the correct selector field value.

[TPS_SYST_02351] Selector field signal initial values in case no application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is neither
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal nor
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping,

then this ISignal representing the selector field shall have an initValue defined which corresponds to the DynamicPartAlternative.selectorFieldCode of the respective dynamic part alternative ISignalIPdu.⌋

If the application shall be able to write the selector field value then the following specification items apply: [TPS_SYST_02352], [constr_5232], [TPS_SYST_02353], [TPS_SYST_02355], [TPS_SYST_02356], [constr_5233].

One possible use-case for the application to be able to write the selector field value is to use the applications write access as the trigger to send out one specific DynamicPartAlternative, exactly that DynamicPartAlternative which matches the written selector field value. In order to achieve this functionality the COM module needs to be configured according to the rules defined below.

The IPduM on sender side gets transmission requests from COM (for the case of application writing the selector field value: the case of trigger transmit is excluded in [TPS_SYST_02353]).

[TPS_SYST_02355] defines that only the valid DynamicPartAlternative is actually triggered for transmission by the COM module, and thus is made available to the IPduM.

From the perspective of the IPduM there is not difference whether the selector field value has been defined by initializing the COM-Signal or whether the application has written the selector field value and the COM module has filtered the proper DynamicPartAlternative to be sent to the IPduM.

[TPS_SYST_02352] Triggering in case of application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping,

then this ISignal representing the selector field shall be the only ISignal that is mapped into the dynamic part alternative ISignalIPdu with a transferProperty set to an arbitrary value.⌋

[constr_5232] Triggering in case of application writing the selector field signal

Imposition time: IT_SysDesc

⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then any ISignal other than the ISignal representing the selector field shall be mapped into that dynamic part alternative ISignalIPdu using the transferProperty set to pending.⌋

In other words, if the selector field signal is written by the application software, then the selector field ISignal may be the only ISignal which triggers the dynamic part alternative ISignalIPdu. No triggering of a dynamic part alternative ISignalIPdu may be a use case as well, in such cases a cyclic transmission would still be possible.

[TPS_SYST_02353] No support for trigger transmit in case of application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and

- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then the dynamic part alternative ISignalIPdu, where the ISignal representing the selector field is mapped to, shall not be used in a trigger transmit COM stack configuration.⌋

[TPS_SYST_02354] No support for Just-In-Time update of dynamic parts in case of application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then the IpduMJitUpdate configuration parameter of the IpduMTxDynamicPart corresponding to the ISignalIPdu shall be configured to false during ECU Configuration.⌋

In other words, if the selector field signal is written by the application software, then the dynamic part alternative ISignalIPdu shall only be triggered by the application layer, no trigger transmit support allowed.

[TPS_SYST_02355] TransmissionModeDeclaration in case of application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or

  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then the dynamic part alternative ISignalIPdu, where the ISignal representing the selector field is mapped to, shall have an ISignalIPdu.iPduTimingSpecification with a TransmissionModeDeclaration where the TransmissionModeDeclaration.transmissionModeCondition defines a TransmissionModeCondition with

- TransmissionModeCondition.iSignalInIPdu refers to the ISignalToIPduMapping which maps the ISignal representing the selector field
- DataFilter.dataFilterType = maskedNewEqualsX,
- DataFilter.mask is set to $(2^{<selectorfield\_bitsize>})$ - 1, where <selectorfield_bitsize> is the size of the selector field signal in bits, i.e. ISignal.length of the ISignal representing the selector field,
- DataFilter.x corresponds to the DynamicPartAlternative.selectorFieldCode of the respective dynamic part alternative ISignalIPdu,
- TransmissionModeDeclaration.transmissionModeFalseTiming shall not be defined.

⌋

[TPS_SYST_02356] Only one TransmissionModeCondition in case of application writing the selector field signal ⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then the dynamic part alternative ISignalIPdu, where the ISignal representing the selector field is mapped to, shall have an ISignalIPdu.iPduTimingSpecification with a TransmissionModeDeclaration where there is only one TransmissionModeCondition defined, as specified in [TPS_SYST_02355].⌋

In other words, when the application software writes the selector field signal only that dynamic part alternative ISignalIPdu with the matching selectorFieldCode is actually available for sending.

[constr_5233] Usage of invalidValue in case of application writing the selector field signal

Imposition time: IT_SysDesc

⌈If

- the ISignal representing the selector field is referenced by an ISignalTriggering and that ISignalTriggering refers to an ISignalPort where the communicationDirection is set to out and
- the ISignal representing the selector field is referring to a SystemSignal and that SystemSignal is either
  - referenced by a SenderReceiverToSignalMapping in the role systemSignal or
  - part of a SystemSignalGroup that in turn is referenced by a SenderReceiverToSignalGroupMapping

then

- the ISignal representing the selector field shall either
  - define no invalid value (ISignal.networkRepresentationProps.invalidValue) or
  - the invalidValue defined shall be different than any of the defined selector field values for that MultiplexedIPdu.

⌋

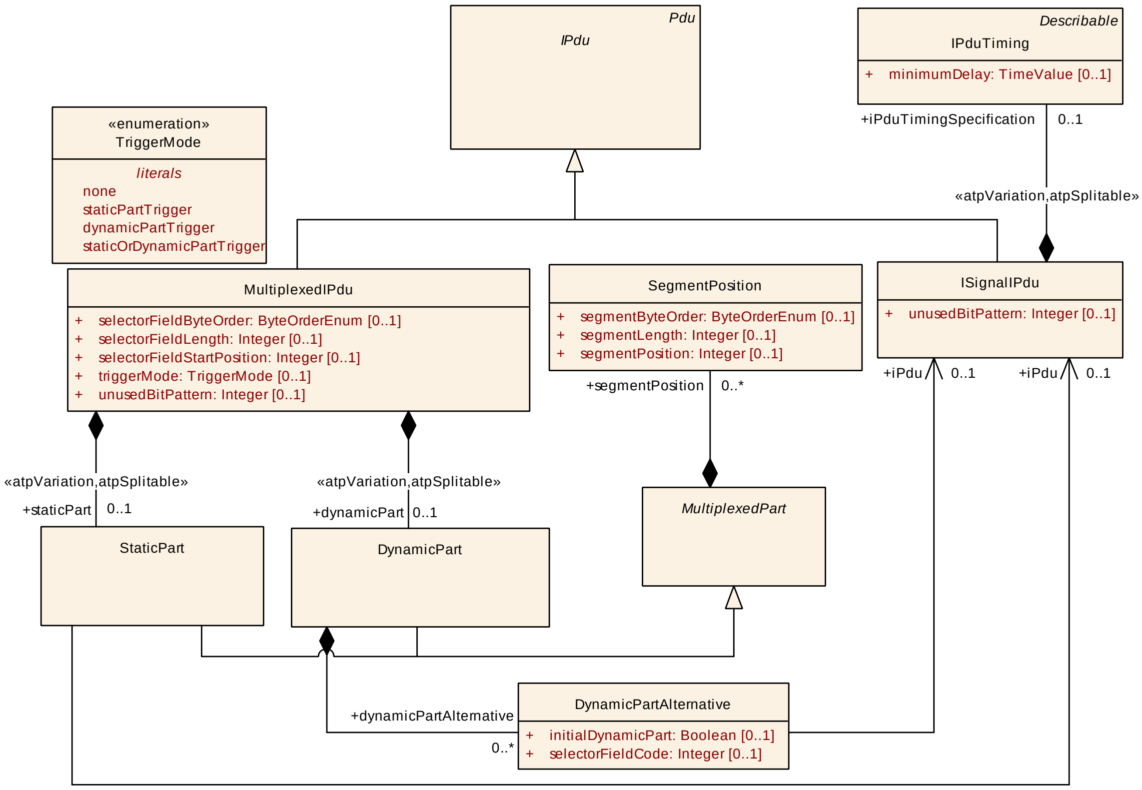

Figure 6.30: I-Pdu Multiplexer (FibexCore: IPDUMultiplexerOverview)

Enumeration	TriggerMode
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::FibexCore::CoreCommunication

dynamicPart	DynamicPart	0..1	aggr	According to the value of the selector field some parts of the IPdu have a different layout. In a complete System Description a MultiplexedIPdu shall contain a Dynamic Part. The following use cases support the multiplicity to be 0..1: • If a MultiplexedIPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedIPdu doesn't need to be described in the System Extract/ Ecu Extract. • If a MultiplexedIPdu is received by an ECU which is only interested in the static part of the MultiplexedIPdu then the dynamicPart does not need to be described in the System Extract/Ecu Extract. atpVariation: Content of a multiplexed PDU can vary. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=dynamicPart, dynamicPart.variationPoint.shortLabel vh.latestBindingTime=postBuild

▽

△

Class	**MultiplexedIPdu**			
selectorField ByteOrder	ByteOrderEnum	0..1	attr	This attribute defines the order of the bytes of the selector Field and the packing into the MultiplexedIPdu. Please consider that [constr_3247] and [constr_3223] are restricting the usage of this attribute. In a complete System Description this attribute is mandatory. If a MultiplexedPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedPdu doesn't need to be described in the System Extract/Ecu Extract. To support this use case the multiplicity is set to 0..1.
selectorField Length	Integer	0..1	attr	The size in bits of the selector field shall be configurable in a range of 1-16 bits. In a complete System Description this attribute is mandatory. If a MultiplexedPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedPdu doesn't need to be described in the System Extract/Ecu Extract. To support this use case the multiplicity is set to 0..1.
selectorField StartPosition	Integer	0..1	attr	This parameter is necessary to describe the position of the selector field within the IPdu. Note that the absolute position of the selectorField in the MultiplexedIPdu is determined by the definition of the selectorFieldByteOrder attribute of the Multiplexed Pdu. If Big Endian is specified, the start position indicates the bit position of the most significant bit in the IPdu. If Little Endian is specified, the start position indicates the bit position of the least significant bit in the IPdu. In AUTOSAR the bit counting is always set to "sawtooth" and the bit order is set to "Decreasing". The bit counting in byte 0 starts with bit 0 (least significant bit). The most significant bit in byte 0 is bit 7. In a complete System Description this attribute is mandatory. If a MultiplexedPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedPdu doesn't need to be described in the System Extract/Ecu Extract. To support this use case the multiplicity is set to 0..1.
staticPart	StaticPart	0..1	aggr	The static part of the multiplexed IPdu is the same regardless of the selector field. The static part is optional. atpVariation: Content of a multiplexed PDU can vary. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=staticPart, staticPart.variationPoint.short Label vh.latestBindingTime=postBuild
triggerMode	TriggerMode	0..1	attr	IPduM can be configured to send a transmission request for the new multiplexed IPdu to the PDU-Router because of the trigger conditions/ modes that are described in the TriggerMode enumeration. In a complete System Description this attribute is mandatory. If a MultiplexedPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedPdu doesn't need to be described in the System Extract/Ecu Extract. To support this use case the multiplicity is set to 0..1.

▽

△

Class	MultiplexedIPdu			
unusedBit Pattern	Integer	0..1	attr	AUTOSAR COM and AUTOSAR IPDUM are filling not used areas of an IPdu with this bit-pattern. This attribute is mandatory to avoid undefined behavior. This byte-pattern will be repeated throughout the IPdu. In a complete System Description this attribute is mandatory. If a MultiplexedPdu is received by a Pdu Gateway and is not delivered to the IPduM but routed directly to a bus interface then the content of the MulitplexedPdu doesn't need to be described in the System Extract/Ecu Extract. To support this use case the multiplicity is set to 0..1.

Figure 6.31 shows an example of an IPdu Multiplexer. The static part of the multiplexed IPdu contains ComIPduA. The value of the selector field in the dynamic part decides which content is transmitted. ComIPduB is transmitted if the selector field value is "0". ComIPduC is transmitted if the selector field value is "1".

The static and the dynamic part can consist of more than one element. These sub parts of the static or dynamic parts are called segments. In Figure 6.31 the dynamic Part is segmented into two parts. More details can be found in [23].

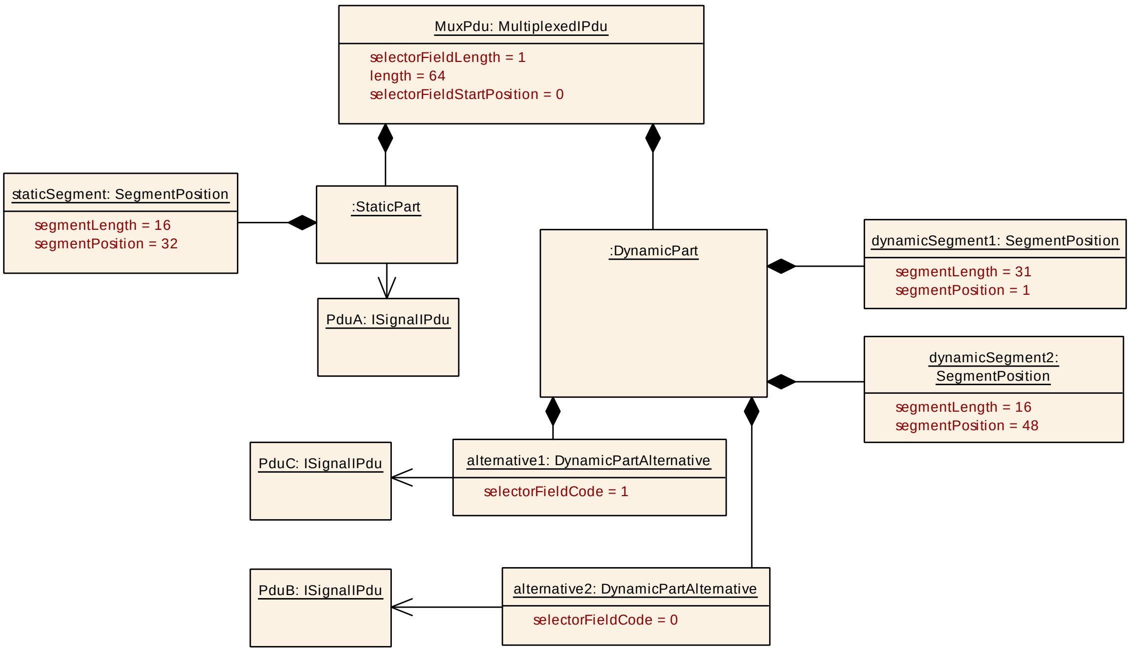

Figure 6.31: I-Pdu Multiplexer Example

Each of the following figures shows an example with an allowed IPduM configuration. Please note that the AUTOSAR IPduM module does not shift any part (static or dynamic) IPdu and just merges the payload. `ISignalIPdu`s that are referenced by the different `DynamicPartAlternative`s in one `MultiplexedIPdu` shall always have the same length. A configuration may be optimized with respect to unused data at end of a `StaticPart` `ISignalIPdu`. This is shown in figure 6.32 where the `ISignalIPdu` that is referenced by the `StaticPart` is shorter than the `MultiplexedIPdu`. An optimization with respect to unused data at end of `DynamicPartAlternative` `ISignalIPdu`s is shown in figure 6.33.

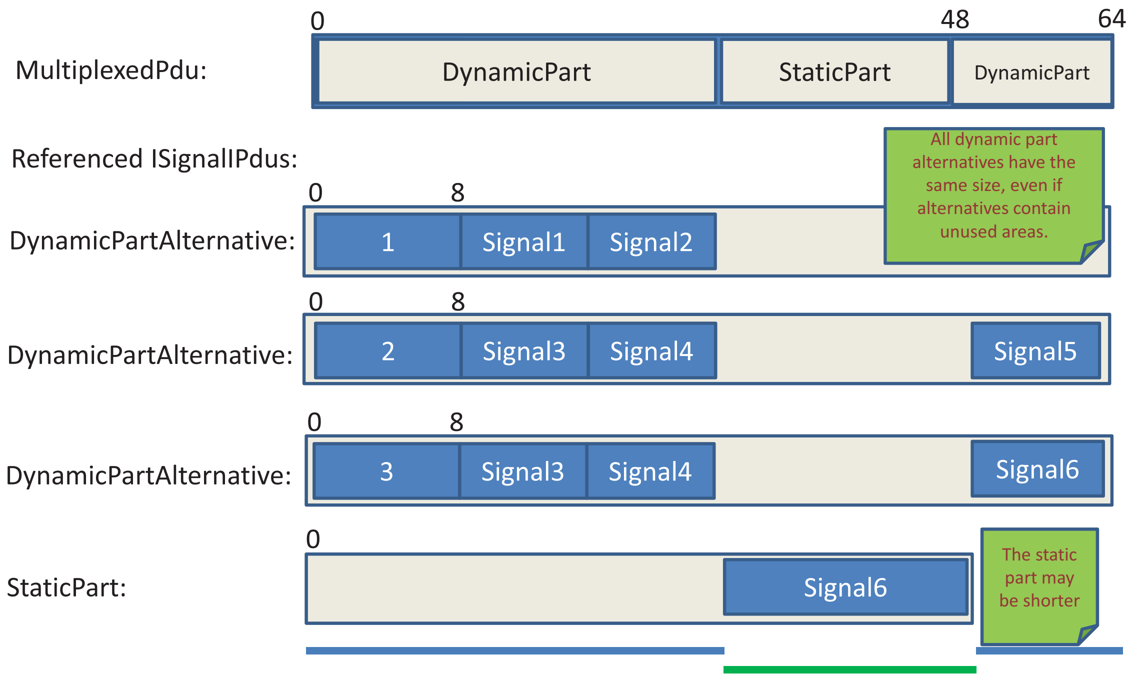

Figure 6.32: Multiplexer configuration example optimized with respect to unused data at end of static part Pdu

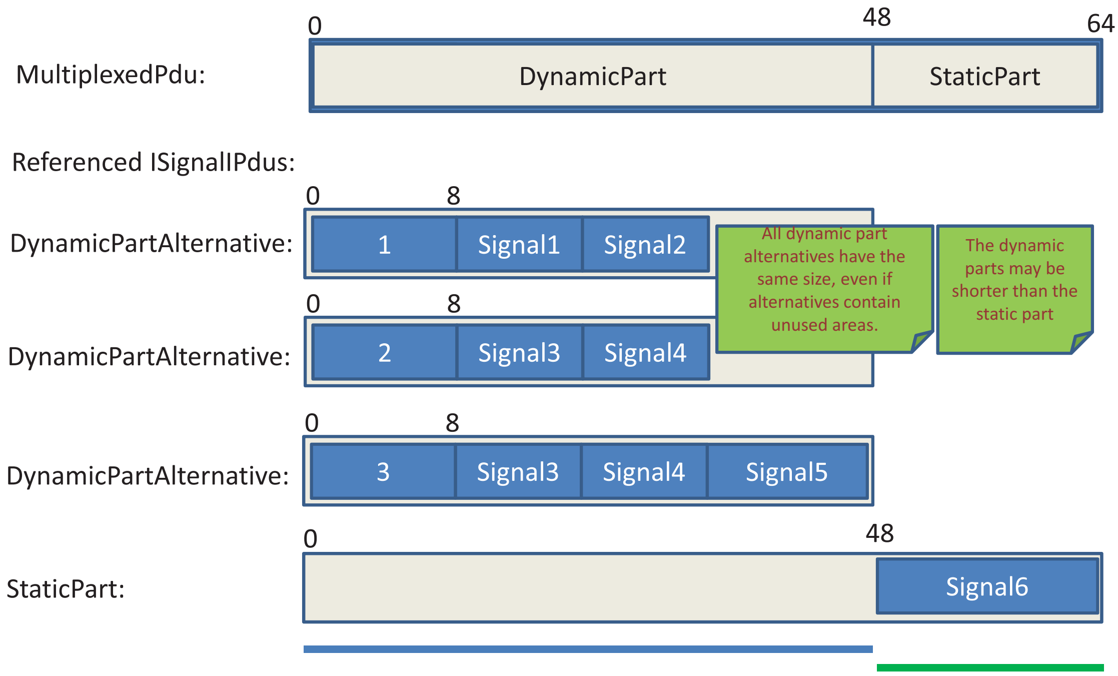

Figure 6.33: Multiplexer configuration example optimized with respect to unused data at end of dynamic part Pdus

6.5.1 I-Pdu Multiplexer in System Extract/ECU Extract

The processing in the ECU determines the description of MultiplexedIPdus in the System Extract/Ecu Extract. In case that a Gateway ECU only routes a MultiplexedIPdu without being interested in the content leads to a reduced description in the System Extract/ECU Extract. The following items describe the different scenarios and the consequences for the System Extract/ECU Extract description. A complete System Description contains all information.

[TPS_SYST_01080] Sending or receiving of a MultiplexedIPdu in System Extract/ECU Extract ⌈

- all attributes of the MultiplexedIPdu are mandatory
- aggregated DynamicPart with associated ISignalIPdus is mandatory in case
  - of sending
  - of receiving if at least one DynamicPartAlternative is received by one Ecu of the Extract.
- a PduTriggering shall be defined for the MultiplexedIPdu
- a PduTriggering shall be defined for all included ISignalIPdus in the DynamicPart and StaticPart

⌋

The initial ECU Configuration Generator configures COM, PduR, IpduM and lower layers with the information from the System Extract/ECU Extract.

[TPS_SYST_01081] Gatewaying of a MultiplexedIPdu in System Extract/ECU Extract ⌈

- StaticPart and DynamicPart definitions shall be omitted, thus no ISignalIPdu description shall be included
- all attributes of the MultiplexedIPdu shall be omitted.
- a PduTriggering shall be defined only for the gatewayed MultiplexedIPdu
- an IPduMapping between the source and the target PduTriggerings shall be defined

⌋

The initial ECU Configuration Generator configures PduR and lower layers with the information from the System Extract/ECU Extract.

[TPS_SYST_01082] Receiving and gatewaying of a MultiplexedIPdu in System Extract/ECU Extract ⌈

- all attributes of the MultiplexedIPdu are mandatory
- aggregated DynamicPart with associated ISignalIPdus is mandatory in case at least one DynamicPartAlternative is received by one Ecu of the Extract.
- a PduTriggering shall be defined for the MultiplexedIPdu
- an IPduMapping between the source and the target PduTriggerings shall be defined
- a PduTriggering shall be defined for all included ISignalIPdus in the DynamicPart and StaticPart

⌋

The initial ECU Configuration Generator configures Com, PduR, IpduM and lower layers with the information from the System Extract/ECU Extract.

6.6 Frames

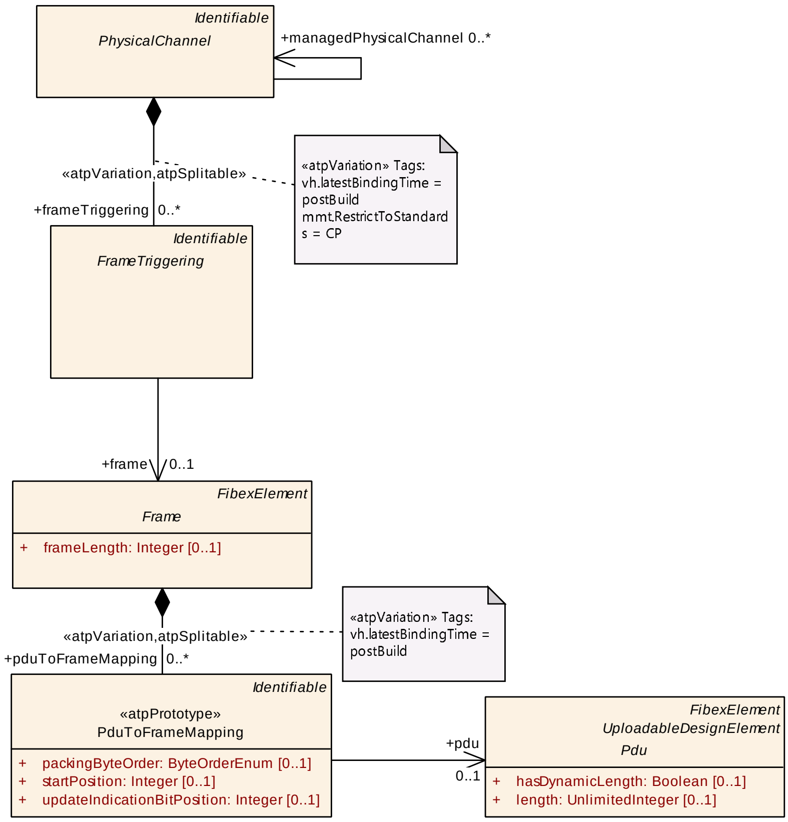

Figure 6.34: Frame Overview (FibexCore: FrameOverview)

[TPS_SYST_01083] `Frame` ⌈A `Frame` represents a general design object that is used to describe the layout of the included `Pdu`s as a reusable asset.⌋

[TPS_SYST_01084] `FrameTriggering` ⌈The `FrameTriggering` implements the reusable definition of a `Frame` within a concrete context and thus defines a `Frame`'s send behavior and identification on a certain `PhysicalChannel`.⌋

[TPS_SYST_02255] `Frame.frameLength` usage for `FlexrayFrame`s and `CanFrame`s ⌈The `frameLength` for a `FlexrayFrame` shall be equal or larger than the combined length of all `Pdu`s that are mapped to the frame.

The `frameLength` for a `CanFrame` is used to describe the minimum length of a received L-PDU to be accepted by a data length check. Therefore, it is possible to configure a `frameLength` which is smaller than the mapped `Pdu` to this frame. If data length check is not needed the `frameLength` of a `CanFrame` may be left undefined. The reason for that is that if the `CanFrame.frameLength` is larger than the `Pdu.length` of the mapped `Pdu` and data length check is used, a received `Pdu` will always be discarded due to a failing minimum length check.⌋

Class	***Frame*** (abstract)

6.7 Specialized Attributes of the Communication Entities

In the Basic Software the timing of bus frames can be controlled by send requests of the RTE in combination with the Transmission Mode and Transfer Property parameters in COM. On the other hand the timing can be controlled by the FlexRay Interface and LIN Interface.

This chapter describes the protocol specific extensions to the communication elements.

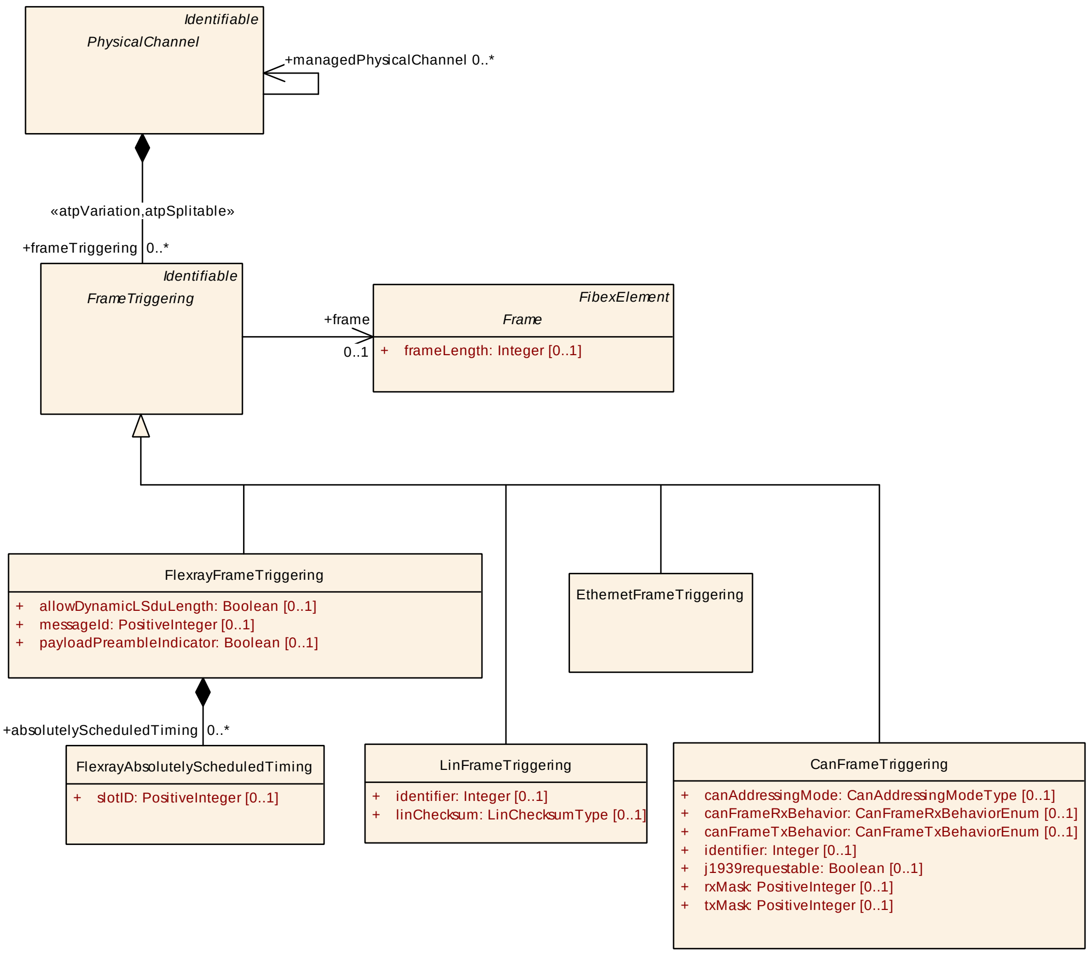

Figure 6.35: Frame Triggering

6.7.1 FlexRay specific description

[TPS_SYST_01128] Communication over FlexRay

Upstream requirements: RS_SYST_00024

⌈The System Template supports the description of communication over FlexRay.⌋

In the following, the elements necessary to describe the FlexRay communication are specified.

FlexRay static segment parameters: Each FlexrayFrameTriggering is identified by its slotID and communicationCycle. In the static segment all communication slots are of identical, statically configured duration and all FrameTriggerings are of identical, statically configured length.

The sending behavior where the exact time for the FlexrayFrameTriggerings transmission is guaranteed is provided in the System Template by the usage of FlexrayAbsolutelyScheduledTiming.

In the cycle counter field of every frame, the current value of the cycle counter is transmitted (see FlexRay frame format). This value is incremented at the beginning of each new cycle, ranging from 0 to 63, and is reset to 0 after a sequence of 64 cycles.

[TPS_SYST_01085] Transmission of a FrameTriggering multiple times within one communication cycle

Upstream requirements: RS_SYST_00024

⌈In the static segment FlexrayFrameTriggerings can be sent multiple times within one communication cycle. For describing this case multiple FlexrayAbsolutelyScheduledTimings shall be used.⌋

FlexRay dynamic segment parameters: In the dynamic segment the duration of communication slots may vary in order to accommodate frames of varying length. Furthermore, in the dynamic part, the slotID is equivalent to a priority. The higher the number the lower is the priority.

The frames in the static and in the dynamic segment are described in the same way. Each FlexrayFrameTriggering is identified by its slotID and communicationCycle. A description is provided by the usage of FlexrayAbsolutelyScheduledTiming.

Class	FlexrayAbsolutelyScheduledTiming			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Flexray::FlexrayCommunication			
Note	Each frame in FlexRay is identified by its slot id and communication cycle. A description is provided by the usage of AbsolutelyScheduledTiming. In the static segment a frame can be sent multiple times within one communication cycle. For describing this case multiple AbsolutelyScheduledTimings have to be used. The main use case would be that a frame is sent twice within one communication cycle.			
Base	*ARObject*			
Aggregated by	FlexrayFrameTriggering.absolutelyScheduledTiming			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
communication Cycle	CommunicationCycle	0..1	aggr	The communication cycle where the frame is sent.

▽

△

Class	FlexrayAbsolutelyScheduledTiming			
slotID	PositiveInteger	0..1	attr	In the static part the SlotID defines the slot in which the frame is transmitted. The SlotID also determines, in combination with FlexrayCluster::numberOfStaticSlots, whether the frame is sent in static or dynamic segment. In the dynamic part, the slot id is equivalent to a priority. Lower dynamic slot ids are all sent until the end of the dynamic segment. Higher numbers, which were ignored that time, have to wait one cycle and then shall try again. minValue: 1 maxValue: 2047

Table 6.83: FlexrayAbsolutelyScheduledTiming

[constr_3014] Overlapping of updateIndicationBits for Pdus is prohibited

Imposition time: IT_SysDesc

⌈The updateIndicationBitPosition for a Pdu in a FlexrayFrame shall NOT overlap with other updateIndicationBitPositions and Pdu locations.⌋

[constr_5104] Assignment of a FlexrayFrame where allowDynamicLSduLength is set to true

Imposition time: IT_SysDesc

⌈FlexrayFrames which are referenced by a FlexrayFrameTriggering where allowDynamicLSduLength is set to true shall always be assigned to the dynamic segment.⌋

[constr_5105] Mapping of Pdu with dynamic length in a FlexrayFrame

Imposition time: IT_SysDesc

⌈Only the last Pdu in a FlexrayFrame is allowed to qualify according to [TPS_SYST_03085] to be of dynamic length.⌋

Note: Please be aware that the dynamic Pdu at the end of the FlexRay Frame may need to provide some mechanism to determine its actual length (e.g. length field, termination). Otherwise the receiver is not able to determine the actual sent length.

6.7.2 LIN specific description

LIN is a protocol that is based on a single master - multiple slave principle. In the following, the parameters will be specified, which are necessary to describe the LIN Schedule Tables and the LIN Frames.

[TPS_SYST_01129] Communication over LIN

Upstream requirements: RS_SYST_00022

⌈The System Template supports the description of communication over LIN.⌋

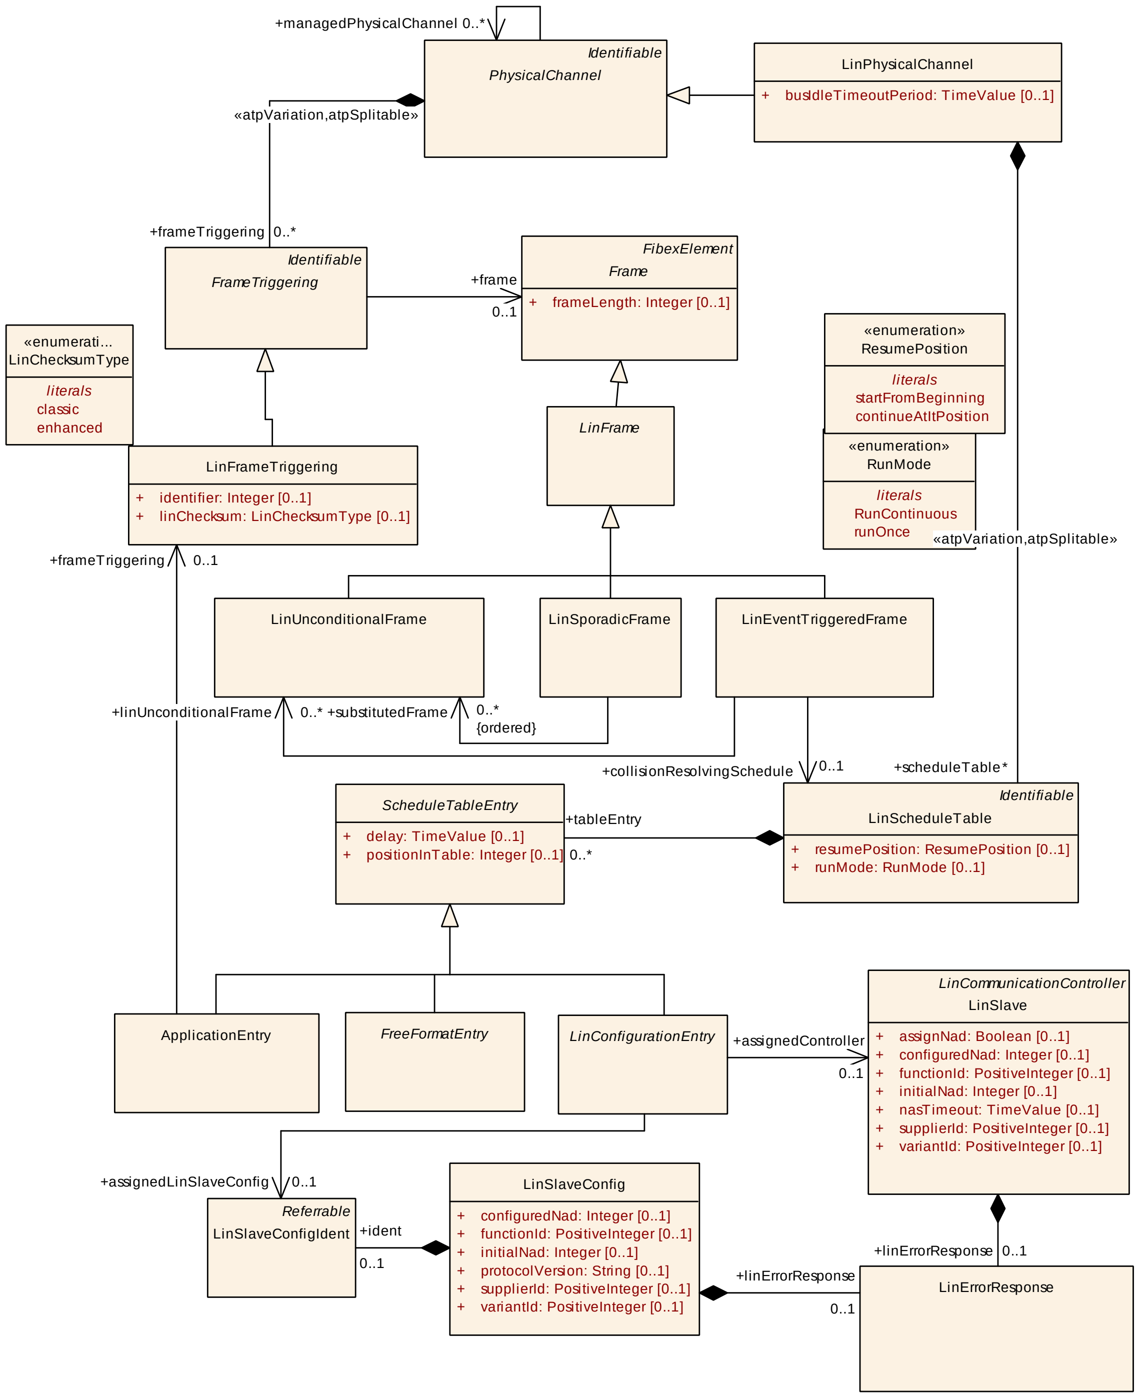

Figure 6.37: LIN Schedule Table (Fibex4Lin:LinScheduleTable)

6.7.2.1 LIN Frames

One LIN Frame consists of two parts: header and response. The header is always sent by a `LinMaster`, while the response is sent by only one dedicated `LinSlave`. There are three different ways of transmitting frames on the bus: unconditional, event triggered, and sporadic frames.

Class	***LinFrame*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	Lin specific Frame element.

[constr_3226] LinFrameTriggering.linChecksum for LinEventTriggeredFrames

Imposition time: IT_SysDesc

⌈Within a PhysicalChannel the linChecksum attribute of a LinFrameTriggering that references a LinEventTriggeredFrame shall have the same value as the linChecksum attribute of each LinFrameTriggering that references a LinUnconditionalFrame that in turn is referenced by that LinEventTriggeredFrame.⌋

[constr_3203] LinFrameTriggering to LinSporadicFrame reference restriction in LinSporadicFrame context

Imposition time: IT_SysDesc

⌈Within a PhysicalChannel a LinUnconditionalFrame shall be referenced by only one LinFrameTriggering to allow a derivation of the identifier of a substituted Frame if the LinUnconditionalFrame is referenced by a LinSporadicFrame in the role substitutedFrame.⌋

Class	LinSporadicFrame
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication
Note	A sporadic frame is a group of unconditional frames that share the same frame slot. The sporadic frame shall not contain any Pdus. **Tags:** atp.recommendedPackage=Frames
Base	*ARObject*, *CollectableElement*, *FibexElement*, *Frame*, *Identifiable*, *LinFrame*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*

▽

△

Class	LinSporadicFrame			
Aggregated by	ARPackage.element			
Attribute	Type	Mult.	Kind	Note
substituted Frame (ordered)	LinUnconditionalFrame	*	ref	Reference to a group of unconditional frames that share the same frame slot. In case that more than one of the declared frames needs to be transferred, the one first listed shall be chosen. Within a channel a LIN Frame shall be referenced by only one FrameTriggering. This allows a derivation of the identifier of a substituted Frame. The identifier is specified in FrameTriggering element. A LinUnconditionalFrame associated with a LinSporadic Frame may not be allocated in the same LinSchedule Table as the sporadic frame.

Table 6.92: LinSporadicFrame

[constr_3204] LinUnconditionalFrames associated with a LinSporadicFrame

Imposition time: IT_SysDesc

⌈A LinUnconditionalFrame associated with a LinSporadicFrame shall not be allocated in the same LinScheduleTable as the LinSporadicFrame.⌋

[constr_3205] Existence of FramePort for a FrameTriggering that references a LinSporadicFrame

Imposition time: IT_SysDesc

⌈A FrameTriggering that references a LinSporadicFrame shall not have a reference to a FramePort.⌋

[constr_9132] Existence of LinSporadicFrame.substitutedFrame

Imposition time: IT_SysDesc

⌈For each LinSporadicFrame, at least one reference to LinUnconditionalFrame in the role substitutedFrame shall exist.⌋

Instead of the LinSporadicFrame a LinUnconditionalFrame is sent in the timeslot on the bus and therefore the FrameTriggering that references a LinSporadicFrame does not need to have a reference to a FramePort.

Class	LinEventTriggeredFrame			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	An event triggered frame is used as a placeholder to allow multiple slave nodes to provide its response. The header of an event triggered frame is transmitted when a frame slot allocated to the event triggered frame is processed. The publisher of an associated unconditional frame shall only transmit the response if at least one of the signals carried in its unconditional frame is updated. The LIN Master discovers and purges collisions with the collisionResolvingScheduleTable. The event controlled frame shall not contain any Pdus. **Tags:** atp.recommendedPackage=Frames			
Base	*ARObject*, *CollectableElement*, *FibexElement*, *Frame*, *Identifiable*, *LinFrame*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
collision Resolving Schedule	LinScheduleTable	0..1	ref	Reference to the schedule table, which resolves a collision.
linUnconditional Frame	LinUnconditionalFrame	*	ref	A list of slaves can respond to the master request if at least one of the signals carried in its unconditional frame is updated. For each response a LinFrameTriggering and a LinUnconditionalFrame shall be defined. Within a channel a LIN Frame shall be referenced by only one FrameTriggering. This allows a derivation of the identifier of a substituted Frame. The identifier is specified in FrameTriggering element. The Unconditional frames associated with an event triggered frame shall: • have equal length. • use the same checksum model (i.e. mixing LIN 1.x and LIN 2.x frames is not allowed). • reserve the first data field to its protected identifier (even if the associated unconditional frame is scheduled as a unconditional frame in the same or another schedule table). • be published by different slave nodes. • shall not be included directly in the same schedule table as the event triggered frame is scheduled.

Table 6.93: LinEventTriggeredFrame

[TPS_SYST_02077] Subscribers of a `LinEventTriggeredFrame` ⌈For each subscriber of a `LinEventTriggeredFrame` a `LinUnconditionalFrame` and a `LinFrameTriggering` that points to this `LinUnconditionalFrame` shall be defined.⌋

[constr_3202] `LinFrameTriggering` to `LinUnconditionalFrame` reference restriction in `LinEventTriggeredFrame` context

Imposition time: `IT_SysDesc`

⌈Within a `PhysicalChannel` a `LinUnconditionalFrame` shall be referenced by only one `LinFrameTriggering` to allow a derivation of the identifier of a substituted Frame if the `LinUnconditionalFrame` is referenced by a `LinEventTriggeredFrame` in the role `linUnconditionalFrame`.⌋

[constr_3206] Existence of FramePort for a FrameTriggering that references a LinEventTriggeredFrame

Imposition time: IT_SysDesc

⌈A FrameTriggering that references a LinEventTriggeredFrame shall not have a reference to a FramePort.⌋

[constr_9133] Existence of LinEventTriggeredFrame.linUnconditionalFrame

Imposition time: IT_SysDesc

⌈For each LinEventTriggeredFrame, at least one reference to LinUnconditionalFrame in the role linUnconditionalFrame shall exist.⌋

A LinUnconditionalFrame is sent as the response of a LinEventTriggeredFrame on the bus instead and therefore the FrameTriggering that references a LinEventTriggeredFrame does not need to have a reference to a FramePort.

[TPS_SYST_02078] LinUnconditionalFrames associated with a LinEventTriggeredFrame ⌈The LinUnconditionalFrames associated with a LinEventTriggeredFrame shall:

- have equal length
- use the same checksum model (i.e. mixing LIN 1.x and LIN 2.x frames is not allowed)
- reserve the first data field to its protected identifier (even if the associated LinUnconditionalFrame is scheduled as a LinUnconditionalFrame in the same or another schedule table)
- be published by different slave nodes
- not be included directly in the same LinScheduleTable as the associated LinEventTriggeredFrame.

⌋

6.7.2.2 LIN Schedule Table

The LinMaster uses one or more predefined scheduling tables to start the sending and receiving to the LIN bus. These scheduling tables contain at least the relative timing that defines the message sending.

[constr_1657] Existence of LinPhysicalChannel.scheduleTable

Imposition time: IT_SysDesc

⌈In any given Ecu Extract that contains a LinSlave, the LinPhysicalChannel that relates to the respective LinSlave via commConnector.commController shall not aggregate a LinScheduleTable.⌋

Class	**LinScheduleTable**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	The master task (in the master node) transmits frame headers based on a schedule table. The schedule table specifies the identifiers for each header and the interval between the start of a frame and the start of the following frame.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	LinPhysicalChannel.scheduleTable			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
resumePosition	ResumePosition	0..1	attr	Defines, where a schedule table shall be proceeded in case if it has been interrupted by a run-once table or MRF/SRF.
runMode	RunMode	0..1	attr	The schedule table can be executed in two different modes.
tableEntry	ScheduleTableEntry	*	aggr	The scheduling table consists of table entries, which contain Frame slots.

Class	***LinConfigurationEntry*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	A ScheduleTableEntry which contains LIN specific assignments.			
Base	*ARObject*, *ScheduleTableEntry*			
Subclasses	AssignFrameId, AssignFrameIdRange, AssignNad, ConditionalChangeNad, DataDumpEntry, SaveConfigurationEntry, UnassignFrameId			
Aggregated by	LinScheduleTable.tableEntry			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
assignedController	LinSlave	0..1	ref	The LIN slaves controller who is target of this assignment. Optional in case LinConfigurationEntry.assignedLinSlaveConfig exists.
assignedLinSlaveConfig	LinSlaveConfigIdent	0..1	ref	The LIN slave that is target of this assignment. Please note that this reference is redundant to the assignedController reference. In an Ecu Extract of the LinMaster the LinSlave Ecus shall not be available. The information that is described here is necessary in the ECU Extract for the configuration of the LinMaster.

Table 6.100: LinConfigurationEntry

6.7.2.3 Configuration Services

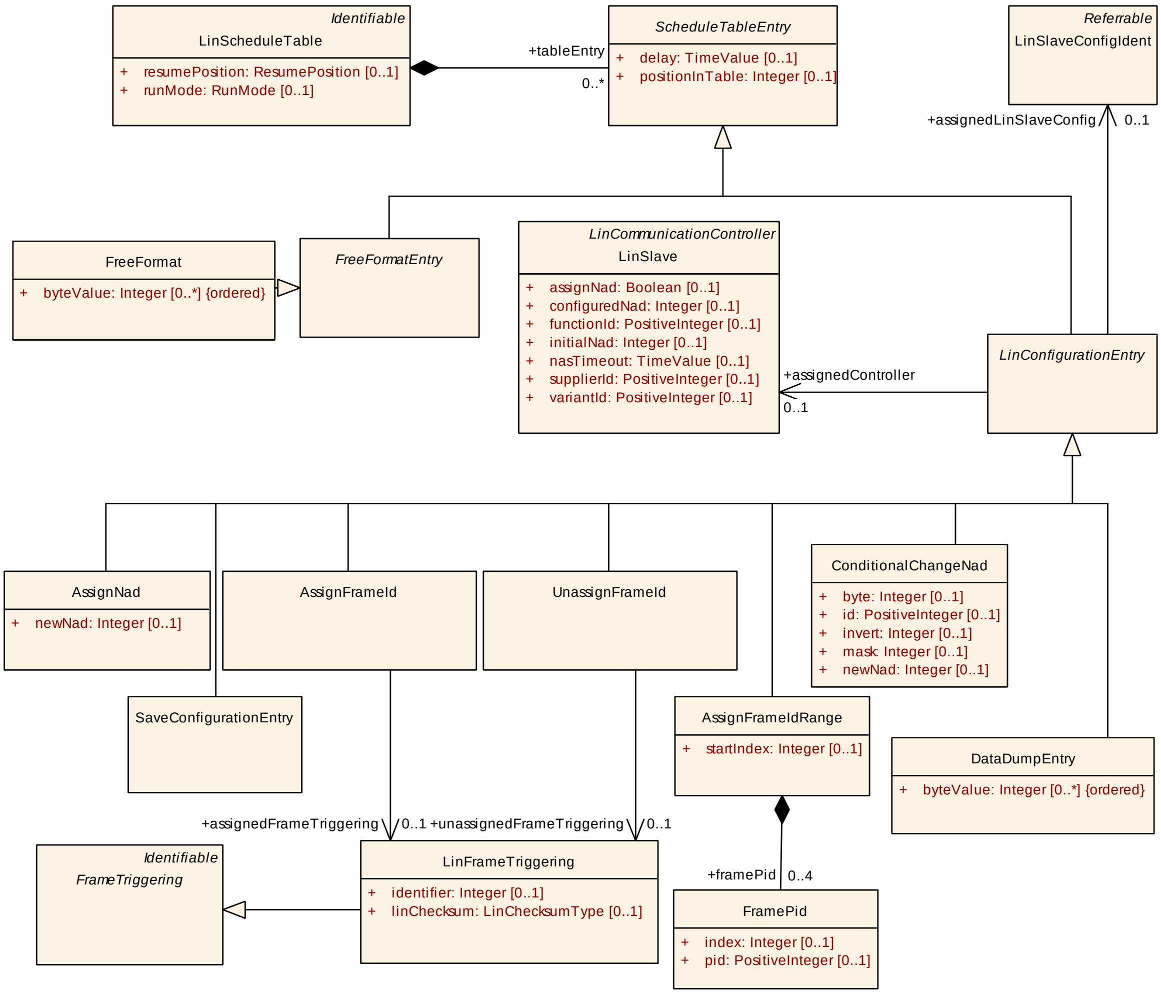

Figure 6.38: LIN Configuration Entries (Fibex4Lin:LinConfigurationEntries)

LIN only supports 64 identifiers. That creates the need for extending the address space. Hence the frames are identified by message ids from a much larger address space that is additionally separated by supplier ids. During runtime the master assigns a LinId to the frame. In case of identical parts within a cluster the initial node ID (oldNad) is used to differentiate such nodes.

To support that in System Template the `AssignFrameId` is introduced as a LIN specific extension. For the assignment a relation to the `LinSlave` is used. The `LinSlave` element is referenced by a `LinCommunicationConnector` element that contains a list of frames processed by the slave node.

Class	**AssignFrameId**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication
Note	Schedule entry for an Assign Frame Id master request.
Base	*ARObject*, *LinConfigurationEntry*, *ScheduleTableEntry*

assignedFrame Triggering	LinFrameTriggering	0..1	ref	The frame whose identifier is set by this assignment.

Table 6.101: AssignFrameId

Class	**UnassignFrameId**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	Schedule entry for an Unassign Frame Id master request where the protected identifier is assigned the value 0x40. This will disable reception/transmission of a previously dynamically assigned frame identifier.			
Base	*ARObject*, *LinConfigurationEntry*, *ScheduleTableEntry*			
Aggregated by	LinScheduleTable.tableEntry			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
unassigned FrameTriggering	LinFrameTriggering	0..1	ref	The frame whose identifier is reset by this assignment.

Table 6.102: UnassignFrameId

[constr_9137] Existence of `AssignFrameId.assignedFrameTriggering`

Imposition time: `IT_SysDesc`

⌈For each `AssignFrameId`, the reference to `LinFrameTriggering` in the role `assignedFrameTriggering` shall exist.⌋

[constr_9138] Existence of `UnassignFrameId.unassignedFrameTriggering`

Imposition time: `IT_SysDesc`

⌈For each `UnassignFrameId`, the reference to `LinFrameTriggering` in the role `unassignedFrameTriggering` shall exist.⌋

[TPS_SYST_02363] `messageId` of `AssignFrameId` and `UnassignFrameId` ⌈In case that the `AssignFrameId` or `UnassignFrameId` refers to a `LinSlave` in the role `assignedController` the `messageId` of the `AssignFrameId`/`UnassignFrameId` can be derived from the `messageId` of the `LinConfigurableFrame` that references the same `LinFrame` as the `LinFrameTriggering` that is referenced by the `AssignFrameId`/`UnassignFrameId` and that is aggregated by the `LinCommunicationConnector` in role `linConfigurableFrame` that points to this `LinSlave` in the role `commController`.

In case that the `AssignFrameId`/`UnassignFrameId` refers to a `LinSlaveConfigIdent` in the role `assignedLinSlaveConfig` the `messageId` of the `AssignFrameId`/`UnassignFrameId` can also be derived from the `messageId` of the `LinConfigurableFrame` that references the same `LinFrame` as the `LinFrameTriggering` that is referenced by the `AssignFrameId`/`UnassignFrameId` and that is aggregated by the referenced `LinSlaveConfig`.⌋

The Assign frame ID configuration service is replaced in LIN 2.1 by the Assign frame ID range configuration service. AssignFrameIdRange is used to set or disable Protected Identifiers up to four frames. For the assignment a relation to the LinSlave is used. The LinSlave element is referenced by a LinCommunicationConnector element that contains a list of frames processed by the slave node.

Class	**AssignFrameIdRange**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	AssignFrameIdRange generates an assign frame PID range request.			
Base	*ARObject*, *LinConfigurationEntry*, *ScheduleTableEntry*			
Aggregated by	LinScheduleTable.tableEntry			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
framePid	FramePid	0..4	aggr	Optional assignment of frame_PID values that are included in the request. The frame_PIDs are ordered.
startIndex	Integer	0..1	attr	The startIndex sets the index to the first frame to assign a PID.

Table 6.103: AssignFrameIdRange

[constr_9139] Existence of AssignFrameIdRange.startIndex

Imposition time: IT_SysDesc

⌈For each AssignFrameIdRange, the attribute startIndex shall exist.⌋

Class	**FramePid**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Lin::LinCommunication			
Note	Frame_PIDs that are included in the request. The "pid" attribute describes the value and the "index" attribute the position of the frame_PID in the request.			
Base	*ARObject*			
Aggregated by	AssignFrameIdRange.framePid			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
index	Integer	0..1	attr	This attribute is used to order the frame_PIDs. The values of index shall be unique within one AssignFrameIdRange.
pid	PositiveInteger	0..1	attr	Frame_PID value.

Table 6.104: FramePid

Table 6.109: FreeFormat

[constr_9149] Existence of FreeFormat.byteValue

Imposition time: IT_SysDesc

⌈For each FreeFormat, 8 byteValues shall be defined.⌋

In order to be consistent with the rest of the communication configuration, it is required that the diagnostic LIN Frames (Master Request Frame, Slave Response Frame) are explicitly modeled as Frame elements. LinFrameTriggerings dealing with diagnostic Frames thus reference this diagnostic frames.

[TPS_SYST_02276] Modeling of LIN master request frames ⌈A LIN master request frame shall be modeled per LinPhysicalChannel in terms of a LinFrameTriggering referencing a LinUnconditionalFrame while the following rules apply:

- The LinFrameTriggering has identifier set to 60 (0x3C) and linChecksum set to classic.
- The LinFrameTriggering has a reference to an “out” FramePort of the LinMaster and “in” FramePorts of the respective LinSlaves in the scope of the same LinPhysicalChannel.
- The LinFrameTriggering references a LinUnconditionalFrame with frameLength set to 8.
- The LinFrameTriggering references a PduTriggering that in turn references a NPdu that is mapped to the LinUnconditionalFrame and that has its length set to 8. The NPdu is referenced by a LinTpConnection in the role dataPdu.

- The PduTriggering has a reference to an “out” IPduPort of the LinMaster and “in” IPduPorts of the respective LinSlaves in the scope of the same LinPhysicalChannel.

⌋

[TPS_SYST_02277] Modeling of LIN slave response frames ⌈A LIN slave response frame shall be modeled per LinPhysicalChannel in terms of a LinFrameTriggering referencing a LinUnconditionalFrame while the following rules apply:

- The LinFrameTriggering has identifier set to 61 (0x3D) and linChecksum set to classic.
- The LinFrameTriggering has a reference to an “in” FramePort of the LinMaster and “out” FramePorts of the respective LinSlaves in the scope of the same LinPhysicalChannel.
- The LinFrameTriggering references a LinUnconditionalFrame with frameLength set to 8.
- The LinFrameTriggering references a PduTriggering that in turn references a NPdu that is mapped to the LinUnconditionalFrame and that has its length set to 8. The NPdu is referenced by a LinTpConnection in the role dataPdu.
- The PduTriggering has a reference to an “in” IPduPort of the LinMaster and “out” IPduPorts of the respective LinSlaves in the scope of the same LinPhysicalChannel.

⌋

6.7.3 CAN specific description

This chapter describes additions to the CAN definition of FrameTriggerings.

[TPS_SYST_01130] Communication over CAN

Upstream requirements: RS_SYST_00021

⌈The System Template supports the description of communication over CAN.⌋

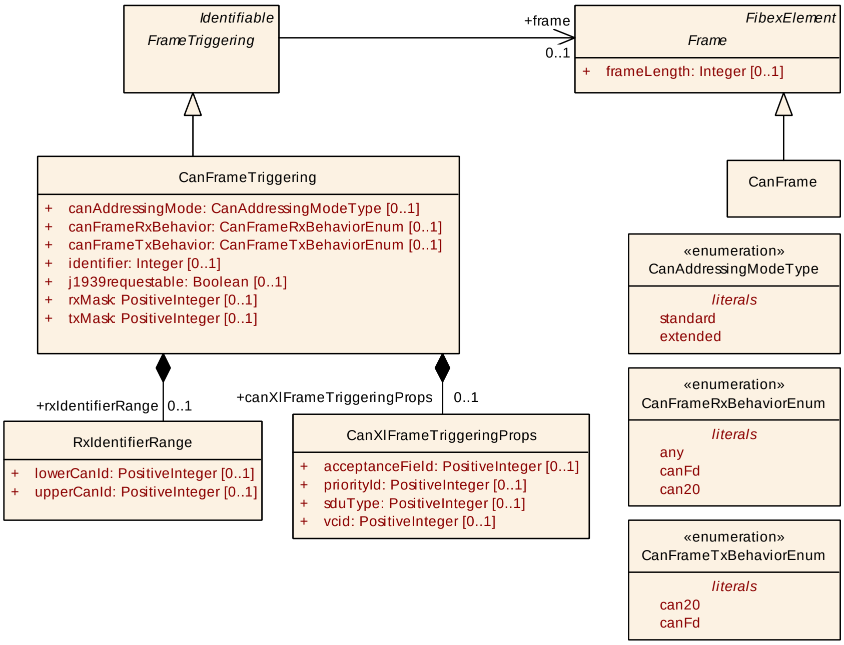

Figure 6.39: CanFrameTriggering (Fibex4Can:CanCommunication)

Class	**CanFrame**

lowerCanId	PositiveInteger	0..1	attr	This attribute can be used together with the upperCanId attribute to define a range of CanIds.
upperCanId	PositiveInteger	0..1	attr	This attribute can be used together with the lowerCanId attribute to define a range of CanIds.

Table 6.113: RxIdentifierRange

[constr_9101] Existence of RxIdentifierRange.lowerCanId

Imposition time: IT_SysDesc

⌈For each RxIdentifierRange, the attribute lowerCanId shall exist.⌋

[constr_9102] Existence of RxIdentifierRange.upperCanId

Imposition time: IT_SysDesc

⌈For each RxIdentifierRange, the attribute upperCanId shall exist.⌋

Enumeration	CanFrameRxBehaviorEnum
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Can::CanCommunication
Note	Defines different CAN protocols for frame reception behavior.
Aggregated by	CanFrameTriggering.canFrameRxBehavior
Literal	**Description**
any	This CAN frame may be received as both, CAN 2.0 and CAN FD. **Tags:** atp.EnumerationLiteralIndex=0
can20	This CAN frame shall be received as CAN 2.0 only. In case the CAN frame is received as CAN FD it is discarded during reception. **Tags:** atp.EnumerationLiteralIndex=1
canFd	This CAN frame shall be received as CAN FD only. In case the CAN frame is received as CAN 2.0 it is discarded during reception. **Tags:** atp.EnumerationLiteralIndex=2

Table 6.114: CanFrameRxBehaviorEnum

There exist use-cases where the CanFrameTriggering is used as a placeholder for a variant number of actual Can frames and therefore no dedicated CAN identifier can be defined (e.g. MetaData handling, Bus Mirroring).

[TPS_SYST_02201] Existence of CanFrameTriggering.identifier ⌈In a System with category SYSTEM_DESCRIPTION the identifier may be omitted if the value is computed during runtime. In a System with category ECU_EXTRACT, ECU_SYSTEM_DESCRIPTION or SYSTEM_EXTRACT for the transmitter the identifier may be omitted if the value is computed during runtime. In an System with category ECU_EXTRACT, ECU_SYSTEM_DESCRIPTION or SYSTEM_EXTRACT for the receiver the identifier may be omitted if rxIdentifierRange is defined.⌋

[constr_9318] Reception of CanFrameTriggerings with the same identifier by an EcuInstance

Imposition time: IT_SysDesc

⌈For all CanFrameTriggerings on the same PhysicalChannel that refer to a FramePort with the communicationDirection = in of the same EcuInstance the condition applies that no two of these CanFrameTriggerings shall have the same identifier and the same canAddressingMode assigned.⌋

In other words an EcuInstance shall not receive two CanFrameTriggerings with the same identifier and the same canAddressingMode in a variant bound model. This constraint was introduced to the System Template to detect misconfiguration issues in the CanIf module in an early development phase.

[TPS_SYST_02256] Allowed CanFrame.frameLength settings ⌈For a CanFrame it is allowed to configure a smaller frameLength than the length of the Pdu which is mapped to this CanFrame. This is used to model the minimum length of the received L-PDU of a CanFrame to be accepted, if the data length check is enabled.⌋

The CanFrameTriggering.canFrameRxBehavior allows to define a tolerant CAN FD reception strategy. With the setting any the respective CAN frame is accepted for reception, regardless whether it is received with CAN FD or CAN 2.0 protocol.

Enumeration	**CanFrameTxBehaviorEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Can::CanCommunication
Note	Defines different CAN protocols for frame transmission behavior.
Aggregated by	CanFrameTriggering.canFrameTxBehavior, IEEE1722TpAcfCanPart.canFrameTxBehavior
Literal	***Description***
can20	This CAN frame shall be sent as CAN 2.0 only. **Tags:** atp.EnumerationLiteralIndex=0
canFd	This CAN frame shall be sent as CAN FD. **Tags:** atp.EnumerationLiteralIndex=1

Table 6.115: CanFrameTxBehaviorEnum

Note that the transmission behavior of CanFrameTriggering.canFrameTxBehavior may still be redefined in the communication stack on driver level.

[TPS_SYST_02168] MetaData support required if CanFrameTriggering.txMask is used ⌈The usage of CanFrameTriggering.txMask requires the support of COM Stack MetaData.⌋

Please note that the MetaData support in [TPS_SYST_02168] is required to calculate CAN-Ids at run-time.

[TPS_SYST_02169] MetaData support may be required if `CanFrameTriggering.rxMask` is used ⌈The usage of `CanFrameTriggering.rxMask` may require the support of COM Stack MetaData.⌋

Please note that the MetaData support in [TPS_SYST_02169] is required if the upper layer is interested in the masked part of CAN-Id, e.g. J1939. In some cases the upper layer is not interested in the masked part of CAN-Id, e.g. for CanNm the MetaData is not required.

6.7.3.1 SAE J1939 Protocol specific description

J1939 is a protocol and application layer standard of the SAE (Society of Automotive Engineers) based on the CAN technology. It defines parameters uniquely identified by the SPN (Suspect Parameter Number). These are mapped to parameter groups that are uniquely identified by a PGN (Parameter Group Number). Parameters are simply handled as SystemSignals which have a name derived from the name of the SPNs. A Parameter Group (PG) corresponds to an IPdu.

J1939 uses extended 29 bit CAN identifiers to encode a priority, the source address of the frame, and a frame ID which is based on the PGN (Parameter Group Number) and may contain the destination address.

J1939 supports IPdus with more than 8 bytes, and IPdus with variable length that may exceed 8 bytes. As soon as an IPdu has more than 8 bytes, it does not fit in a single CAN frame and a transport protocol shall be used. Variable length IPdus will always be handled by the J1939 TP, regardless of the actual length. The J1939 Transport Protocol is described in chapter 6.8.8.

[TPS_SYST_01132] Communication over SAE J1939

Upstream requirements: RS_SYST_00038

⌈The System Template supports the description of communication over SAE J1939.⌋

[constr_3209] CanFrameTriggerings with identical PGN

Imposition time: IT_SysDesc

⌈For all CanFrameTriggerings where the attribute identifier contains the identical PGN (as defined in section 5.2 Protocol Data Unit in [24]) the attribute j1939requestable shall also have an identical value.⌋

6.7.3.2 CAN XL specific description

CAN XL is a continued development of CAN FD and standardized by the *Special Interest Group (SIG) CAN XL* of the *CAN in Automation (CiA)* association. It features a transmission speed of up to 20 MBit/s and large payloads (up to 2048 bytes) to offer a cost-effective alternative to Ethernet 10BASE network technology.

To ease the migration of an Ethernet based communication design to CAN XL, the feature of tunneling Ethernet frames through CAN XL based physical connections has also been standardized by the CiA association. The required system-level configuration for this use case is described in Ch. 3.3.1.2.2.

[TPS_SYST_03075] Communication over CAN XL ⌈The System Template supports the description of communication over CAN XL.⌋

Since CAN XL requires definition of additional specific configuration parameters on the physical layer which are relevant on system level, a few extensions to some elements of the System Template have been defined. They are described in the following.

[TPS_SYST_03076] Definition of CAN XL frame triggering attributes ⌈If a CanFrameTriggering relates to a CAN XL frame, then canXlFrameTriggeringProps as well as the relevant attributes contained in the aggregated class CanXlFrameTriggeringProps shall be defined accordingly. The absence of CanXlFrameTriggeringProps indicates a CanFrameTriggering for a non-CAN-XL frame.⌋

Please note that the relevance of the attributes of CanXlFrameTriggeringProps depends on the SDU Type and is specified by the *CiA* standardization of CAN XL. Additionally, a CanXlFrameTriggeringProps defined without any attributes is also valid meaning that the associated CAN Controller is capable of CAN XL and gets these attribute values by meta-data and/or is operating in backward compatibility mode (i.e. sending/receiving only Classical CAN or CAN FD frames).

[constr_3704] Existence of CanXlFrameTriggeringProps

Imposition time: IT_SysDesc

⌈If the class CanXlFrameTriggeringProps is aggregated by a CanFrameTriggering, then the CanCommunicationController – which is referenced through commController by a CanCommunicationConnector which in turn is referenced through commConnector by a CanPhysicalChannel that aggregates the aforementioned CanFrameTriggering – shall aggregate at least one of

- CanControllerConfiguration with CanControllerXlConfiguration aggregated or

- CanControllerConfigurationRequirements with CanControllerXl-ConfigurationRequirements aggregated.

⌋

[constr_3713] Allowed values for acceptanceField

Imposition time: IT_SysDesc

⌈The value for acceptanceField shall be in the range between 0 and 4294967295.⌋

[constr_3705] Allowed values for priorityId

Imposition time: IT_SysDesc

⌈The value for priorityId shall be in the range between 0 and 2047.⌋

[constr_3706] Allowed values for sduType

Imposition time: IT_SysDesc

⌈The value for sduType shall be in the range between 0 and 255.⌋

[constr_3707] Allowed values for vcid

Imposition time: IT_SysDesc

⌈The value for vcid shall be in the range between 0 and 255.⌋

Please note: Since it is possible to concurrently operate CAN FD and CAN XL nodes in the same network, the attributes of CanFrameTriggering related to CAN FD are also relevant in case this mixed network use case is to be realized.

Please note that figure 6.39 shows the modeling of CanXlFrameTriggeringProps.

6.7.4 TTCAN specific description

This chapter describes additions to the TTCAN definition of FrameTriggerings.

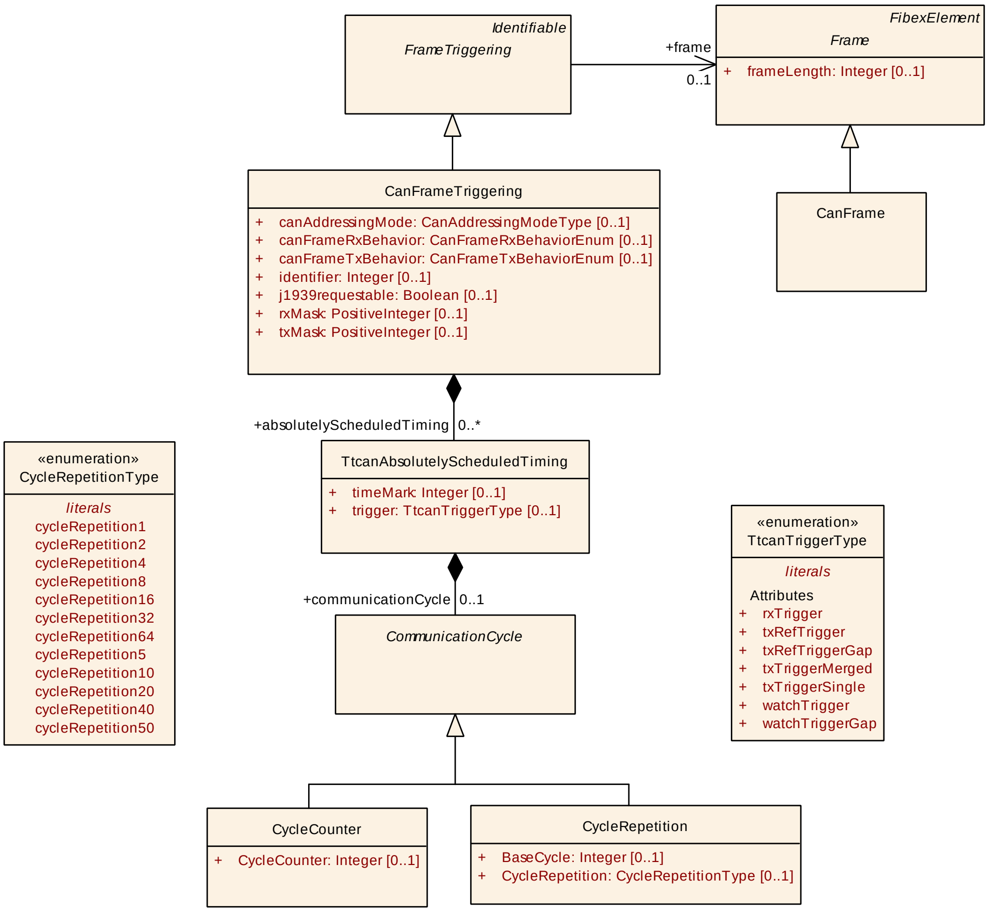

Figure 6.40: TtcanAbsolutelyScheduledTiming (Fibex4Ttcan:TtcanCommunication)

Class	TtcanAbsolutelyScheduledTiming			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ttcan::TtcanCommunication			
Note	Each frame in TTCAN is identified by its slot id and communication cycle. A description is provided by the usage of AbsolutelyScheduledTiming. A frame can be sent multiple times within one communication cycle. For describing this case multiple AbsolutelyScheduledTimings have to be used. The main use case would be that a frame is sent twice within one communication cycle.			
Base	*ARObject*			
Aggregated by	CanFrameTriggering.absolutelyScheduledTiming			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
communication Cycle	CommunicationCycle	0..1	aggr	The communication cycle where the frame is sent.

6.7.5 Ethernet specific description

Important note: Please note that the model of Release 4.4.0 to describe the Ethernet communication can still be used in the current release. Elements like SocketConnectionBundle and SocketConnection are set to obsolete and will be removed in a future release. The documentation of the old model is available in the Rel. 4.4.0 System Template specification. For the usage of the Rel. 4.4.0 model only the attributes that are described in Release 4.4.0 are valid. A mixture of the current release and Rel. 4.4.0 models is not allowed.

This chapter specifies how the data communication between nodes in an IP network over TCP and UDP protocols is described with an AUTOSAR model.

[TPS_SYST_01091] Definition of SoAdConfig

Upstream requirements: RS_SYST_00039

⌈The SoAdConfig in the System Template is defined per EthernetPhysicalChannel which represents a VLAN.⌋

The SoAdConfig element is the entry point for the description of the IP communication on a VLAN since it contains a collection of SocketAddresses of nodes that are able to receive and transmit information over the VLAN. Each node is represented by an EcuInstance. The SocketAddress defines a communication endpoint (IP Unicast or IP Multicast) and assigns it to one EthernetCommunicationConnector of an EcuInstance in case of IP Unicast communication and to one or several EthernetCommunicationConnectors in case of IP Multicast.

Class	**SoAdConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	SoAd Configuration for one specific Physical Channel.			
Base	*ARObject*			
Aggregated by	EthernetPhysicalChannel.soAdConfig			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
connection	SocketConnection	*	aggr	This aggregation is obsolete and will be removed in the future. The connectionGroup aggregation with bundled Connections shall be used instead. Old description: Collection of socket connections. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=connection, connection.variationPoint.shortLabel atp.Status=obsolete vh.latestBindingTime=postBuild

▽

△

Class	SoAdConfig			
connection Bundle	SocketConnection Bundle	*	aggr	Collection of SocketConnectionBundles. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=connectionBundle.shortName, connection Bundle.variationPoint.shortLabel atp.Status=obsolete vh.latestBindingTime=postBuild
socketAddress	SocketAddress	*	aggr	Collection of SoAdAddresses. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=socketAddress.shortName, socket Address.variationPoint.shortLabel vh.latestBindingTime=postBuild

Table 6.118: SoAdConfig

The SocketAddress is the element that is used to establish the link between the EcuInstance and the NetworkEndpoint. The SocketAddress has a connector reference to the EthernetCommunicationConnector. The SocketAddress also aggregates the ApplicationEndpoint that in turn references the NetworkEndpoint.

Class	SocketAddress			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	This meta-class represents a socket address towards the rest of the meta-model. The actual semantics of the represented socket address, however, is contributed by aggregation of an ApplicationEndpoint.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SoAdConfig.socketAddress			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
allowedIPv6Ext Headers	IPv6ExtHeaderFilterList	0..1	ref	Reference to a list of IPv6 Extension Headers allowed for this SocketConnection. If no list is referenced all IPv6 Extension Headers are allowed and processed.
allowedTcp Options	TcpOptionFilterList	0..1	ref	Reference to a list of TCP options allowed for this Socket Connection.
application Endpoint	ApplicationEndpoint	0..1	aggr	Application addressing
connector	EthernetCommunication Connector	0..1	ref	Association to a CommunicationConnector in the topology description. This reference shall be used if the SocketAddress describes an IP unicast address for an ECU that is part of the model.
differentiated ServiceField	PositiveInteger	0..1	attr	The 6-bit Differentiated Service Field in the IP headers may be used for classifying network traffic. If not set a value of zero is used to indicate packets that have not been classified.
flowLabel	PositiveInteger	0..1	attr	The 20-bit Flow Label field in the IPv6 header may be used by a source to label sequences of packets for which it requests special handling by the IPv6 routers, such as non-default quality of service. If not set a Flow Label of zero is used to indicate packets that have not been labeled.

▽

△

Class	SocketAddress			
multicast Connector	EthernetCommunication Connector	*	ref	Association to a CommunicationConnector in the topology description. This reference shall be used if the SocketAddress describes an IP multicast address, i.e. if the aggregated ApplicationEndpoint references a NetworkEndpoint that describes an IP Address in the IP multicast range. Such a SocketAddress contains references to those Ecus (via the multicastConnector reference) in the model that will receive multicast messages via the SocketAddress that is defined by the aggregated ApplicationEndpoint and NetworkEndpoint, i.e. IP Address and UDP Port combination. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=multicastConnector
pathMtu Discovery Enabled	Boolean	0..1	attr	Defines whether the Path MTU Discovery shall be performed for the related socket.
pduCollection MaxBufferSize	PositiveInteger	0..1	attr	Defines the maximum buffer size in Byte which shall be filled before a socket with Pdu collection enabled shall be transmitted to the lower layer.
pduCollection Timeout	TimeValue	0..1	attr	Defines the time in seconds which shall pass before a socket with Pdu collection enabled shall be transmitted to the lower layer after the first Pdu has been put into the socket buffer.
staticSocket Connection	StaticSocketConnection	*	aggr	Definition of a static SocketConnection. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=staticSocketConnection.shortName, staticSocketConnection.variationPoint.shortLabel vh.latestBindingTime=postBuild
ttl	PositiveInteger	0..1	attr	This attribute defines a value set in the header of an Internet Protocol (IP) packet that tells network devices the maximum number of router hops the packet can make before it is discarded. The TTL value is a counter that is decremented by 1 every time the packet passes through a router.
udpChecksum Handling	UdpChecksum CalculationEnum	0..1	attr	Specifies if UDP checksum handling shall be enabled (udpChecksumEnabled) or skipped (udpChecksumDisabled) on the related socket connection.

Table 6.119: SocketAddress

The communication endpoint itself is defined by the `ApplicationEndpoint` that is aggregated by the `SocketAddress` and by the `NetworkEndpoint` that in turn is referenced by the `ApplicationEndpoint` and is defined on the VLAN. The `ApplicationEndpoint` is the endpoint in terms of application addressing and defines the transport layer configuration. The IP-address that is connected to the transport layer is defined by the referenced `NetworkEndpoint`.

[constr_5061] `EthernetCommunicationConnector`s and referencing `SocketAddress`es shall be in the same VLAN

Imposition time: `IT_SysDesc`

⌈Each `EthernetCommunicationConnector` that is referenced by a `SocketAddress` in the role `connector` or `multicastConnector` shall be referenced by the same EthernetPhysicalChannel that aggregates the SoAdConfig that in turn aggregates the SocketAddress.⌋

[constr_5326] Each local SocketAddress of an EcuInstance shall reference an EthernetCommunicationConnector in the role connector or multicastConnector

Imposition time: IT_SysDesc

⌈If an EcuInstance uses a SocketAddress as local address, the SocketAddress shall refer to an EthernetCommunicationConnector of the EcuInstance, either via SocketAddress.connector if the SocketAddress represents a unicast address, or via SocketAddress.multicastConnector if the SocketAddress represents a multicast address.⌋

[constr_3299] SocketAddress.pathMtuDiscoveryEnabled setting dependency

Imposition time: IT_SysDesc

⌈SocketAddress.pathMtuDiscoveryEnabled shall only be set to TRUE if EthernetCommunicationConnector.pathMtuEnabled == TRUE.⌋

[constr_3311] Usage of SocketAddress.flowLabel

Imposition time: IT_SysDesc

⌈SocketAddress.flowLabel shall only be used if the aggregated ApplicationEndpoint refers to a NetworkEndpoint with an Ipv6Configuration.⌋

[TPS_SYST_02140] SocketAddress.udpChecksumHandling default value ⌈If SocketAddress.udpChecksumHandling is not used the value udpChecksumEnabled shall be assumed.⌋

Enumeration	**UdpChecksumCalculationEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances
Note	This enumeration defines the UDP checksum calculation.
Aggregated by	SocketAddress.udpChecksumHandling, SocketConnectionBundle.udpChecksumHandling
Literal	***Description***
udpChecksum Disabled	Udp checksum handling shall be disabled **Tags:** atp.EnumerationLiteralIndex=1
udpChecksum Enabled	Udp checksum handling shall be enabled **Tags:** atp.EnumerationLiteralIndex=0

Table 6.120: UdpChecksumCalculationEnum

[TPS_SYST_02141] Semantics of udpChecksumHandling ⌈The semantics of udpChecksumHandling is different for the sending and the receiving side:

TX - calculation of UDP checksum:

- udpChecksumEnabled means that the UDP checksum is calculated on the transmission side.
- udpChecksumDisabled means that the UDP checksum is not calculated but set to zero on the transmission side.

RX - handling of UDP checksum of zero:

- udpChecksumEnabled means that the UDP checksum of zero is treated as invalid checksum on receiver side (causing the UDP datagram to be dropped by the receiver). A valid non-zero checksum is accepted and the UDP datagram is forwarded to the upper layer.
- udpChecksumDisabled means the UDP checksum of zero is treated as valid checksum on the receiver side (causing the UDP datagram to be forwarded to the upper layer). A valid non-zero checksum is accepted and the UDP datagram is forwarded to the upper layer as well.

⌋

[TPS_SYST_02142] Reception of invalid checksum ⌈On Rx side an invalid checksum should always cause the related UDP datagram to be discarded independent of the udpChecksumHandling value.⌋

To enable the IPv6 packet filtering the attribute allowedIPv6ExtHeaders allows to define a permitted list of IPv6 Extension Headers that are allowed for a SocketAddress. Lists of IPv6 Extension Headers can be defined with the IPv6ExtHeaderFilterList element and can be collected in IPv6ExtHeaderFilterSets.

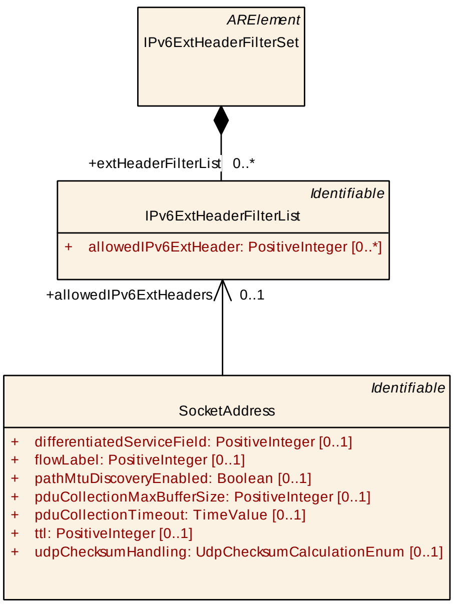

Figure 6.41: IPv6 Extension Header Filter Set

6.7.5.2 NetworkEndpoint

Class	**NetworkEndpoint**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	The network endpoint defines the network addressing (e.g. IP-Address or MAC multicast address).			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	EthernetPhysicalChannel.networkEndpoint			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
fullyQualified DomainName	String	0..1	attr	Defines the fully qualified domain name (FQDN) e.g. some.example.host.
infrastructure Services	InfrastructureServices	0..1	aggr	Defines the network infrastructure services provided or consumed.
ipSecConfig	IPSecConfig	0..1	aggr	Optional IPSec configuration that provides security services for IP packets.
network Endpoint Address	NetworkEndpoint Address	*	aggr	Definition of a Network Address. **Tags:** xml.name Plural=NETWORK-ENDPOINT-ADDRESSES
priority	PositiveInteger	0..1	attr	Defines the frame priority where values from 0 (best effort) to 7 (highest) are allowed.

Table 6.135: NetworkEndpoint

The NetworkEndpoint defines the network addressing. The network endpoint may have a priority and a FQDN (Fully Qualified Domain Name) that is used for the Service Discovery (e.g. some.example.host.).

[constr_9122] Existence of NetworkEndpoint.networkEndpointAddress

Imposition time: IT_SysDesc

⌈For each NetworkEndpoint, the aggregation of NetworkEndpointAddress in the role networkEndpointAddress shall exist.⌋

[TPS_SYST_01090] valid NetworkEndpoint

Upstream requirements: RS_SYST_00039

⌈To build a valid NetworkEndpoint at least one of the following options shall be defined in the role NetworkEndpoint.networkEndpointAddress:

- a MacMulticastConfiguration with a reference to a MacMulticastGroup
- Ipv4Configuration
- Ipv6Configuration

⌋

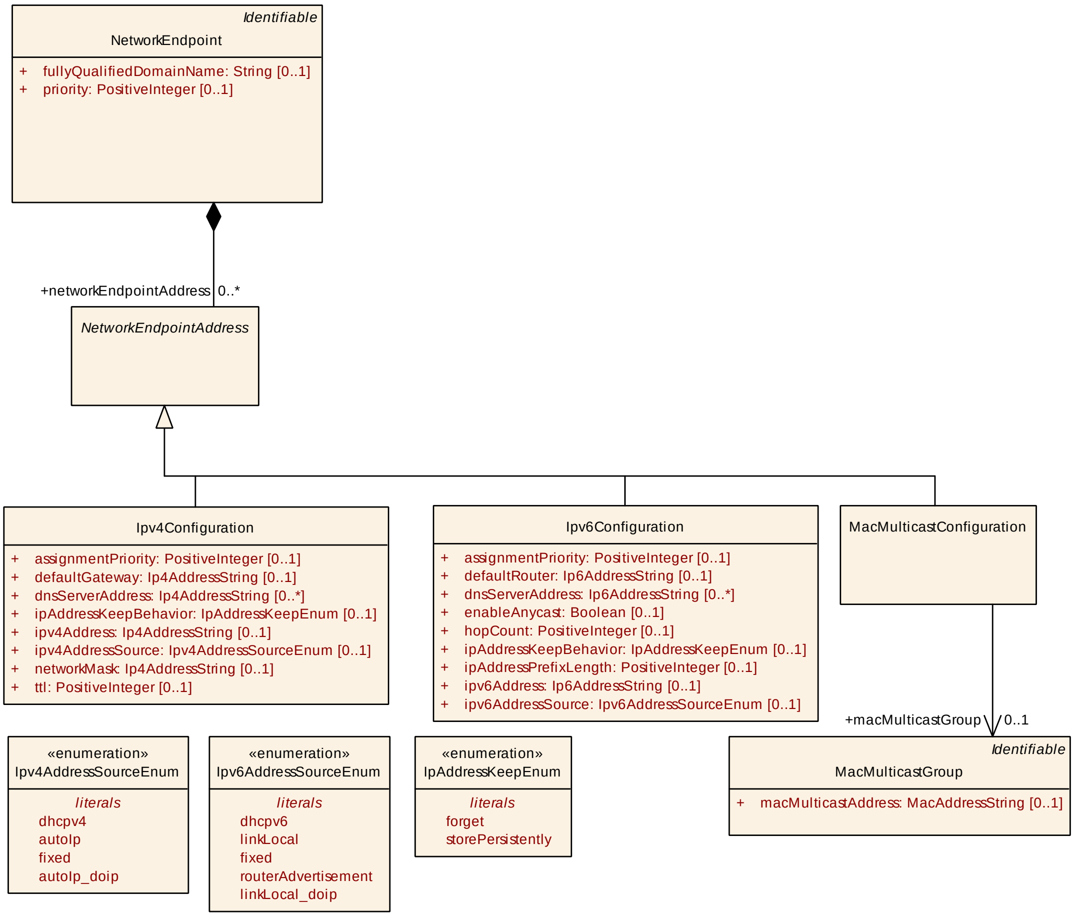

Figure 6.44: Network Endpoint

The attribute NetworkEndpoint.networkEndpointAddress defines whether an **IPv4**, **IPv6** or **MAC multicast** address is assigned to the NetworkEndpoint.

The reference of the MacMulticastConfiguration.macMulticastGroup defines the mapping of IP multicast to MAC multicast.

[TPS_SYST_01088] `NetworkEndpoint` priority

Upstream requirements: RS_SYST_00039

⌈The `priority` at the `NetworkEndpoint` shall be used as Ethernet Header information together with the `vlanIdentifier`. If defined the `priority` overwrites the `defaultPriority` that is defined in the `VlanMembership`.⌋

Class	***NetworkEndpointAddress*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::EthernetTopology			
Note	To build a valid network endpoint address there has to be either one MAC multicast group reference or an ipv4 configuration or an ipv6 configuration.			
Base	*ARObject*			
Subclasses	Ipv4Configuration, Ipv6Configuration, MacMulticastConfiguration			
Aggregated by	NetworkEndpoint.networkEndpointAddress			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
–	–	–	–	–

Table 6.136: NetworkEndpointAddress

Class	**Ipv4Configuration**

6.7.5.3 Service Instances

The AUTOSAR protocol Service Discovery protocol is used to communicate the availability of functional entities called services in the in-vehicle communication and to control the send behavior of event messages to receivers that subscribed to receive these events (Publish/Subscribe). A Service may also provide methods that a client is able to call (Request/Response).

Please note that the AUTOSAR Classic Platform does not support Service Interfaces. To mimic a Service Interface in the classic platform any combination of ClientServerInterfaces, SenderReceiverInterfaces or TriggerInterfaces may be used to describe a service to which later a Service Id is assigned.

The assignment of Service Ids is done on the Service Instance level in the System Description. An AbstractServiceInstance collected in the ServiceInstanceCollectionSet is describing such a Service Instance.

Class	ServiceInstanceCollectionSet

majorVersion	PositiveInteger	0..1	attr	Major Version of the ServiceInterface. Value can be set to a number that represents the Major Version of the service.
methodActivationRoutingGroup	PduActivationRoutingGroup	0..1	aggr	The ServiceDiscovery module is able to activate and deactivate the PDU routing for ClientServerOperations (SOME/IP methods). **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=methodActivationRoutingGroup.shortName, methodActivationRoutingGroup.variationPoint.shortLabel vh.latestBindingTime=postBuild
routingGroup	SoAdRoutingGroup	*	ref	The ServiceDiscovery module is able to activate and deactivate the PDU routing from and to TCP/IP-sockets. **Tags:** atp.Status=obsolete

Table 6.159: AbstractServiceInstance

It is possible to specify additional information about the `AbstractServiceInstance` with the Capability Record that allows to transport arbitrary configuration strings (key/-value pairs). This allows to encode additional information like the name of a service or its configuration.

[TPS_SYST_02216] Configuration of capabilityRecords ⌈A Capability Record (key/value pair) is configurable with the AbstractServiceInstance.capabilityRecord and the two attributes key and value.⌋

Class	TagWithOptionalValue			
Package	M2::AUTOSARTemplates::GenericStructure::GeneralTemplateClasses::TagWithOptionalValue			
Note	A tagged value is a combination of a tag (key) and a value that gives supplementary information that is attached to a model element. Please note that keys without a value are allowed.			
Base	*ARObject*			
Aggregated by	*AbstractServiceInstance*.capabilityRecord, Machine.environmentVariable, ProvidedSomeipServiceInstance.capabilityRecord, RequiredSomeipServiceInstance.capabilityRecord, SdClientConfig.capabilityRecord, SdServerConfig.capabilityRecord, StartupConfig.environmentVariable			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
key	String	0..1	attr	Defines a key.
sequenceOffset	Integer	0..1	attr	The sequenceOffset attribute supports the use case where TagWithOptionalValue is aggregated as splitable. If multiple aggregations define the same value of attribute key then the order in which the value collection is merged might be significant. As an example consider the modeling of the $PATH environment variable by means of a meta class TagWithOptionalValue. The sequenceOffset describes the relative position of each contribution in the concatenated value. The contributions are sorted in increasing integer order.
value	String	0..1	attr	Defines the corresponding value.

Table 6.160: TagWithOptionalValue

[TPS_SYST_01094] allowed key/value TagWithOptionalValue combinations

Upstream requirements: RS_SYST_00039

⌈The following key/value combinations are supported:

- key present, with no value (e.g. "passreq" -> password required for this service)
- key present, with empty value (e.g. "PlugIns=" -> server supports plugins, but none are presently installed)
- key present, with non-empty value (e.g. "PlugIns=JPEG,MPEG2,MPEG4")

⌋

6.7.5.3.1 SOME/IP Service Instances

A SOME/IP serialized message is represented by an ISignal that aggregates the SOMEIPTransformationISignalProps that in turn references the TransformationTechnology with the protocol set to SOMEIP. The ISignal is mapped into an ISignalIPdu and the PduTriggering that instantiates the ISignalIPdu on the VLAN is related to a ProvidedServiceInstance or ConsumedServiceInstance via a PduActivationRoutingGroup. The ProvidedServiceInstance.majorVersion or ConsumedServiceInstance.majorVersion describes the Service Interface Version that is transported in the Header of the SOME/IP message to identify the source of the message.

[TPS_SYST_02377] Consistent setting of Service Interface Version ⌈The Service Interface Version represented by the SOMEIPTransformation (either via SOMEIPTransformationISignalProps.interfaceVersion of the ISignal or via SOMEIPTransformationDescription.interfaceVersion of the TransformationTechnology that is referenced by the SOMEIPTransformationISignalProps of the ISignal) shall be equal to the corresponding ProvidedServiceInstance.majorVersion or ConsumedServiceInstance.majorVersion.⌋

The following chapters are describing the configuration of SOME/IP ProvidedServiceInstances and ConsumedServiceInstances in more detail. Please note that currently the communication between a ProvidedServiceInstance and a ConsumedServiceInstance is restricted to a VLAN (see also [constr_5079]).

Note: classes called ProvidedServiceInstances and ConsumedServiceInstances are specific for SOME/IP.

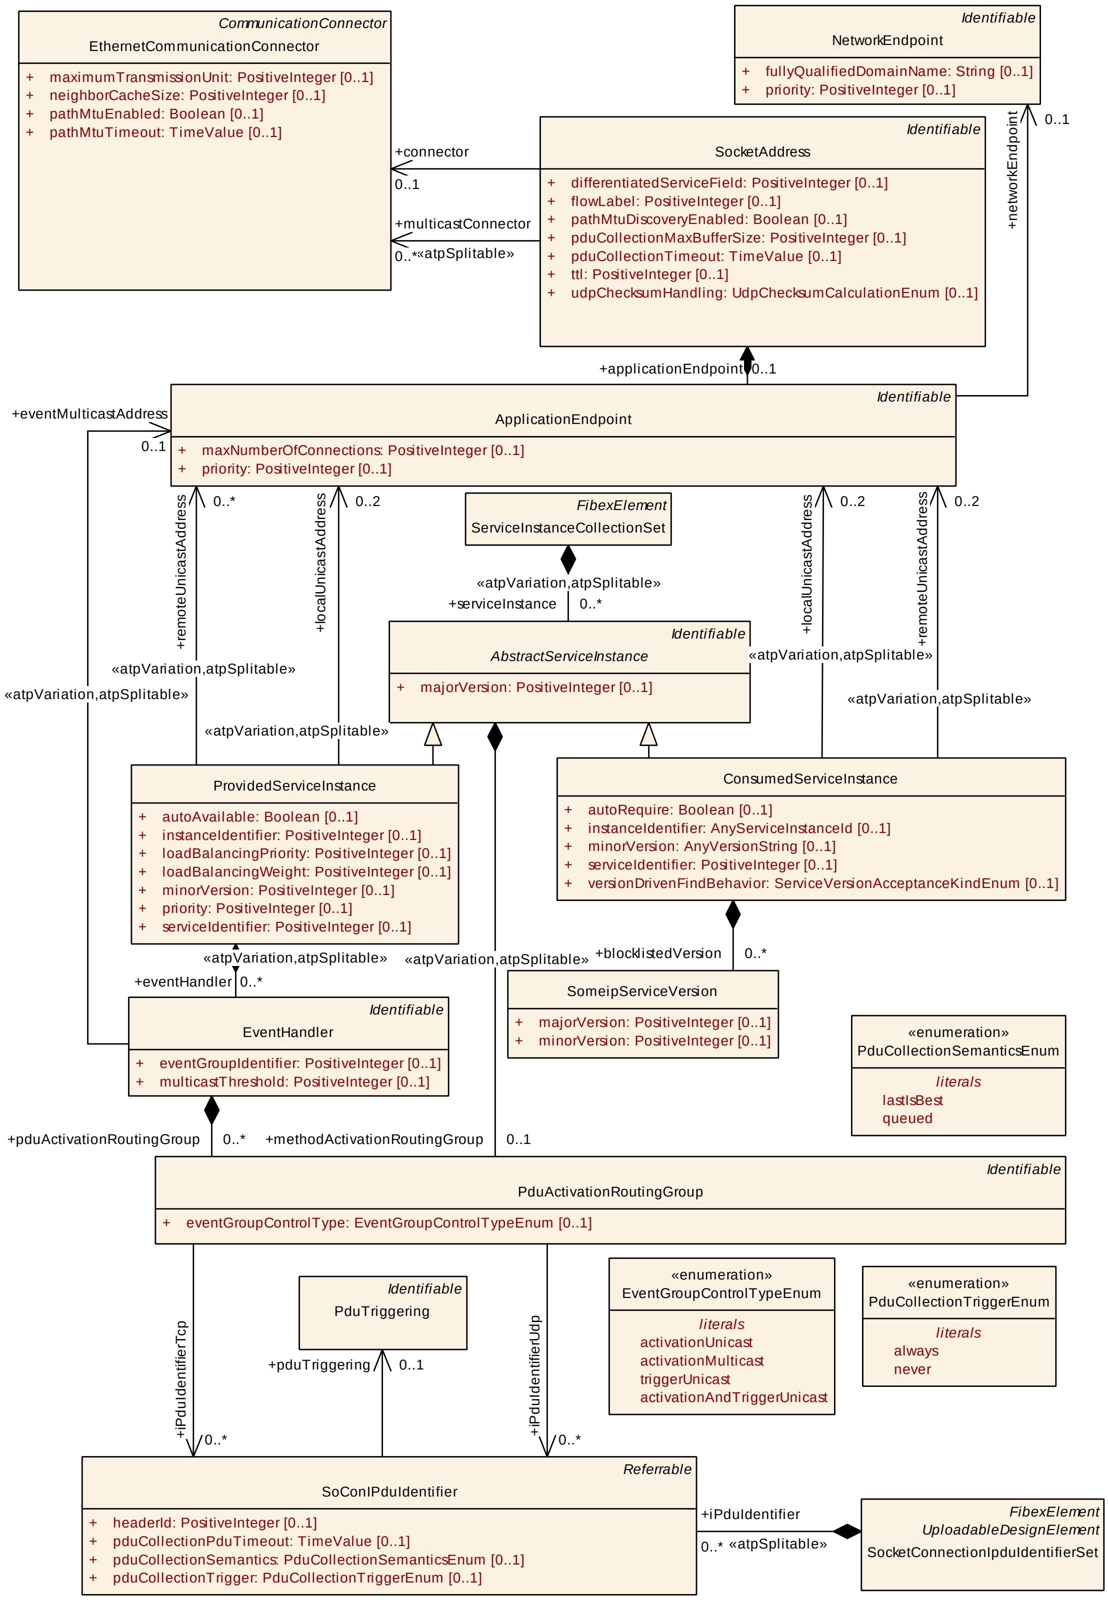

Figure 6.46: Provided and Consumed Service Instances

6.7.5.4 Multicast Subscription

The established approach for service subscription is that a client uses an *unicast* endpoint to subscribe to a server and the server acknowledges the subscription providing a *multicast* endpoint. The client has a *unicast* socket where the events are received in case the server distributes its events in *unicast* mode and the client has a *multicast* socket where the events are received in case the server switches to *multicast* sending (based on the multicastThreshold).

An extended approach is to allow a client to subscribe using a *multicast* endpoint (combination of multicast IP-Address and port). Thus, in the event group subscription a *multicast* endpoint is sent from the client to the server. The server handles this *multicast* endpoint as it would be an *unicast* endpoint. But the server collects identical *multicast* endpoints and handles them as ONE client.

The goal of this approach is to be able to have a group of clients subscribing to a common *multicast* endpoint, while other clients still are able to subscribe using a *unicast* endpoint.

This feature is called **multicast subscription**.

If, for example, THREE clients subscribe to an event group with the same *multicast* endpoint and ONE client subscribes with an *unicast* endpoint to the same event group, then the server would consider this as having TWO clients. The events of this event group will be sent every time once to the *multicast* endpoint (where it actually would be received by THREE clients) and once to the *unicast* endpoint for the *unicast* client.

Note that, in case PduActivationRoutingGroup.eventGroupControlType is defined as triggerUnicast or activationAndTriggerUnicast there will be an initial event sent every time another client subscribes using the same *multicast* endpoint. Thus, already subscribed clients on that *multicast* endpoint will get that initial event as well.

Even if further clients subscribe to the already used *multicast* endpoint the number of clients counted for the calculation of the multicastThreshold is not increased. In the sketched example there would still be TWO clients registered for subscription.

Of course, if further clients subscribe to the very same event group with different *multicast* or *unicast* endpoints, these additional clients are considered in the multicastThreshold count. Thus, at exceeding the multicastThreshold, count the server will switch to the one *multicast* endpoint which the server distributed to all of its clients in the subscribe acknowledge message. At this point ALL subscribed clients (regardless whether they subscribed using an *unicast* or *multicast* endpoint) will receive the events on the subscribe acknowledge *multicast* endpoint provided by the server.

The server keeps track of how many clients subscribed to a dedicated *multicast* endpoint.

In case of unsubscribe or expiration of a subscription which was subscribed using a *multicast* endpoint the server needs to decrement the count of subscriptions for that specific *multicast* endpoint. If the last subscriber unsubscribes the subscription to that *multicast* endpoint is removed.

Note that each *multicast* endpoint has an own subscription count to be kept by the server.

For details on the multicast subscription feature refer to the protocol specification [25] and functional specification [26].

Enabling the multicast subscription:

[TPS_SYST_03064] Enabling of multicast subscription ⌈The multicast subscription is enabled when a ConsumedServiceInstance defines a eventMulticastSubscriptionAddress reference to an ApplicationEndpoint.⌋

[constr_3669] eventMulticastSubscriptionAddress shall refer to a multicast address

Imposition time: IT_SysDesc

⌈The reference ConsumedServiceInstance.eventMulticastSubscriptionAddress shall refer to an ApplicationEndpoint which in turn refers to a NetworkEndpoint that represents a multicast address.⌋

If the multicast subscription is enabled for a client then it is not allowed to have also a unicast subscription defined.

[constr_3670] No support for parallel localUnicastAddress and eventMulticastSubscriptionAddress

Imposition time: IT_SysDesc

⌈If a eventMulticastSubscriptionAddress is defined for a ConsumedServiceInstance then there shall not be a localUnicastAddress defined at the same ConsumedServiceInstance.⌋

In case of a static configuration it is also possible to define a set of predefined *multicast* client endpoints at the server. This is supported also in a mixed configuration, where one part of the statically defined clients is defined using ProvidedServiceInstance.remoteUnicastAddress and the other part of the statically defined clients is defined using ProvidedServiceInstance.remoteMulticastSubscriptionAddress. The server takes the union of both sets as the set of statically defined clients.

[TPS_SYST_03065] Static definition of multicast subscription at the server ⌈The ProvidedServiceInstance.remoteMulticastSubscriptionAddress defines a set of remote multicast addresses which are handled by the server as predefined subscribed clients.⌋

[TPS_SYST_03066] Mix of static definition consisting of multicast subscription clients and unicast subscription clients at the server ⌈It is well supported to define both, a set of ProvidedServiceInstance.remoteUnicastAddress and a set of ProvidedServiceInstance.remoteMulticastSubscriptionAddress references. The server is then configured to handle the union of both sets as the predefined clients.⌋

[constr_3671] remoteMulticastSubscriptionAddress shall refer to a multicast address

Imposition time: IT_SysDesc

⌈The reference ProvidedServiceInstance.remoteMulticastSubscriptionAddress shall refer to an ApplicationEndpoint which in turn refers to a NetworkEndpoint that represents a multicast address.⌋

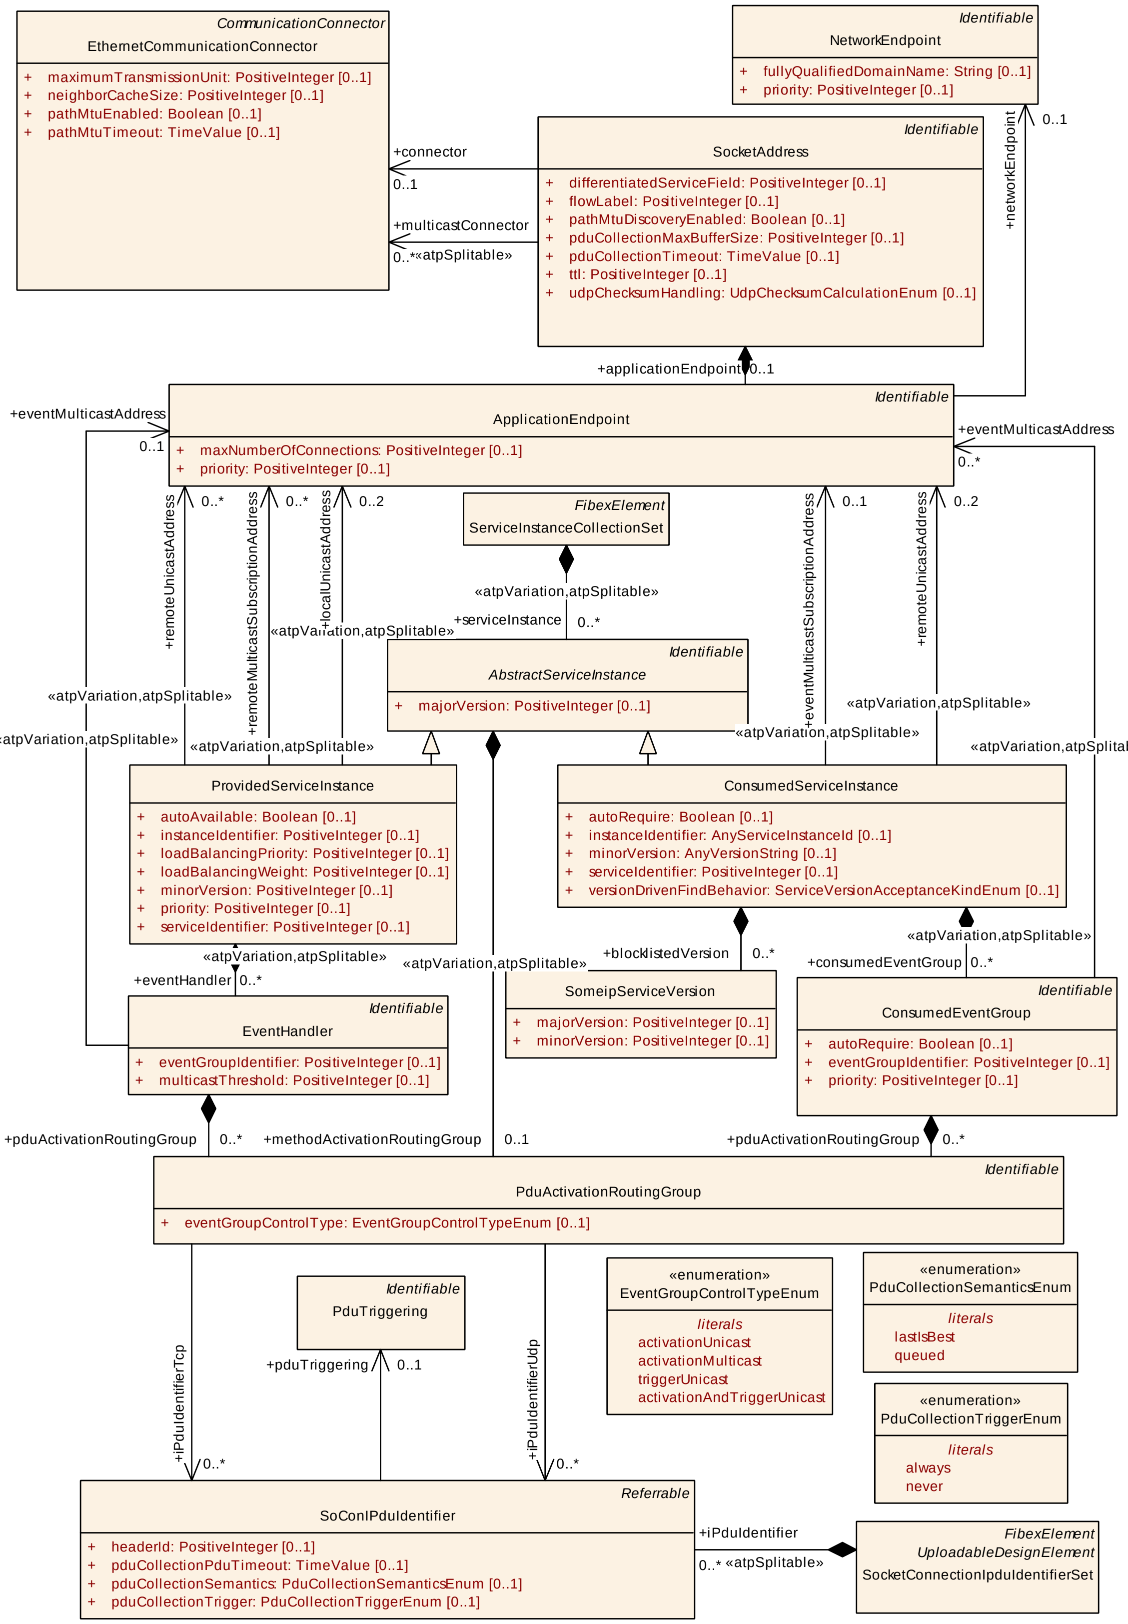

Figure 6.47: Multicast Subscribe

There are several constrains to be considered when using the `multicast subscription` feature:

If a ConsumedServiceInstance has methods defined, then the multicast subscription is not possible.

[constr_3672] No support for methods in multicast subscription at the client

Imposition time: IT_SysDesc

⌈If a ConsumedServiceInstance aggregates a PduActivationRoutingGroup in the role methodActivationRoutingGroup, then the ConsumedServiceInstance shall not define a eventMulticastSubscriptionAddress.⌋

A server is able to define a set of statically configured client addresses using the ProvidedServiceInstance.remoteMulticastSubscriptionAddress reference. But if the server also provides methods it is not possible to define static *multicast* receivers for that server.

[constr_3673] No support for methods in multicast subscription at the server static configuration

Imposition time: IT_SysDesc

⌈If a ProvidedServiceInstance aggregates a PduActivationRoutingGroup in the role methodActivationRoutingGroup, then the ProvidedServiceInstance.remoteMulticastSubscriptionAddress shall not be defined.⌋

There are some features of AUTOSAR which need to be carefully considered when used in combination with multicast subscription:

- communication which relies on sequence counting might not operate properly (e.g. E2E or SecOC) if initial events are sent on every subscription to an *multicast* endpoint
- communication which requires point-to-point interaction may not operate properly (e.g. IPSec or TLS)

6.7.5.5 SOME/IP specific description

6.7.5.5.1 SOME/IP ProvidedServiceInstance

The ProvidedServiceInstance is used to define a SOME/IP Service provider.

[TPS_SYST_02217] SOME/IP Service offer

Upstream requirements: RS_SYST_00039

⌈The EcuInstance on which the ProvidedServiceInstance is deployed offers the Service Instance over SOME/IP with the serviceIdentifier and instanceIdentifier. The version of the Service that is offered is described by the attributes majorVersion and minorVersion.⌋

[constr_5062] SOME/IP ProvidedServiceInstances of the same serviceInterface on one EcuInstance

Imposition time: IT_SysDesc

⌈Different ProvidedServiceInstances with the same serviceIdentifier and the same majorVersion and different instanceIdentifiers shall not be mapped to the same UDP/TCP port number and IP address combination that is represented by referenced ApplicationEndpoint and its referenced NetworkEndpoint.⌋

The reason for this restriction is that the Instance IDs are only used for Service Discovery but are not contained in the SOME/IP header. So if for example two ProvidedServiceInstances of the same ServiceInterface are provided on the same EcuInstance and a client wants to call a method of one of these ProvidedServiceInstances the only possibility for the client to distinguish the ProvidedServiceInstances is the port number over which the individual ProvidedServiceInstances are provided.

[constr_5063] ProvidedServiceInstance.serviceIdentifier is mandatory

Imposition time: IT_SysDesc

⌈The ProvidedServiceInstance.serviceIdentifier is mandatory.⌋

[constr_5064] ProvidedServiceInstance.majorVersion is mandatory

Imposition time: IT_SysDesc

⌈The ProvidedServiceInstance.majorVersion is mandatory.⌋

[constr_5065] ProvidedServiceInstance.minorVersion is mandatory

Imposition time: IT_SysDesc

⌈The ProvidedServiceInstance.minorVersion is mandatory.⌋

[constr_5066] ProvidedServiceInstance.instanceIdentifier is mandatory

Imposition time: IT_SysDesc

⌈The ProvidedServiceInstance.instanceIdentifier is mandatory.⌋

[constr_5067] ProvidedServiceInstance shall be unique in respect of serviceIdentifier, instanceIdentifier, majorVersion

Imposition time: IT_SysDesc

⌈On a VLAN each ProvidedServiceInstance shall have a different serviceIdentifier, instanceIdentifier and majorVersion value combination.⌋

The reason for this constraint is that the Service Discovery messages have to be unambiguous on the VLAN.

In other words no two ProvidedServiceInstances in a variant bound model shall have the same serviceIdentifier, instanceIdentifier and majorVersion value combination.

Class	**ProvidedServiceInstance**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances

autoAvailable	Boolean	0..1	attr	Defines that this ProvidedServiceInstance shall be offered by the service discovery at ECU start.
eventHandler	EventHandler	*	aggr	Collection of event groups provided by the Provided ServiceInstance **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=eventHandler.shortName, event Handler.variationPoint.shortLabel vh.latestBindingTime=postBuild
instance Identifier	PositiveInteger	0..1	attr	Instance identifier. Can be used for e.g. service discovery to identify the instance of the service.
loadBalancing Priority	PositiveInteger	0..1	attr	Defines the value to be used for load balancing priority in the service offer. Lower value means higher priority.
loadBalancing Weight	PositiveInteger	0..1	attr	Defines the value to be used for load balancing weight in the service offer. Higher value means higher probability to be chosen.

▽

△

Class	**ProvidedServiceInstance**			
localUnicast Address	ApplicationEndpoint	0..2	ref	The local address over which the PSI is provided (udp, tcp or both). **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=localUnicastAddress.applicationEndpoint, localUnicastAddress.variationPoint.shortLabel vh.latestBindingTime=postBuild
minorVersion	PositiveInteger	0..1	attr	Minor Version of the Service that is provided by this ProvidedServiceInstance.
priority	PositiveInteger	0..1	attr	Defines the frame priority where values from 0 (best effort) to 7 (highest) are allowed.
remoteMulticast Subscription Address	ApplicationEndpoint	*	ref	This reference defines the remote multicast subscribed addresses of service consumers. This reference shall ONLY be used if the remote address of the clients is determined from the configuration and not at runtime. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=remoteMulticastSubscription Address.applicationEndpoint, remoteMulticast SubscriptionAddress.variationPoint.shortLabel vh.latestBindingTime=postBuild
remoteUnicast Address	ApplicationEndpoint	*	ref	This reference defines the remote addresses of service consumers. This reference shall ONLY be used if the remote address of the clients is determined from the configuration and not at runtime. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=remoteUnicastAddress.applicationEndpoint, remoteUnicastAddress.variationPoint.shortLabel vh.latestBindingTime=postBuild
sdServerConfig	SdServerConfig	0..1	aggr	Service Discovery Server configuration. **Tags:** atp.Status=obsolete
sdServerTimer Config	SomeipSdServer ServiceInstanceConfig	0..1	ref	Server specific configuration settings relevant for the SOME/IP service discovery. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=sdServerTimerConfig.someipSdServer ServiceInstanceConfig, sdServerTimerConfig.variation Point.shortLabel vh.latestBindingTime=postBuild
serviceIdentifier	PositiveInteger	0..1	attr	This attribute represents the ability to describe the SOME/IP service ID that is offered.

Table 6.161: ProvidedServiceInstance

[TPS_SYST_02218] ProvidedServiceInstance deployment

Upstream requirements: RS_SYST_00039

⌈The deployment of a ProvidedServiceInstance to an EcuInstance is realized with the localUnicastAddress reference. The referenced ApplicationEndpoint defines the TCP/UDP Port and the NetworkEndpoint that is referenced by the ApplicationEndpoint defines the IP Address on which the Service can be reached. This Endpoint information is transported in the SOME/IP Service Offer message to the clients. With the SocketAddress.connector reference the deployment to an EcuInstance is achieved.⌋

The AUTOSAR BswM is used to aggregate the availability of all entities which make up a service instance. When all entities are available, the service instance as such is available. When a service instance becomes available the SD Module will usually send an announcement message so other ECUs can learn about the availability and the location (IP address and UDP or TCP Port) of that service instance.

Please note that the Service provider and the Service consumer do not need to find each other if the ProvidedServiceInstance contains a remoteUnicastAddress reference to an ApplicationEndpoint. If this reference is set, the Server will not get the client's address from the connection request.

The server knows the address of the Client from the configuration and all necessary socket connections can be set up from this configuration information. The client still needs to subscribe to event groups that are of interest for it in this setup.

[TPS_SYST_02219] Static configuration between ProvidedServiceInstance and ConsumedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ProvidedServiceInstance contains a remoteUnicastAddress reference to an ApplicationEndpoint the SoAd will setup one single SocketConnection between the localUnicastAddress and the remoteUnicastAddress.⌋

[TPS_SYST_02220] Maximal number of clients that may connect to the local server address

Upstream requirements: RS_SYST_00039

⌈If the ProvidedServiceInstance references an ApplicationEndpoint in the role localUnicastAddress then the attribute ApplicationEndpoint.maxNumberOfConnections defines the maximal number of clients (with a dynamic address) that will be able to connect to this local server address. The SoAd will setup a SocketConnection for each potential client with localUnicastAddress and ANY remote Address (ANY Port and ANY IP-Address).⌋

[constr_5068] ProvidedServiceInstance.localUnicastAddress shall be IP Unicast

Imposition time: IT_SysDesc

⌈If defined, the ProvidedServiceInstance.localUnicastAddress shall point to an IP Unicast address.⌋

[constr_5069] ProvidedServiceInstance.remoteUnicastAddress shall be IP Unicast

Imposition time: IT_SysDesc

⌈The ProvidedServiceInstance.remoteUnicastAddress shall point to an IP Unicast address.⌋

In other words the localUnicastAddress and remoteUnicastAddress are not allowed to point to an IP Multicast address. Please note that an IP Unicast address can be defined as a fixed address or be retrieved via dynamic mechanisms, e.g. DHCP.

Please note that a Service may provide some portions (Events, Methods) over TCP and other portions over UDP. This is the reason why the ProvidedServiceInstance is able to reference up to two localUnicastAddresses.

[TPS_SYST_02221] ProvidedServiceInstance.localUnicastAddress reference target

Upstream requirements: RS_SYST_00039

⌈The ProvidedServiceInstance is allowed to have:

- a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP Port,
- a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP Port,
- a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP Port and a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP Port.

⌋

[constr_3379] Multiple SocketAddress entries with the same IP Address, Protocol and Port in the context of a given EcuInstance

Imposition time: IT_SysDesc

⌈If there are two or more SocketAddress entities within the scope of one SoAdConfig in the scope of one EcuInstance that have the same static (fixed at configuration time) IP Address, Protocol and Port in the aggregated ApplicationEndpoint and NetworkEndpoint, (e.g., 192.168.1.1, Tcp and 10000, respectively) then only one of these SocketAddress elements shall be referenced by ProvidedServiceInstances/ConsumedServiceInstances in the role localUnicastAddress.⌋

Rationale for [constr_3379]: There can be only one representation of the ProvidedServiceInstance/ConsumedServiceInstance using the given IP Address, Protocol and Port in the Sd module configuration in the context of a given EcuInstance. Therefore, defining ProvidedServiceInstance/ConsumedServiceInstance and assign it to several ApplicationEndpoints would in this case require a merge of potentially different attribute values of the ProvidedServiceInstances and/or ConsumedServiceInstances in the System Description and such situation is avoided by this constraint.

Class	**PduActivationRoutingGroup**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	Group of Pdus that can be activated or deactivated for transmission over a socket connection.

lastIsBest	Only the latest PDU instances are transmitted. **Tags:** atp.EnumerationLiteralIndex=0
queued	All instances of PDUs are transmitted. **Tags:** atp.EnumerationLiteralIndex=1

Table 6.166: PduCollectionSemanticsEnum

[TPS_SYST_02222] Usage of headerId

Upstream requirements: RS_SYST_00039

⌈If multiple SoConIPduIdentifiers are referenced by PduActivationRoutingGroup in the role iPduIdentifierTcp or in the role iPduIdentifierUdp then the headerId information shall be used to distinguish between the different Pdus.⌋

Please note that a Method Call and a Method Return may use the same headerId for identification since the communication direction is different in this case.

[constr_3322] Consistent setting of SoConIPduIdentifier.pduCollectionSemantics in the context of one SocketAddress

Imposition time: IT_SysDesc

⌈The value of the attribute SoConIPduIdentifier.pduCollectionSemantics shall be identical for all referenced SoConIPduIdentifiers within the context of a given SocketAddress.⌋

[TPS_SYST_02223] Activation/Deactivation of PduActivationRoutingGroups

Upstream requirements: RS_SYST_00039

⌈The routing of Pdus to and from a socket may be activated or deactivated with a PduActivationRoutingGroup depending on the availability of AbstractServiceInstances, EventHandlers or ConsumedEventGroups that send or receive the data.⌋

The Routing Group Activation Table is controlled in AUTOSAR by the Service Discovery module.

[TPS_SYST_02224] Methods provided by a ProvidedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ProvidedServiceInstance is offered by the Service Discovery protocol then the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup is activated. All Methods that are provided by the ProvidedServiceInstance can by called by the interested clients and the server will respond to these calls. If the ProvidedServiceInstance offer is stopped then the PduActivationRoutingGroup is deactivated.⌋

Please note that according to [TPS_SYST_02151] the relationship between the call and return is achieved by means of meta data items attached to the Pdus by the Socket Adapter.

[TPS_SYST_02081] PduTriggering that is used for ClientServer Communication ⌈A PduTriggering that points to an ISignalIPdu that aggregates an ISignalToIPduMapping that in turn references an ISignal that refers to a ClientServerToSignalMapping.callSignal or to ClientServerToSignalMapping.returnSignal is designated as PduTriggering that is used for ClientServer Communication.⌋

[TPS_SYST_02225] Service methods provided over UDP

Upstream requirements: RS_SYST_00039

⌈Method Pdus (Call and Return ISignalIPdus) of a ProvidedServiceInstance that are offered for access over UDP are described by SoConIPduIdentifiers referenced by the iPduIdentifierUdp reference from the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup by the ProvidedServiceInstance.⌋

[TPS_SYST_02226] Service methods provided over TCP

Upstream requirements: RS_SYST_00039

⌈Method Pdus (Call and Return ISignalIPdus) of a ProvidedServiceInstance that are offered for access over TCP are described by SoConIPduIdentifiers referenced by the iPduIdentifierTcp reference from the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup by the ProvidedServiceInstance.⌋

[TPS_SYST_02227] Publishing of a SOME/IP Event group

Upstream requirements: RS_SYST_00039

⌈A ProvidedServiceInstance publishes an event group for each EventHandler that is aggregated in the role eventHandler. The eventGroupIdentifier identifies the SOME/IP Event Group in the context of the ProvidedServiceInstance. With the publishing of an event group the server offers to push notifications about updates to all clients that are subscribed to the event group.⌋

Class	**EventHandler**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	This element represents an event group as part of the Provided Service Instance.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	ProvidedServiceInstance.eventHandler			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
consumedEventGroup	ConsumedEventGroup	*	ref	All consumers of the event are referenced here. **Tags:** atp.Status=obsolete
eventGroupIdentifier	PositiveInteger	0..1	attr	Unique Identifier that identifies the EventGroup in SOME/IP. This Identifier is sent as Eventgroup ID in SOME/IP Service Discovery messages.

▽

△

Class	EventHandler			
eventMulticast Address	ApplicationEndpoint	0..1	ref	Multicast Address that is used for event communication in the IP-Multicast case. It is the destination address to which the server sends the multicast event messages if the mulicastThreshold is exceeded. This address is transmitted in the SD-SubscribeEvent GroupAck Message to client (answer to SD-Subscribe EventGroup). **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=eventMulticastAddress.applicationEndpoint, eventMulticastAddress.variationPoint.shortLabel vh.latestBindingTime=postBuild
multicast Threshold	PositiveInteger	0..1	attr	Specifies the number of subscribed clients that trigger the server to change the transmission of events to multicast. If configured to 0 only unicast will be used. If configured to 1 the first client will be already served by multicast. If configured to 2 the first client will be server with unicast and as soon as the second client arrives both will be served by multicast. This does not influence the handling of initial events, which are served using unicast only.
pduActivation RoutingGroup	PduActivationRouting Group	*	aggr	The ServiceDiscovery module is able to activate and deactivate the PDU routing for events.
routingGroup	SoAdRoutingGroup	*	ref	The ServiceDiscovery module is able to activate and deactivate the PDU routing for events. **Tags:** atp.Status=obsolete
sdServerConfig	SdServerConfig	0..1	aggr	Server configuration parameter for Service-Discovery. **Tags:** atp.Status=obsolete
sdServerEg TimingConfig	SomeipSdServerEvent GroupTimingConfig	0..1	ref	Server Timing configuration settings that are EventGroup specific. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=sdServerEgTimingConfig.someipSdServer EventGroupTimingConfig, sdServerEgTiming Config.variationPoint.shortLabel vh.latestBindingTime=postBuild

Table 6.167: EventHandler

[TPS_SYST_02228] Transmission of events over UDP/TCP Port

Upstream requirements: RS_SYST_00039

⌈The events of an event group that are described by an `EventHandler` are transmitted either:

- via IP Unicast on the UDP/TCP Port that is defined by the `ApplicationEndpoint` that is referenced by the `ProvidedServiceInstance` in the role `localUnicastAddress` if the `eventMulticastAddress` is not set or the `multicastThreshold` is not reached, or
- via IP Multicast on the local UDP Port that is defined by the `ApplicationEndpoint` that is referenced by the `ProvidedServiceInstance` in the role `localUnicastAddress` to the IP Multicast remote Address that is defined by the

ApplicationEndpoint that is referenced by the EventHandler in the role eventMulticastAddress if the multicastThreshold is reached.

⌋

[constr_5331] No IP multicast in case of TCP

Imposition time: IT_SysDesc

⌈The ApplicationEndpoint that is referenced in the role eventMulticastAddress from an EventHandler is only allowed to aggregate UdpTp in the role tpConfiguration.⌋

[TPS_SYST_02180] Usage of EventHandler.multicastThreshold ⌈The switching between IP-Unicast and IP-Multicast is guided by the server with the EventHandler.multicastThreshold attribute and by the number of subscribed clients to the EventHandler.

The Server will change the transmission of events to Multicast if the multicastThreshold of the corresponding EventHandler is reached by the number of subscribed clients. If the number of subscribed clients is smaller then the configured multicastThreshold, the transmission of events takes place via unicast communication.⌋

[constr_5380] Assignment of the same event Pdu to several EventHandlers is forbidden in case one of the EventHandlers has the multicastThreshold set to a value greater than 0 in the context of an EcuInstance

Imposition time: IT_SysDesc

⌈SoConIPduIdentifiers with the same headerId shall not be referenced by PduActivationRoutingGroups of different EventHandlers if

- one or several of these EventHandlers has the multicastThreshold set to a value>0 and
- all these EventHandlers are aggregated by ProvidedServiceInstances that reference ApplicationEndpoints with the localUnicastAddress reference that in turn are aggregated by SocketAddresses which contain a reference to the same EthernetCommunicationConnector in the role connector (i.e. the EventHandlers are located on the same EcuInstance).

except for the case that all these EventHandlers have the multicastThreshold set to the value 1.⌋

[constr_5380] is introduced to forbid scenarios on an EcuInstance in which the Service Provider is forced to transmit the same event over IP Unicast and IP Multicast in cases where the same event is assigned to several EventHandlers (EventGroups) and the multicastThreshold is reached for one EventHandler, but not for the other ones.

[constr_5071] EventHandler.eventMulticastAddress reference target

Imposition time: IT_SysDesc

⌈The ApplicationEndpoint that is referenced by an EventHandler in the role eventMulticastAddress shall reference a NetworkEndpoint that defines an IP Multicast Address.⌋

[constr_5072] EventHandler without defined eventMulticastAddress

Imposition time: IT_SysDesc

⌈If an EventHandler that is aggregated by a ProvidedServiceInstance does not have a defined eventMulticastAddress then the multicastThreshold shall be set to the value 0 (IP Unicast only).⌋

[TPS_SYST_02229] Event groups provided by a ProvidedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ProvidedServiceInstance publishes an event group then the PduActivationRoutingGroup that is aggregated in the role pduActivationRoutingGroup by an EventHandler is activated. The interested clients can subscribe to the published event groups until the offer is stopped.⌋

[TPS_SYST_02230] PduActivationRoutingGroups for event groups ⌈The PduActivationRoutingGroup that is aggregated by the EventHandler in the role pduActivationRoutingGroup enables the routing of a group of Pdus that are related with the PduActivationRoutingGroup via the referenced SoConIPduIdentifiers.

- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationUnicast enables the routing over IP Unicast.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationMulticast enables the routing over IP Multicast.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to triggerUnicast enables the routing of initial events that are sent out by the server immediately after a client got subscribed. This PduActivationRoutingGroup can used for SOME/IP Field notifiers.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationAndTriggerUnicast enables the routing over IP Unicast and makes sure that initial events are sent

out by the server immediately after a client got subscribed. This PduActivationRoutingGroup can be used for SOME/IP Field notifiers.

⌋

[TPS_SYST_02231] PduActivationRoutingGroups for methods ⌈The PduActivationRoutingGroup enables the routing of a group of Pdus that are related with the PduActivationRoutingGroup via the referenced SoConIPduIdentifiers. The eventGroupControlType attribute is irrelevant for the PduActivationRoutingGroup that is aggregated by the AbstractServiceInstance in the role methodActivationRoutingGroup.⌋

[constr_5073] PduActivationRoutingGroup with eventGroupControlType set to activationUnicast or triggerUnicast or activationAndTriggerUnicast that is aggregated by an EventHandler

Imposition time: IT_SysDesc

⌈An EventHandler that aggregates a PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationUnicast or triggerUnicast or activationAndTriggerUnicast shall be aggregated by a ProvidedServiceInstance that has a localUnicastAddress reference that points to an IP Unicast Address.⌋

[constr_5074] PduActivationRoutingGroup with eventGroupControlType set to activationMulticast that is aggregated by an EventHandler

Imposition time: IT_SysDesc

⌈An EventHandler that aggregates a PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationMulticast shall have an eventMulticastAddress reference that points to a “remote” IP Multicast Address. The ProvidedServiceInstance that aggregates the EventHandler shall have a localUnicastAddress reference to a “local” UDP ApplicationEndpoint.⌋

[constr_5075] Allowed references of SoConIPduIdentifiers by PduActivationRoutingGroup with eventGroupControlType set to activationMulticast and allowed SoConIPduIdentifier references

Imposition time: IT_SysDesc

⌈A PduActivationRoutingGroup with eventGroupControlType set to activationMulticast is allowed to reference SoConIPduIdentifiers only in the iPduIdentifierUdp role.⌋

[TPS_SYST_02232] Events provided over UDP

Upstream requirements: RS_SYST_00039

⌈Pdus of an EventHandler that are provided over UDP are described by SoConIPduIdentifiers referenced by the iPduIdentifierUdp reference from the PduActivationRoutingGroup that is aggregated in the role pduActivationRoutingGroup by the EventHandler.⌋

[TPS_SYST_02233] Events provided over TCP

Upstream requirements: RS_SYST_00039

⌈Pdus of an EventHandler that are provided over TCP are described by SoConIPduIdentifiers referenced by the iPduIdentifierTcp reference from the PduActivationRoutingGroup that is aggregated in the role pduActivationRoutingGroup by the EventHandler.⌋

[constr_5076] PduActivationRoutingGroup with iPduIdentifierTcp reference that is aggregated by a ProvidedServiceInstance

Imposition time: IT_SysDesc

⌈If the PduActivationRoutingGroup contains the iPduIdentifierTcp reference then the aggregating ProvidedServiceInstance shall contain a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP address.⌋

[constr_5077] PduActivationRoutingGroup with iPduIdentifierUdp reference that is aggregated by a ProvidedServiceInstance

Imposition time: IT_SysDesc

⌈If the PduActivationRoutingGroup contains the iPduIdentifierUdp reference then the aggregating ProvidedServiceInstance shall contain a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP address.⌋

[constr_5078] PduTriggerings referenced by a PduActivationRoutingGroup shall be on the same VLAN as the referencing PduActivationRoutingGroup

Imposition time: IT_SysDesc

⌈Each PduTriggering referenced by a PduActivationRoutingGroup via SoConIPduIdentifier shall be aggregated by the same VLAN (EthernetPhysicalChannel) to which the AbstractServiceInstance that aggregates the PduActivationRoutingGroup belongs via the localUnicastAddress.⌋

[constr_5079] Service communication is restricted to one VLAN

Imposition time: IT_SysDesc

⌈All SocketAddress elements that are referenced by a AbstractServiceInstance with the localUnicastAddress and remoteUnicastAddress shall belong to the same VLAN (EthernetPhysicalChannel).⌋

[constr_5080] ApplicationEndpoints referenced by EventHandlers and by the aggregating ProvidedServiceInstance shall be in the same VLAN

Imposition time: IT_SysDesc

⌈The ApplicationEndpoint that is referenced by an EventHandler in the role eventMulticastAddress shall belong to the same VLAN (EthernetPhysicalChannel) as the ApplicationEndpoint that is referenced by the localUnicastAddress reference from the ProvidedServiceInstance that aggregates the EventHandler.⌋

[constr_3456] Existence of ProvidedServiceInstance.loadBalancingPriority and ProvidedServiceInstance.loadBalancingWeight

Imposition time: IT_SysDesc

⌈The attributes ProvidedServiceInstance.loadBalancingPriority and ProvidedServiceInstance.loadBalancingWeight shall either not exist or be defined both.⌋

[TPS_SYST_01108] ProvidedServiceInstance priority

Upstream requirements: RS_SYST_00039

⌈The priority in the ProvidedServiceInstance shall be used as Ethernet Header information together with the vlanIdentifier. If defined the priority overwrites the defaultPriority that is defined in the VlanMembership, the priority that is defined at the NetworkEndpoint and the priority that is defined at the ApplicationEndpoint.⌋

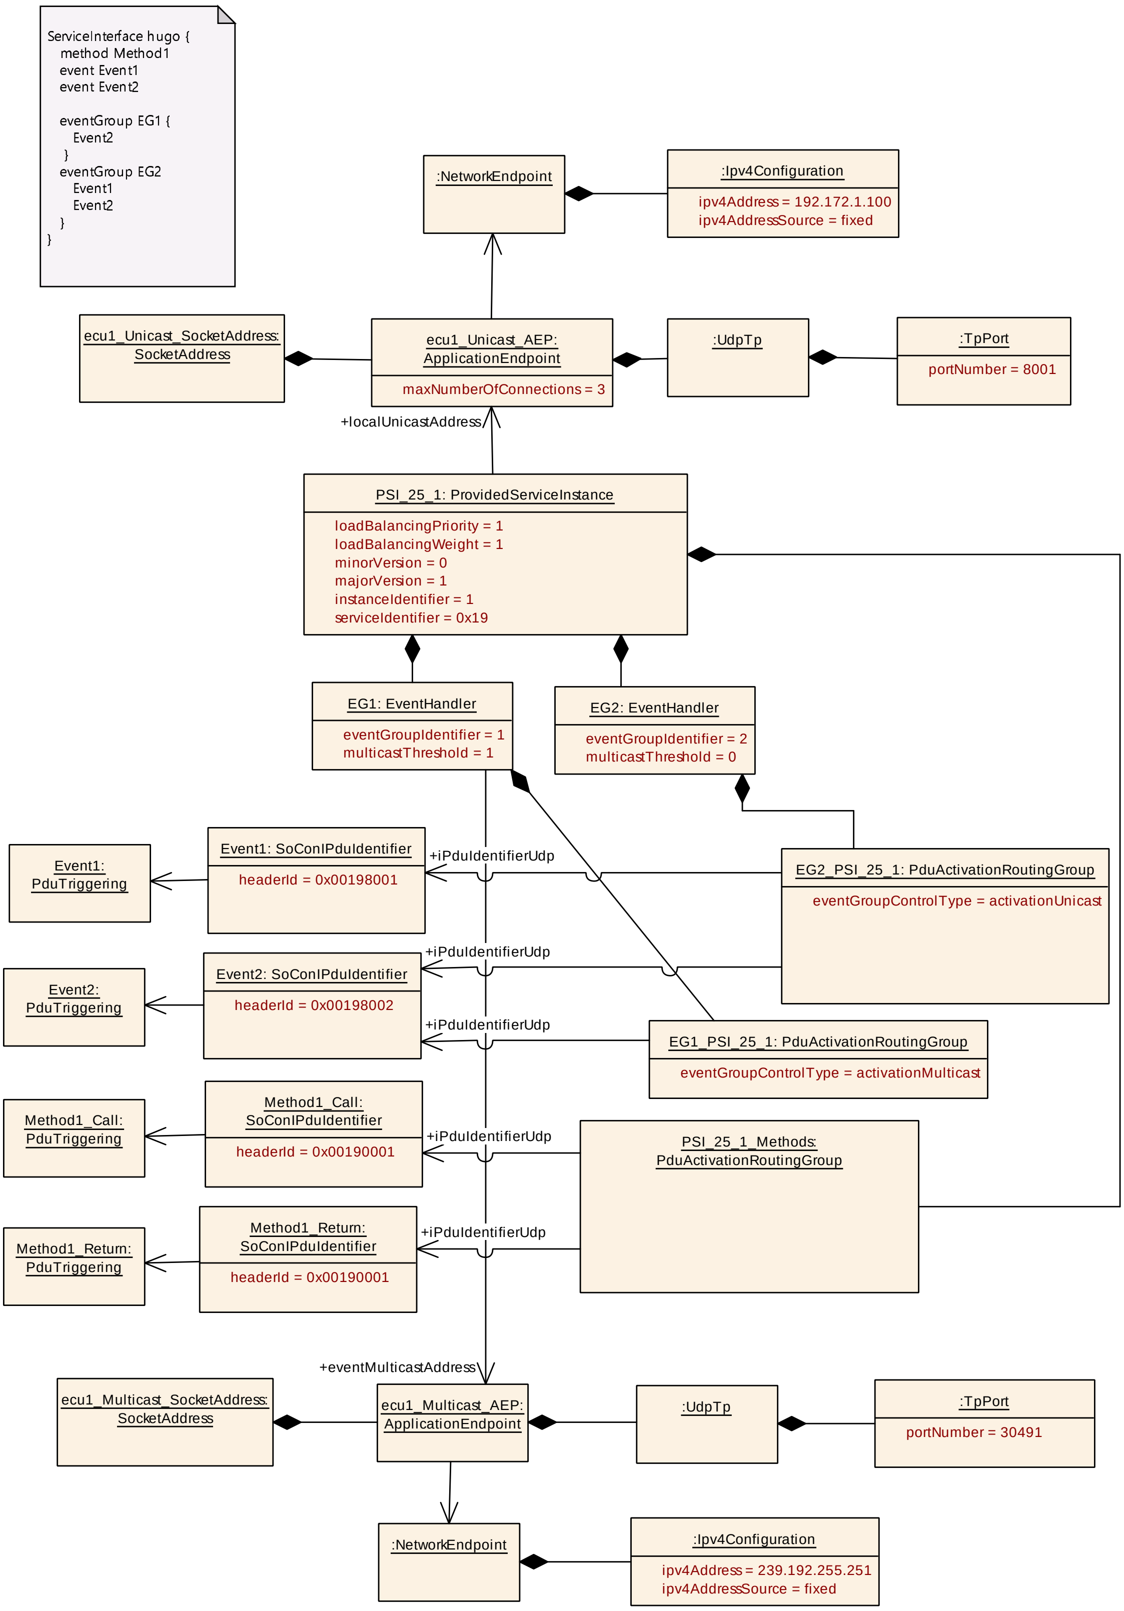

Figure 6.48: Example for the modeling of a `ProvidedServiceInstance` that is deployed on a local Unicast Endpoint

The example in Figure 6.48 shows a ProvidedServiceInstance named PSI_25_1 that is provided on Udp Port 8001 and IPv4 address 192.172.1.100. The Service that is represented by the ProvidedServiceInstance contains one method (named Method1) and two events (named Event1 and Event2). In addition the service contains two different event groups that are represented by two EventHandlers EG1 and EG2.

On VFB level the method is represented by a ClientServerOperation and each event by a VariableDataPrototype in a SenderReceiverInterface.

The ClientServerOperation is mapped by a ClientServerToSignalMapping to a callSignal and to a returnSignal that in turn are mapped via ISignals into an ISignalIPdu. Each VariableDataPrototype is mapped by the SenderReceiverToSignalMapping or by the SenderReceiverToSignalGroupMapping to one or several SystemSignals that in turn are mapped via ISignals into an ISignalIPdu.

The PduTriggerings of these ISignalIPdus are referenced by the SoConIPduIdentifier that assigns a headerId to each ISignalIPdu.

The event group EG2 contains Event1 and Event2 and the PduActivationRoutingGroup named EG2_PSI_25_1 activates the SoConIPduIdentifiers that are representing these two events for transmission over IP Unicast since the eventGroupControlType is set to activationUnicast.

The event group EG1 contains Event1 and the PduActivationRoutingGroup named EG1_PSI_25_1 activates the SoConIPduIdentifier for transmission over IP Multicast since the eventGroupControlType is set to activationMulticast. EventHandler EG1 has the multicastThreshold attribute set to 1. This means that the first client that will subscribe to this event group will be served via IP Multicast. This is the reason why the EventHandler EG1 points with the eventMulticastAddress to an IP Multicast address to which the event will be transmitted.

In the SoAd configuration such a System Description will result in a SoAdSocketConnectionGroup with a SoAdSocketLocalPort and SoAdSocketLocalAddressRef that are derived from the ApplicationEndpoint referenced in the localUnicastAddress role by the ProvidedServiceInstance.

The SoAdSocketConnectionGroup will contain three SoAdSocketConnections since the maxNumberOfConnections is set to 3 in this example. The ProvidedServiceInstance does not contain a remoteUnicastAddress reference. This means that Service Discovery is used and that the SoAdSocketRemoteIpAddress needs to be configured to ANY and the SoAdSocketRemotePort to 0 in all three SoAdSocketConnections.

In addition one multicast SoAdSocketConnection will be added to the SoAdSocketConnectionGroup since the EventHandler EG1 points with the eventMulticastAddress to a multicast address.

6.7.5.5.2 SOME/IP ConsumedServiceInstance

The ConsumedServiceInstance is used to define a SOME/IP Service consumer. Please note that in the AUTOSAR model all necessary information about the searched service is configurable on the client side. A model that contains only the ConsumedServiceInstance description is sufficient for the configuration of the EcuInstance to which the ConsumedServiceInstance is deployed. This is different to former versions of the System Template. The design criterion for the model was to disentangle the ProvidedServiceInstance and the ConsumedServiceInstance from each other.

[TPS_SYST_02234] SOME/IP Service search

Upstream requirements: RS_SYST_00039

⌈A defined ConsumedServiceInstance is searching for a SOME/IP Service Instance that fulfills all of the following conditions:

- Service Identifier that matches the value set in serviceIdentifier,
- Service Instance Identifier that matches the value set in instanceIdentifier
- Service major version that matches the value set in majorVersion,
- Service minor version:
  - in case versionDrivenFindBehavior = exactOrAnyMinorVersion: Service minor version that matches the value set in minorVersion or *ANY* minor version of the Service Instance in case the minorVersion is set to *ANY*
  - in case versionDrivenFindBehavior = minimumMinorVersion: Service minor version that matches at least the value set in minorVersion or is higher

⌋

[constr_5110] Search for a collection of ServiceInstances is not supported

Imposition time: IT_SysDesc

⌈The ConsumedServiceInstance.instanceIdentifier is not allowed to be set to the value ANY or ALL.⌋

The reason for [constr_5110] is that the AUTOSAR SD module is only able to send wildcard finds for a Minor Version. The search for a collection of ServiceInstances is not supported by the Classic Platform Basic Software.

Table 6.168: ConsumedServiceInstance

[TPS_SYST_03050] Usage of ConsumedServiceInstance.blocklistedVersion

Status: DRAFT

⌈A service connection of a ConsumedServiceInstance to a ProvidedServiceInstance is not considered for service discovery if the SomeipServiceVersion.minorVersion exists in the collection of SomeipServiceVersions aggregated at the ConsumedServiceInstance in the role blocklistedVersion.⌋

A typical scenario for using a blocklist may be: For a certain ConsumedServiceInstance a certain compatible provider service version inside a system may not work which may have been identified after the design phase. In order to keep the system running this certain provider version won't be considered in the service search if it has been blocklisted. Therefore, the ConsumedServiceInstance may connect only to ProvidedServiceInstances that fulfill the search criteria and are not blocklisted.

[constr_3559] ConsumedServiceInstance.blocklistedVersion is restricted to the usage of minorVersion

Status: DRAFT
Imposition time: IT_SysDesc

⌈The majorVersion attribute shall not be used in the SomeipServiceVersion that is aggregated by the ConsumedServiceInstance in the role blocklistedVersion.⌋

[TPS_SYST_02235] ConsumedServiceInstance deployment

Upstream requirements: RS_SYST_00039

⌈The deployment of a ConsumedServiceInstance to an EcuInstance is realized in two ways:

- if the localUnicastAddress reference is available then the referenced ApplicationEndpoint defines the TCP/UDP Port and the NetworkEndpoint that is referenced by the ApplicationEndpoint defines the IP Address on which the service consumer is located. Over the defined TCP/UDP port the service consumer sends out the method calls to a service provider that was found by the Service Discovery search. The endpoint information is also transported in the SOME/IP SubscribeEventGroup message to the server to indicate on which address the incoming events are expected. With the SocketAddress.connector reference the deployment to an EcuInstance is achieved.

- if the localUnicastAddress reference is not available (in case Events are received via IP Multicast only as described by [TPS_SYST_02302] and the aggregating ConsumedServiceInstance does not define any methods) then the ApplicationEndpoint that is referenced by the eventMulticastAddress reference from the ConsumedEventGroup shall be EcuInstance specific and the SocketAddress that contains the referenced ApplicationEndpoint is allowed to reference only a single EthernetCommunicationConnector in the multicastConnector role. With this SocketAddress.multicastConnector reference the deployment to an EcuInstance is achieved.

⌋

Please note that the Service provider and the Service consumer do not need to find each other if the ConsumedServiceInstance contains a remoteUnicastAddress reference to an ApplicationEndpoint. If this reference is set, the client will not get the server's address from the Service Offer message.

The client already knows the address of the service provider from the configuration and all necessary socket connections can be set up from this configuration information. The client still needs to subscribe to event groups that are of interest for it in this setup.

[TPS_SYST_02236] Static configuration between ConsumedServiceInstance and ProvidedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ConsumedServiceInstance contains a remoteUnicastAddress reference to an ApplicationEndpoint the SoAd will setup one single SocketConnection between the localUnicastAddress and the remoteUnicastAddress.⌋

[TPS_SYST_02237] Maximal number of servers that may connect to the local client address

Upstream requirements: RS_SYST_00039

⌈If the ConsumedServiceInstance references an ApplicationEndpoint in the role localUnicastAddress and the remoteUnicastAddress is not defined then the attribute ApplicationEndpoint.maxNumberOfConnections defines the maximal number of remote endpoints that will be able to connect to this local client address. The SoAd will setup a SocketConnection for each potential remote endpoint. The local Address of the SocketConnection is derived from ConsumedServiceInstance.localUnicastAddress. The remote Address is set to ANY address in case that the remoteUnicastAddress is not used.⌋

[constr_5085] ConsumedServiceInstance.localUnicastAddress shall be IP Unicast

Imposition time: IT_SysDesc

⌈If defined, the ConsumedServiceInstance.localUnicastAddress shall point to an IP Unicast address.⌋

In other words the localUnicastAddress is not allowed to point to a IP Multicast address. Please note that the ConsumedServiceInstance.localUnicastAddress does not need to be set in all cases as specified in [TPS_SYST_02238].

[constr_5086] ConsumedServiceInstance.remoteUnicastAddress shall be IP Unicast

Imposition time: IT_SysDesc

⌈The ConsumedServiceInstance.remoteUnicastAddress shall point to an IP Unicast address.⌋

Please note that a Service may provide some portions (Events, Methods) over TCP and and other portions over UDP. This is the reason why the ConsumedServiceInstance is able to reference up to two localUnicastAddresses.

[TPS_SYST_02238] ConsumedServiceInstance.localUnicastAddress reference target

Upstream requirements: RS_SYST_00039

⌈The ConsumedServiceInstance is allowed to have:

- a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP Port,
- a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP Port,
- a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP Port and a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP Port.
- no configured localUnicastAddress.

⌋

The Routing Group Activation is controlled in AUTOSAR by the Service Discovery module.

[TPS_SYST_02239] Methods consumed by a ConsumedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ConsumedServiceInstance finds the searched service then the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup is activated. All Methods that are provided by the found ProvidedServiceInstance can by called by ConsumedServiceInstance.⌋

Please note that according to [TPS_SYST_02151] the relationship between the call and return is achieved by means of meta data items attached to the Pdus by the Socket Adapter.

[TPS_SYST_02240] Service methods consumed over UDP

Upstream requirements: RS_SYST_00039

⌈Method Pdus (Call and Return ISignalIPdus) of a ConsumedServiceInstance that are accessed over UDP are described by SoConIPduIdentifiers referenced by the iPduIdentifierUdp reference from the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup by the ConsumedServiceInstance.⌋

[TPS_SYST_02241] Service methods consumed over TCP

Upstream requirements: RS_SYST_00039

⌈Method Pdus (Call and Return ISignalIPdus) of a ConsumedServiceInstance that are accessed over TCP are described by SoConIPduIdentifiers referenced by the iPduIdentifierTcp reference from the PduActivationRoutingGroup that is aggregated in the role methodActivationRoutingGroup by the ConsumedServiceInstance.⌋

[TPS_SYST_02242] Subscription to a SOME/IP Event group

Upstream requirements: RS_SYST_00039

⌈A ConsumedServiceInstance subscribes to a published event group via a ConsumedEventGroup that is aggregated in the role consumedEventGroup. The eventGroupIdentifier identifies the SOME/IP Event Group in the context of the ConsumedServiceInstance to which the consumer subscribes.⌋

Class	**ConsumedEventGroup**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances

Table 6.169: ConsumedEventGroup

[TPS_SYST_02243] Reception of events over UDP/TCP Port in case of Service Discovery

Upstream requirements: RS_SYST_00039

⌈The events of an event group that are described by an ConsumedEventGroup are received either:

- via IP Unicast on the UDP/TCP Port that is defined by the ApplicationEndpoint that is referenced by the ConsumedServiceInstance in the role localUnicastAddress or
- via IP Multicast:
  - in case of dynamic SD configuration the Multicast IP Address and UDP Port to which the events are transmitted will be provided by the server at runtime in the SOME/IP SubscribeEventGroupAck message,
  - in case of static configuration the Multicast IP Address and UDP Port to which the events are transmitted shall be configured by ConsumedEventGroup.eventMulticastAddress.

⌋

Please note that the ConsumedEventGroup.eventMulticastAddress shall also be used in case of a dynamic SD Configuration where the client learns the multicast address at runtime. In this case the ApplicationEndpoint and the corresponding NetworkEndpoint that are referenced by eventMulticastAddress define a resource in the TcpIp module where the multicast address that will be determined at runtime will be stored. Since the referenced ApplicationEndpoint and the corresponding NetworkEndpoint are placeholders the configured TP Port and IP address shall be set to ANY.

There are different scenarios that are considered:

- The same multicast address is used by all potential servers. On the client a resource for this single multicast address needs to be reserved. All ConsumedEventGroups need to reference the same placeholder ApplicationEndpoint with eventMulticastAddress. In the Ecu Configuration one TcpIpLocalAddr container is created from the placeholder ApplicationEndpoint. In addition one SoAdSocketConnectionGroup is created that points with the SoAdSocketLocalAddressRef to the TcpIpLocalAddr container. All Pdus received over multicast are assigned to this SoAdSocketConnectionGroup.

- The server is using different multicast addresses, e.g. Multicast Address A for EventHandler A and Multicast Address B for EventHandler B. On the client side resources for all used multicast addresses need to be reserved. In the example the ConsumedEventGroup A needs to reference one placeholder ApplicationEndpoint with eventMulticastAddress. The ConsumedEventGroup B needs to reference a second placeholder ApplicationEndpoint with eventMulticastAddress. In the Ecu Configuration a TcpIpLocalAddr container is created for each used placeholder. In addition one SoAdSocketConnectionGroup per placeholder is created. In the example the Pdus of ConsumedEventGroup A are assigned to one SoAdSocketConnectionGroup and Pdus of ConsumedEventGroup B are assigned to the second SoAdSocketConnectionGroup. With this approach it is possible to define at configuration time which Pdus share the same multicast address, and which ones are going over different multicast addresses.

If more than one multicast address is used it is not known at configuration time which server will publish which address at which point in time. The configuration needs to be prepared for all possible scenarios. Please be aware that this comes with a high resource consumption.

[constr_3262] ConsumedEventGroup.eventGroupIdentifier is mandatory

Imposition time: IT_SysDesc

⌈The ConsumedEventGroup.eventGroupIdentifier is mandatory.⌋

[constr_3457] Uniqueness of ConsumedEventGroup.eventGroupIdentifier in the scope of a ConsumedServiceInstance

Imposition time: IT_SysDesc

⌈Each ConsumedEventGroup that is aggregated by a ConsumedServiceInstance shall have a unique eventGroupIdentifier value in the scope of the aggregating ConsumedServiceInstance.⌋

[TPS_SYST_02245] Event groups consumed by a ConsumedServiceInstance

Upstream requirements: RS_SYST_00039

⌈If the ConsumedServiceInstance subscribes to an event group then the PduActivationRoutingGroup that is aggregated in the role pduActivationRoutingGroup by an ConsumedEventGroup is activated.⌋

[TPS_SYST_02246] PduActivationRoutingGroups for ConsumedEventGroups
⌈The PduActivationRoutingGroup that is aggregated by the ConsumedEventGroup in the role pduActivationRoutingGroup enables the routing of a group of Pdus that are related to the PduActivationRoutingGroup via the referenced SoConIPduIdentifiers.

- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationUnicast enables the receiving of events over IP Unicast.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationMulticast enables the receiving of events over IP Multicast.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to triggerUnicast enables the receiving of initial events that are sent out by the server immediately after the client got subscribed. This PduActivationRoutingGroup can used for SOME/IP Field notifiers.
- The PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationAndTriggerUnicast enables the routing over IP Unicast and makes sure that initial events are sent out by the server immediately after the client got subscribed. This PduActivationRoutingGroup can be used for SOME/IP Field notifiers.

⌋

[constr_5087] PduActivationRoutingGroup with eventGroupControlType set to activationUnicast or triggerUnicast or activationAndTriggerUnicast that is referenced by a ConsumedEventGroup

Imposition time: IT_SysDesc

⌈A ConsumedEventGroup that aggregates a PduActivationRoutingGroup with the PduActivationRoutingGroup.eventGroupControlType set to activationUnicast or triggerUnicast or activationAndTriggerUnicast shall be aggregated by a ConsumedServiceInstance that has a localUnicastAddress reference that points to an IP Unicast Address.⌋

[TPS_SYST_02247] Events consumed over UDP

Upstream requirements: RS_SYST_00039

⌈Pdus of an ConsumedEventGroup that are consumed over UDP are described by SoConIPduIdentifiers referenced by the iPduIdentifierUdp reference from the PduActivationRoutingGroup that is aggregated in the role pduActivationRoutingGroup by the ConsumedEventGroup.⌋

[TPS_SYST_02248] Events consumed over TCP

Upstream requirements: RS_SYST_00039

[constr_5088] PduActivationRoutingGroup with iPduIdentifierTcp reference that is aggregated by a ConsumedServiceInstance

Imposition time: IT_SysDesc

⌈If the PduActivationRoutingGroup contains the iPduIdentifierTcp reference then the aggregating ConsumedServiceInstance shall contain a localUnicastAddress reference to an ApplicationEndpoint that defines a TCP address.⌋

[constr_5089] PduActivationRoutingGroup with iPduIdentifierUdp reference that is aggregated by a ConsumedServiceInstance

Imposition time: IT_SysDesc

⌈If the PduActivationRoutingGroup contains the iPduIdentifierUdp reference then the aggregating ConsumedServiceInstance shall contain a localUnicastAddress reference to an ApplicationEndpoint that defines a UDP address.⌋

[TPS_SYST_02014] ConsumedEventGroup priority ⌈The priority in the ConsumedEventGroup shall be used as Ethernet Header information together with the vlanIdentifier. If defined the priority overwrites the defaultPriority that is defined in the VlanMembership, the priority that is defined at the NetworkEndpoint and the priority that is defined at the ApplicationEndpoint.⌋

[constr_5090] ApplicationEndpoints referenced by ConsumedEventGroups and by the aggregating ConsumedServiceInstance shall be in the same VLAN

Imposition time: IT_SysDesc

⌈The ApplicationEndpoint that is referenced by an ConsumedEventGroup in the role eventMulticastAddress shall belong to the same VLAN (EthernetPhysicalChannel) as the ApplicationEndpoint that is referenced by the localUnicastAddress reference from the ConsumedServiceInstance that aggregates the ConsumedEventGroup.⌋

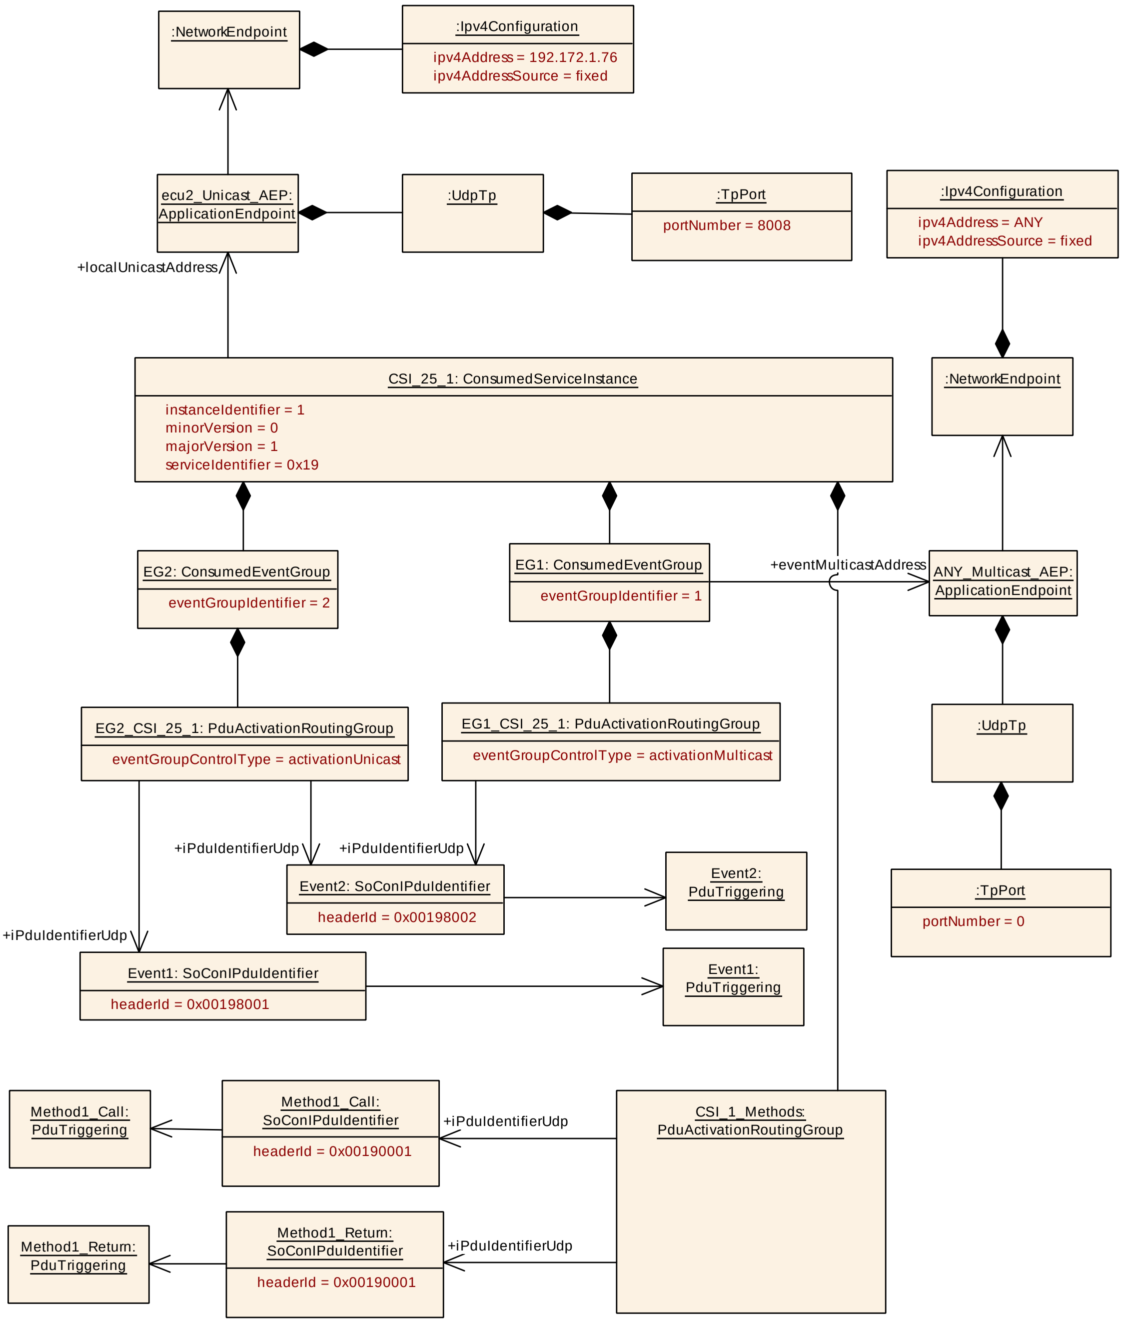

Figure 6.49: Example for the modeling of a ConsumedServiceInstance that is deployed on a local Unicast Endpoint

The example in Figure 6.49 shows a ConsumedServiceInstance named CSI_25_1 that is deployed on Udp Port 8008 and IPv4 address 192.172.1.76. The Service that is represented by the ConsumedServiceInstance contains one method (named Method1) and two events (named Event1 and Event2). In addition the service contains two different event groups that are represented by two ConsumedEventGroups EG1 and EG2.

The PduTriggerings for the ISignalIPdus that transport the events, the method call and the method response are referenced by the SoConIPduIdentifier that assigns a headerId to each ISignalIPdu.

The event group EG2 contains Event1 and Event2 and the PduActivationRoutingGroup named EG2_CSI_25_1 activates the SoConIPduIdentifiers that are representing these two events for transmission over IP Unicast since the eventGroupControlType is set to activationUnicast.

The event group EG1 contains Event1 and the PduActivationRoutingGroup named EG1_CSI_25_1 activates the SoConIPduIdentifier for transmission over IP Multicast since the eventGroupControlType is set to activationMulticast.

In the SoAd configuration such a System Description will result in a SoAdSocketConnectionGroup with a SoAdSocketLocalPort and SoAdSocketLocalAddressRef that are derived from the ApplicationEndpoint referenced in the localUnicastAddress role by the ConsumedServiceInstance.

The SoAdSocketConnectionGroup will contain one single SoAdSocketConnection since the maxNumberOfConnections is not set in this example. The ProvidedServiceInstance does not contain a remoteUnicastAddress reference. This means that Service Discovery is used and that the SoAdSocketRemoteIpAddress needs to be configured to ANY and the SoAdSocketRemotePort to 0 in the SoAdSocketConnection.

Since only a single multicast placeholder ApplicationEndpoint is referenced with the eventMulticastAddress by all existing ConsumedEventGroups one multicast SoAdSocketConnectionGroup needs to be created with two SoAdSocketConnections.

6.7.5.5.2.1 ConsumedServiceInstance with multicast only reception

A ProvidedServiceInstance may be configured to directly use multicast for the transport of the Events of an EventGroup (EventHandler.multicastThreshold = 1). In this case it is not required for a Client to have a unicast socket prepared if the server will always use the multicast transport.

In order to take benefit of a “multicast only event transport” on Client side, the Client needs the system knowledge that a specific EventGroup will be transported by the Server using multicast only. Such an approach weakens the service discovery paradigm / disentangle approach, where Client and Server do not need to know the transport details. However, if there is the knowledge available, the Clients can be configured for “multicast only event transport”.

Note that a Server that is not configured to provide “only multicast event transport” for an EventGroup will reject a subscription with no unicast option configured, during runtime.

While the configuration of “multicast only event transport” on the ProvidedServiceInstance / EventHandler is obvious, the setup on the ConsumedServiceInstance has several implications.

The indication that a ConsumedEventGroup shall be received using multicast only transport is given by having only ConsumedEventGroup.pduActivationRoutingGroup aggregated where PduActivationRoutingGroup.eventGroupControlType is only set to activationMulticast.

[TPS_SYST_02302] Definition of multicast only reception of an EventGroup

Upstream requirements: RS_SYST_00039

⌈If a ConsumedEventGroup has aggregated one or several PduActivationRoutingGroups in the role pduActivationRoutingGroup and all of these PduActivationRoutingGroups have PduActivationRoutingGroup.eventGroupControlType set to activationMulticast then this ConsumedEventGroup is defined to only receive Events via multicast.⌋

[TPS_SYST_02244] ConsumedServiceInstance without a defined localUnicastAddress

Upstream requirements: RS_SYST_00039

⌈If a ConsumedServiceInstance does not have a defined localUnicastAddress then the events will be received over IP Multicast only.⌋

If the ConsumedServiceInstance receives events over IP Multicast only and does not define any methods (i.e. the ConsumedServiceInstance does not aggregate any PduActivationRoutingGroups in the role methodActivationRoutingGroup) that request the unicast configuration then the ConsumedServiceInstance.localUnicastAddress reference can be skipped as described by [TPS_SYST_02244]. In this case the SOME/IP message SubscribeEventGroup will not contain any endpoint options. But since the ConsumedServiceInstance is created for a specific EcuInstance and the localUnicastAddress is missing the connection of the ConsumedServiceInstance to a specific EcuInstance needs to be established in a different way. In this case the ApplicationEndpoint that is referenced by the eventMulticastAddress reference from the ConsumedEventGroup shall be EcuInstance specific. In other words the SocketAddress that contains the referenced ApplicationEndpoint shall reference only a single EthernetCommunicationConnector in the multicastConnector role.

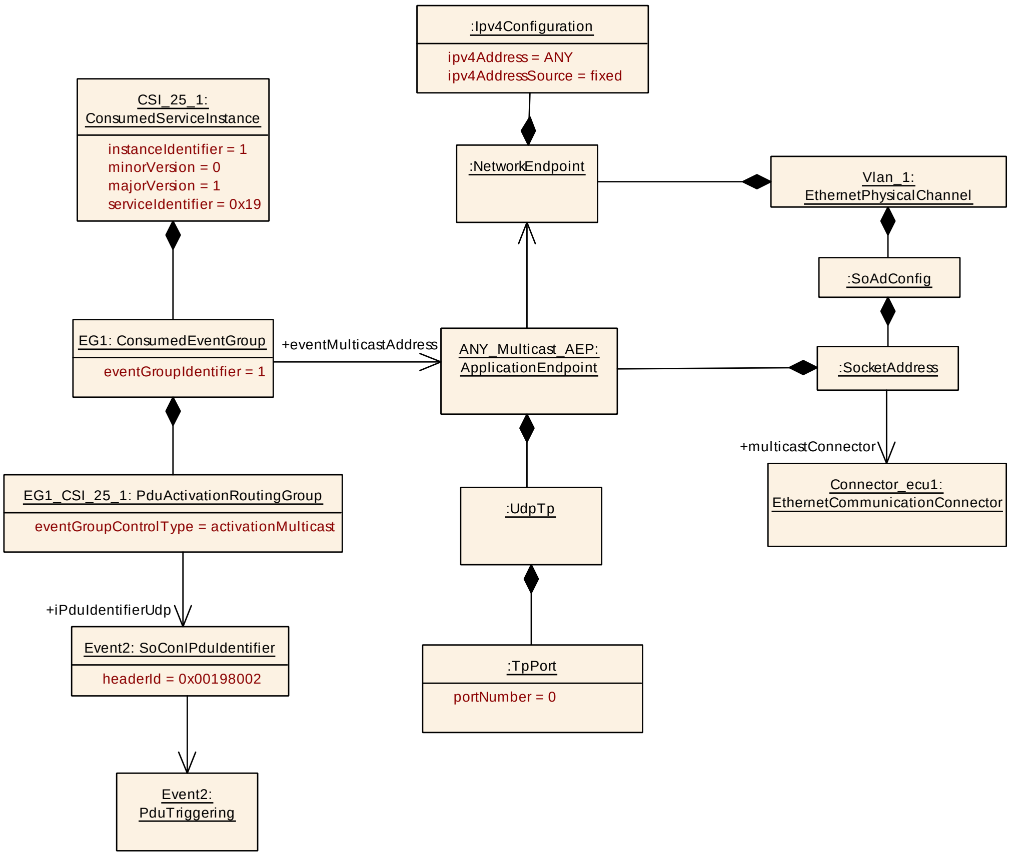

Figure 6.50: Example for the modeling of a ConsumedServiceInstance that is receiving Events over multicast only

6.7.5.5.3 SOME/IP Service Discovery Server Configuration

For every ProvidedServiceInstance on a Server different phases are existing where a suitable Service Discovery Message sending behavior is configurable:

- Down
- Available
  - Initial Wait Phase
  - Repetition Phase
  - Main Phase

[TPS_SYST_02249] Service Discovery Message sending behavior on ProvidedServiceInstance ⌈The Service Discovery Message sending behavior on a ProvidedServiceInstance is configurable with the SomeipSdServerServiceInstanceConfig that is referenced in the role sdServerTimerConfig.⌋

Attribute	**Type**	**Mult.**	**Kind**	**Note**
maxValue	TimeValue	0..1	attr	Maximum allowable response delay to entries received by multicast in seconds.
minValue	TimeValue	0..1	attr	Minimum allowable response delay to entries received by multicast in seconds.

Table 6.172: RequestResponseDelay

[TPS_SYST_02174] Initial Wait Phase configuration for a ProvidedServiceInstance ⌈The Initial Wait Phase for a ProvidedServiceInstance is configured with the initialOfferBehavior and the two attributes initialDelayMinValue and initialDelayMaxValue.⌋

When a calculated random timer based on these min and max values expires, the first OfferService message will be sent out.

[constr_9215] Existence of InitialSdDelayConfig.initialDelayMaxValue aggregated by SomeipSdServerServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each InitialSdDelayConfig that is aggregated by a SomeipSdServerServiceInstanceConfig in the role initialOfferBehavior, the attribute initialDelayMaxValue shall exist.⌋

[constr_9216] Existence of InitialSdDelayConfig.initialDelayMinValue aggregated by SomeipSdServerServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each InitialSdDelayConfig that is aggregated by a SomeipSdServerServiceInstanceConfig in the role initialOfferBehavior, the attribute initialDelayMinValue shall exist.⌋

[TPS_SYST_02258] Shared random timer for ProvidedServiceInstance service discovery ⌈If several ProvidedServiceInstances reference the same SomeipSdServerServiceInstanceConfig in the role of sdServerTimerConfig and if it is ensured that all ProvidedServiceInstances are requested / released in the same point in time (e.g. assigned to the same ConsumedProvidedServiceInstanceGroup and referenced only by one ConsumedProvidedServiceInstanceGroup, or all referencing ProvidedServiceInstances has set autoAvailable to TRUE and no runtime changes to the availability is performed), then the timing behavior is shared between the referencing ProvidedServiceInstances. Thus, if the calculated random timer based on the min and max values of the InitialSdDelayConfig expires, then OfferService entries of all referencing ProvidedServiceInstances shall be sent out.⌋

[TPS_SYST_02259] Shared random timer for ProvidedServiceInstance service discovery ⌈If several ProvidedServiceInstances reference the same SomeipSdServerServiceInstanceConfig in the role of sdServerTimerConfig and if it cannot be ensured that all ProvidedServiceInstances are requested / released in the same point in time, then the timing behavior is handled per ProvidedServiceInstance. The timing behavior shall be derived from the referenced SomeipSdServerServiceInstanceConfig for each referencing ProvidedServiceInstance.⌋

Note: [TPS_SYST_02259] supports an efficient modeling if timing behaviors are equal for the referencing ProvidedServiceInstances.

[TPS_SYST_02260] Individual random timer for ProvidedServiceInstance service discovery ⌈If ProvidedServiceInstances reference their own SomeipSdServerServiceInstanceConfig in the role of sdServerTimerConfig, then the timing behavior is handled per ProvidedServiceInstance. Thus, every ProvidedServiceInstance has its own calculated random timer based on the min and max value of the InitialSdDelayConfig. If the calculated random timer expires, then a OfferService entry of the referencing ProvidedServiceInstance shall be sent out.⌋

Note: [TPS_SYST_02260] enables a scattering of OfferService within the configured min and max value of the InitialSdDelayConfig of different ProvidedServiceInstances.

[TPS_SYST_02175] Repetition Wait Phase configuration for a ProvidedServiceInstance ⌈The Repetition Wait Phase for a ProvidedServiceInstance is configured with the initialOfferBehavior and the two attributes initialRepetitionsMax and initialRepetitionsBaseDelay.⌋

If the Repetition Phase is entered the Service Discovery waits for the initialRepetitionsBaseDelay and transmits an OfferService entry. If the amount of sent OfferService entries reaches initialRepetitionsMax the Main Phase will be entered.

If initialRepetitionsMax is configured to 0 the Repetition Phase will be skipped and the Main Phase will be entered.

[TPS_SYST_02176] Main Phase configuration for a ProvidedServiceInstance ⌈The Main Phase for a ProvidedServiceInstance is configured with the offerCyclicDelay attribute of SomeipSdServerServiceInstanceConfig.⌋

The OfferService entry will be sent cyclically with an interval that is defined by the value of attribute offerCyclicDelay.

[TPS_SYST_02177] TTL for Offer Service Entries ⌈The lifetime of a ProvidedServiceInstance is configurable with the serviceOfferTimeToLive attribute of SomeipSdServerServiceInstanceConfig.

If the time that is configured by serviceOfferTimeToLive expires the ProvidedServiceInstance will no longer be offered.

If the offerCyclicDelay attribute of SomeipSdServerServiceInstanceConfig is not configured, or the configured value of offerCyclicDelay is 0, then the configured value of serviceOfferTimeToLive shall be ignored and the infinite value (0xFFFF) shall be used instead.⌋

[constr_9217] Existence of SomeipSdServerServiceInstanceConfig.serviceOfferTimeToLive

Imposition time: IT_SysDesc

⌈For each SomeipSdServerServiceInstanceConfig, the attribute serviceOfferTimeToLive shall exist.⌋

[TPS_SYST_02178] Servers RequestResponseDelay for received FindService entries ⌈The Server will delay the OfferService answer to a received multicast FindService entry by the configured SomeipSdServerServiceInstanceConfig.requestResponseDelay.

The actual delay will be randomly chosen between the maxValue and minValue.⌋

[constr_9218] Existence of RequestResponseDelay.minValue aggregated by SomeipSdServerServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each RequestResponseDelay that is aggregated by a SomeipSdServerServiceInstanceConfig in the role requestResponseDelay, the attribute minValue shall exist.⌋

[constr_9219] Existence of RequestResponseDelay.maxValue aggregated by SomeipSdServerServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each RequestResponseDelay that is aggregated by a SomeipSdServerServiceInstanceConfig in the role requestResponseDelay, the attribute maxValue shall exist.⌋

The ProvidedServiceInstance aggregates an EventHandler in the role eventHandler that allows to define service instance specific configuration settings for a SOME/IP EventGroup. The EventGroup specific timing settings are configured in the SomeipSdServerEventGroupTimingConfig that is referenced by the EventHandler in the role sdServerEgTimingConfig.

Class	**SomeipSdServerEventGroupTimingConfig**

[constr_9221] Existence of RequestResponseDelay.maxValue aggregated by SomeipSdServerEventGroupTimingConfig

Imposition time: IT_SysDesc

⌈For each RequestResponseDelay that is aggregated by a SomeipSdServerEventGroupTimingConfig in the role requestResponseDelay, the attribute maxValue shall exist.⌋

6.7.5.5.4 SOME/IP Service Discovery Client Configuration

For every ConsumedServiceInstance on a Client different phases are existing:

- Down
- Requested
  - Initial Wait Phase
  - Repetition Phase
  - Main Phase

[TPS_SYST_02250] Service Discovery Message sending behavior on ConsumedServiceInstance ⌈The Service Discovery Message sending behavior on a ConsumedServiceInstance is configurable with the SomeipSdClientServiceInstanceConfig that is referenced in the role sdClientTimerConfig.⌋

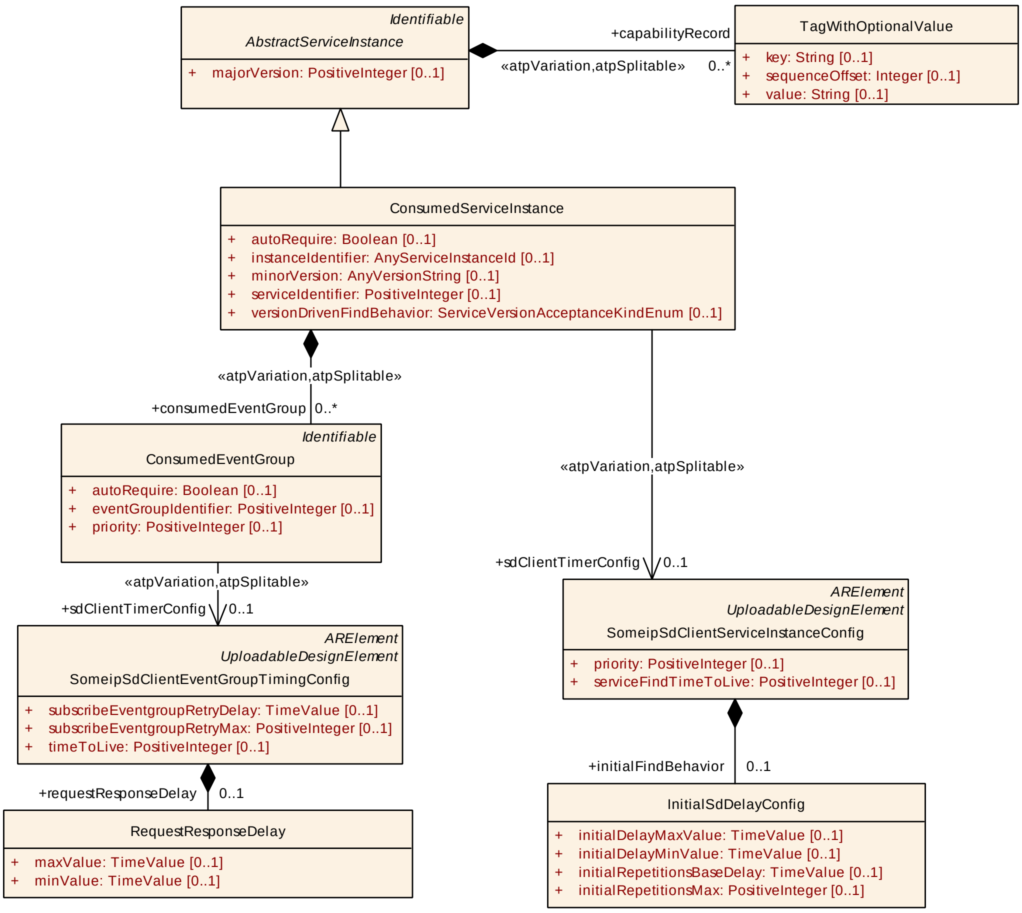

Figure 6.52: Model of SD Client Timing

[TPS_SYST_02183] Initial Wait Phase configuration for a ConsumedServiceInstance ⌈The Initial Wait Phase for a ConsumedServiceInstance is configured with the initialFindBehavior and the two attributes initialDelayMinValue and initialDelayMaxValue.⌋

If a calculated random timer based on these min and max values expires the first FindService entry will be sent out. When the calculated random timer expires and no OfferService is received the Repetition Phase will be entered.

[constr_9210] Existence of InitialSdDelayConfig.initialDelayMaxValue aggregated by SomeipSdClientServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each InitialSdDelayConfig that is aggregated by a SomeipSdClientServiceInstanceConfig in the role initialFindBehavior, the attribute initialDelayMaxValue shall exist.⌋

[constr_9211] Existence of InitialSdDelayConfig.initialDelayMinValue aggregated by SomeipSdClientServiceInstanceConfig

Imposition time: IT_SysDesc

⌈For each InitialSdDelayConfig that is aggregated by a SomeipSdClientServiceInstanceConfig in the role initialFindBehavior, the attribute initialDelayMinValue shall exist.⌋

[TPS_SYST_02261] Shared random timer for ConsumedServiceInstance service discovery ⌈If several ConsumedServiceInstances reference the same SomeipSdClientServiceInstanceConfig in the role of sdClientTimerConfig and if it is ensured that all ConsumedServiceInstances are requested / released in the same point in time (e.g. assigned to the same ConsumedProvidedServiceInstanceGroup and referenced only by one ConsumedProvidedServiceInstanceGroup, or all referencing ConsumedServiceInstance has set autoRequire to TRUE and no runtime changes to the require state is performed), then the timing behavior is shared between the referencing ConsumedServiceInstances. Thus, if the calculated random timer based on the min and max values of the InitialSdDelayConfig expires, then FindService entries of all referencing ConsumedServiceInstances shall be sent out.⌋

[TPS_SYST_02262] Shared random timer for ConsumedServiceInstance service discovery ⌈If several ConsumedServiceInstances reference the same SomeipSdClientServiceInstanceConfig in the role of sdClientTimerConfig and if it cannot be ensured that all ConsumedServiceInstances are requested / released in the same point in time, then the timing behavior is handled per ConsumedServiceInstance. The timing behavior shall be derived from the referenced SomeipSdClientServiceInstanceConfig for each referencing ConsumedServiceInstance.⌋

Note: [TPS_SYST_02262] support an efficient modeling if timing behaviors are equal for the referencing ConsumedServiceInstances.

[TPS_SYST_02263] Individual random timer for ConsumedServiceInstance service discovery ⌈If ConsumedServiceInstances reference their own SomeipSdClientServiceInstanceConfig in the role of sdClientTimerConfig, then the timing behavior is handled per ConsumedServiceInstance. Thus, every ConsumedServiceInstance has its own calculated random timer based on the min and max value of the InitialSdDelayConfig. Thus, if the calculated random timer expires, then a FindService entry of the referencing ConsumedServiceInstance shall be sent out.⌋

Note: [TPS_SYST_02263] enables a scattering of FindServices within the configured min and max value of the InitialSdDelayConfig, respectively of different ConsumedServiceInstances.

[TPS_SYST_02184] Repetition Wait Phase configuration for a ConsumedServiceInstance ⌈The Repetition Wait Phase for a ConsumedServiceInstance is configured with the initialFindBehavior and the two attributes initialRepetitionsMax and initialRepetitionsBaseDelay.⌋

If the Repetition Phase is entered, the Service Discovery waits the initialRepetitionsBaseDelay and sends a FindService entry.

If the amount of sent FindService entries reaches initialRepetitionsMax and no OfferService is received the Main Phase will be entered. In the Main Phase no further FindService entries are sent by the client.

[TPS_SYST_02185] TTL for Find Service Entries ⌈The lifetime of a ConsumedServiceInstance is configurable with the serviceFindTimeToLive attribute of SomeipSdClientServiceInstanceConfig. Note! The TTL value for FindService entries shall be ignored by the server service, and the configuration is only kept for backward compatibility.⌋

The ConsumedServiceInstance aggregates a ConsumedEventGroup in the role consumedEventGroup that allows to define service instance specific configuration settings for a SOME/IP EventGroup. The EventGroup specific timing settings are configured in the SomeipSdClientEventGroupTimingConfig that is referenced by the ConsumedEventGroup in the role sdClientTimerConfig.

Class	**SomeipSdClientEventGroupTimingConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	This meta-class is used to specify configuration related to service discovery in the context of an event group on SOME/IP. **Tags:** atp.recommendedPackage=SomeipSdTimingConfigs			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
request ResponseDelay	RequestResponseDelay	0..1	aggr	The Service Discovery shall delay answers to unicast messages triggered by multicast messages (e.g. Subscribe Eventgroup after Offer Service).
subscribe Eventgroup RetryDelay	TimeValue	0..1	attr	This attribute defines the interval in seconds to re-trigger a subscription to a Eventgroup, if a retry to subscribe to a Eventgroup is configured (subscribeEventgroupRetryMax > 0).
subscribe Eventgroup RetryMax	PositiveInteger	0..1	attr	This attribute define the maximum counts of retries to subscribe to an Eventgroup. If the value is set to 0 no retry shall be done. If the value is set to 255 the retry shall be done as along as the Eventgroup is requested and no SubscribeEventGroupAck was received.
timeToLive	PositiveInteger	0..1	attr	Defines the time in seconds the subscription of this event is expected by the client. this value is sent from the client to the server in the SD-subscribeEvent message.

Table 6.174: SomeipSdClientEventGroupTimingConfig

[TPS_SYST_02187] SomeipSdClientEventGroupTimingConfig.timeToLive for SubscribeEventGroup Entries ⌈The lifetime of an event subscription is configurable with the timeToLive attribute of SomeipSdClientEventGroupTimingConfig that is aggregated by an ConsumedEventGroup in the role sdClientTimerConfig.

If the time that is configured by timeToLive expires the event subscription is canceled.⌋

[constr_9212] Existence of SomeipSdClientEventGroupTimingConfig.timeToLive

Imposition time: IT_SysDesc

⌈For each SomeipSdClientEventGroupTimingConfig, the attribute timeToLive shall exist.⌋

It is possible to define a retry for subscription to a ConsumedEventGroup. The retry is optional and used by a ConsumedServiceInstance. It could be used to speed up the recovery if a SOME/IP-SD message is lost (e.g. SubscribeEventGroupAck) and the interval between cyclic offers (SomeipSdServerServiceInstanceConfig.offerCyclicDelay) of the corresponding ProvidedServiceInstance are to large to get a fast recovery, or to speed up the subscription to a ConsumedEventGroup if an ConsumedEventGroup is requested somewhere between two cyclic offers.

The retry is configurable within SomeipSdServerServiceInstanceConfig by setting the subscribeEventgroupRetryMax value greater than 0 to define how often a retry shall be triggered and subscribeEventgroupRetryDelay to define the timing interval the retries shall be triggered. If subscribeEventgroupRetryMax is set to 255, the retry to subscribe to a ConsumedEventGroup shall be done as long as the ConsumedEventGroup is requested and no acknowledgment (SubscribeEventGroupAck) from the ProvidedServiceInstance was received.

[constr_5095] Relationship between the timing behavior of the ConsumedEventGroup retry and the timing behavior of an Offer message

Imposition time: IT_SysDesc

⌈The timing behavior for a retry to a ConsumedEventGroup (subscribeEventgroupRetryMax, subscribeEventgroupRetryDelay) shall not overlap to the timing behavior (SomeipSdServerServiceInstanceConfig.offerCyclicDelay) of the corresponding ProvidedServiceInstance.⌋

[constr_5096] ConsumedEventGroup with value subscribeEventgroupRetryMax set to 255

Imposition time: IT_SysDesc

⌈Retry to a ConsumedEventGroup with value subscribeEventgroupRetryMax set to 255 is only allowed if the SomeipSdServerServiceInstanceConfig.offerCyclicDelay is set 0 and serviceOfferTimeToLive is set to 0xffffff of the corresponding ProvidedServiceInstance.⌋

[TPS_SYST_02188] Clients RequestResponseDelay for received ServiceOffer entries ⌈The Client will delay the SubscribeEventGroup answer to a received ServiceOffer message by the configured SomeipSdClientEventGroupTimingConfig.requestResponseDelay that is aggregated by the ConsumedEventGroup in the role sdClientTimerConfig.

The actual delay will be randomly chosen between the maxValue and minValue.⌋

[constr_9213] Existence of RequestResponseDelay.minValue aggregated by SomeipSdClientEventGroupTimingConfig

Imposition time: IT_SysDesc

⌈For each RequestResponseDelay that is aggregated by a SomeipSdClientEventGroupTimingConfig in the role requestResponseDelay, the attribute minValue shall exist.⌋

[constr_9214] Existence of RequestResponseDelay.maxValue aggregated by SomeipSdClientEventGroupTimingConfig

Imposition time: IT_SysDesc

⌈For each RequestResponseDelay that is aggregated by a SomeipSdClientEventGroupTimingConfig in the role requestResponseDelay, the attribute maxValue shall exist.⌋

6.7.5.5.5 Group of ConsumedServiceInstances and ProvidedServiceInstances

The AUTOSAR ServiceDiscovery provide a mechanism of starting/stopping ConsumedProvidedServiceInstanceGroups. Therefore, several ConsumedServiceInstances and ProvidedServiceInstances, respectively, could by enclosed to a ConsumedProvidedServiceInstanceGroup.

Class	ConsumedProvidedServiceInstanceGroup			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	The AUTOSAR ServiceDiscovery is able to start and to stop ClientServices and Server Services,respectively, at runtime. A SdServiceGroup contains several ClientServices and Server Services, respectively. **Tags:** atp.recommendedPackage=ConsumedProvidedServiceInstanceGroups			
Base	*ARObject*, *CollectableElement*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
consumed ServiceInstance	ConsumedService Instance	*	ref	This reference assigns a set of ProvidedServiceInstances to the ConsumedProvidedServiceInstanceGroup. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=consumedServiceInstance.consumed ServiceInstance, consumedServiceInstance.variation Point.shortLabel vh.latestBindingTime=postBuild
providedService Instance	ProvidedService Instance	*	ref	This reference assigns a set of ConsumedService Instances to the ConsumedProvidedServiceInstance Group. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=providedServiceInstance.providedService Instance, providedServiceInstance.variationPoint.short Label vh.latestBindingTime=postBuild

Table 6.175: ConsumedProvidedServiceInstanceGroup

The ConsumedProvidedServiceInstanceGroup is mapped to a SdService-Group within the ECUC configuration. The SdServiceGroups could be accessed via dedicated APIs within the AUTOSAR ServiceDiscovery (Sd) module to start and stop the requested SdServiceGroup. For example, the SdServiceGroups could be switched according the requested partial network similar to ComISignalIPduGroup and therefore the PncMapping refers the ConsumedProvidedServiceInstance-Group in the role pncConsumedProvidedServiceInstanceGroup.

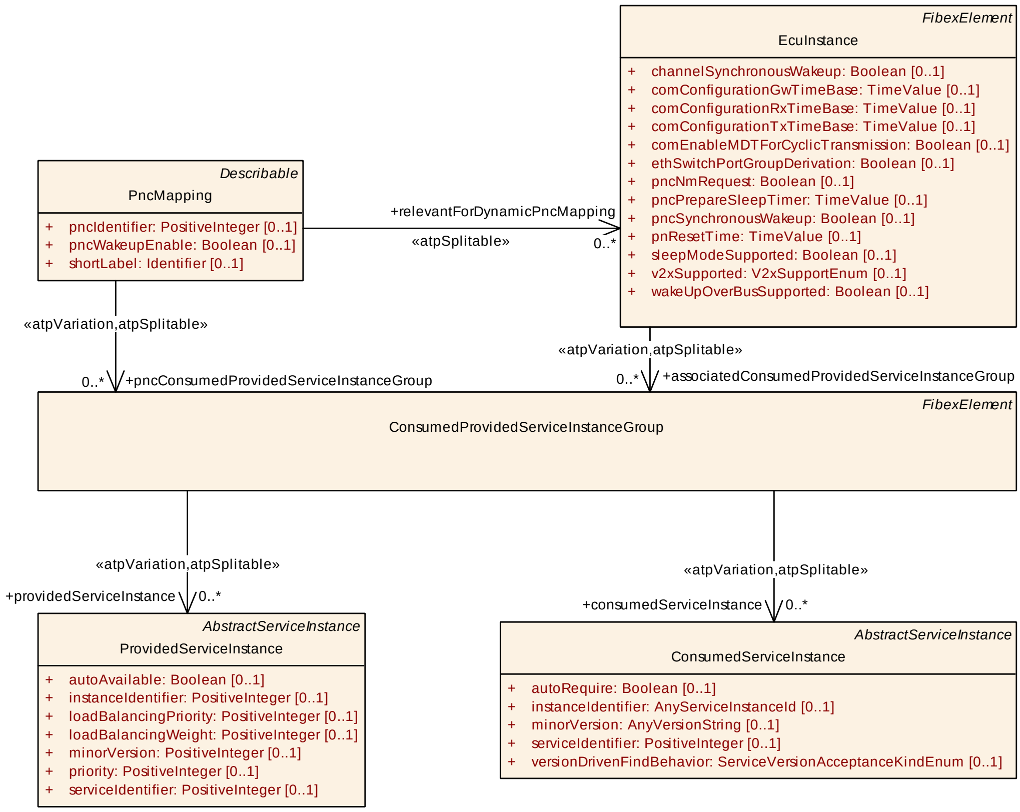

Figure 6.53: ConsumedProvidedServiceInstanceGroup

Starting a `ConsumedProvidedServiceInstanceGroup` would trigger the referencing `ConsumedServiceInstance`s to sent out *FindService* entries on the network and stopping a `ConsumedProvidedServiceInstanceGroup` would trigger the referencing `ConsumedServiceInstance`s to unsubscribe from the subscribed Event Groups and sent out an unsubscribe entry on the network.

Starting a `ConsumedProvidedServiceInstanceGroup` would trigger the referencing `ProvidedServiceInstance`s to sent out *OfferService* entries on the network and stopping a `ConsumedProvidedServiceInstanceGroup` would trigger the referencing `ProvidedServiceInstance`s to sent out a *StopOffer* entries on the network.

6.7.5.6 DDS Specific Description

In order to simplify the DDS configuration at EcuC level, the DDS-related model elements have been integrated into this document:

the DDS configuration at SystemTemplate level shall be used the derive the EcuC configuration of the DDS Entities, e.g. DDS DomainParticipants, Publishers, Subscribers, DataWriters, DataReaders.

DDS-specific model elements can be detailed both for **DDS signal-based communications** (a single `ISignal`, with `dataTypePolicy` set to `ddsSignal`, used to carry one DDS data, by means of DdsCpISignalToDdsTopicMapping) and for **DDS service-oriented communications** (by means of DdsCpServiceInstances, for details, refer to section 6.7.5.6.16).

Those model elements are grouped together by the DdsCpConfig, then they are linked to a ISignal or to a DdsCpServiceInstance by a reference to a DdsCp-Topic.

6.7.5.6.1 DDS Common Parameters

The DdsCpConfig class is a class used to group all the DDS relevant parameters.

At top level, a DDS Domain, characterized by its ID, is defined. A DDS Domain is used to isolate applications to each others: only entities belonging to the same DDS Domain can communicate with each other.

DDS Topics are part of a DDS Domain: each DDS Topic has visibility only inside a specific Domain, so Topics can be defined as part of a Domain.

A DDS Partition is used to logically group several Topics: it is possible to assign each Topic to one or more partitions (used to logically sub-partition a Domain). A Topic is characterized by a set of QoS policies.

The sections below give some details of the DdsCpConfig (and its sub-containers) architecture and the DdsCpQosProfile container.

6.7.5.6.16 DDS Service Instances

The DdsCpServiceInstance class is an abstract class that derives from the AbstractServiceInstance. It is used to define a DDS service instance and the DDS Topics associated to the service itself. This class combines attributes for both interface and instance parameters, and it is used for AP interoperability.

From this class, the DdsCpConsumedServiceInstance and DdsCpProvidedServiceInstance classes are derived.

A DdsCpServiceInstance can contain any combination of DdsCpServiceInstanceEvents and DdsCpServiceInstanceOperations, through the inherited classes DdsCpProvidedServiceInstance and DdsCpConsumedServiceInstance. For DDS, the exchange information unit is the Dds Topic. In this case, the definition of DdsCpProvidedServiceInstance and DdsCpConsumedServiceInstance is always required, even for fully static configuration: it is necessary to link ServiceInstance objects to DDS Topics, and not only to assign a ServiceId to be used during Service discovery.

Into a DdsCpServiceInstance there are different instances of DdsCpTopic to be mapped to AUTOSAR CP specific objects:

- One pair of DdsCpTopics (one for requests and one for replies) for all the Methods into the DdsCpServiceInstance: DdsCpServiceInstance.ddsMethodRequestTopic and DdsCpServiceInstance.ddsMethodReplyTopic

  All **method requests** for a single DdsCpServiceInstance are represented as a single topic that leverages DDS discriminated union types to pack method request identification (source, target, specific method ID within the service interface), along with the input parameter data.

  Similarly, all **method replies** for a single DdsCpServiceInstance are represented as a single topic (differently named from the one dedicated to requests) that leverages DDS discriminated union types to pack method reply identification (source, target, specific method ID within the service interface), along with the output parameter / error data.

- One pair of DdsCpTopics (one for requests and one for replies) for all the Fields into the DdsCpServiceInstance: DdsCpServiceInstance.ddsFieldRequestTopic and DdsCpServiceInstance.ddsFieldReplyTopic

  All **field get or set requests** for a single DdsCpServiceInstance are represented as a single topic that leverages DDS discriminated union types to pack field get/set identification (source, target, specific method ID within the service interface), along with the input parameter data.

  Similarly **all field get or set replies** for a single DdsCpServiceInstance are represented as a single topic (differently named from the one dedicated to requests) that leverages DDS discriminated union types to pack field get/set reply identification (source, target, specific method ID within the service interface), along with the output parameter / error data.

  Note: Field Notifiers behave exactly like DDS Events. They share the same topic naming conventions, type and DDS entity functionality.

- One DdsCpTopic for each DdsCpServiceInstanceEvent of the DdsCpServiceInstance. Each **event** and each **field notifier** is represented by its own topic.

[constr_3739] Value of ISignal.dataTypePolicy for all ISignals associated with a DdsCpServiceInstance

Imposition time: IT_EcuExt

⌈For all ISignals that are referenced by an ISignalToIPduMapping where the enclosing ISignalIPdu is only referenced by PduTriggerings that are in turn referenced in one of the roles:

- DdsCpServiceInstanceEvent.ddsEvent
- DdsCpServiceInstanceOperation.ddsOperationRequestTriggering
- DdsCpServiceInstanceOperation.ddsOperationResponseTriggering

The value of attribute ISignal.dataTypePolicy shall be set to ddsService.⌋

In the below picture the overall architecture of DdsCpServiceInstance class is depicted.

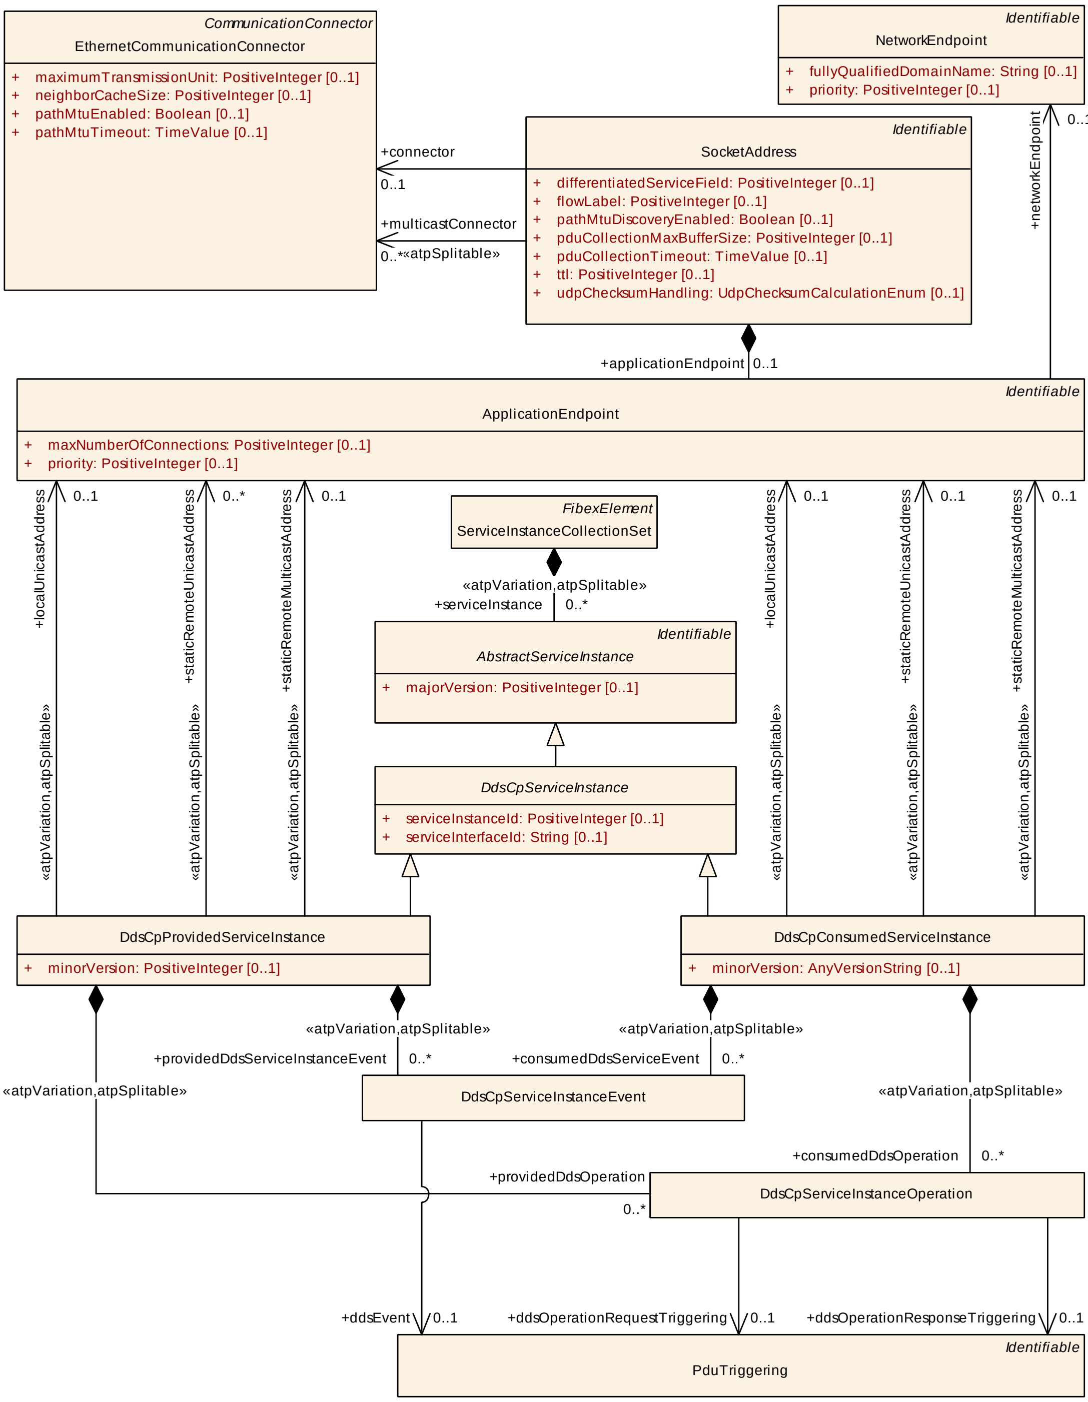

Figure 6.56: Dds Service Instance

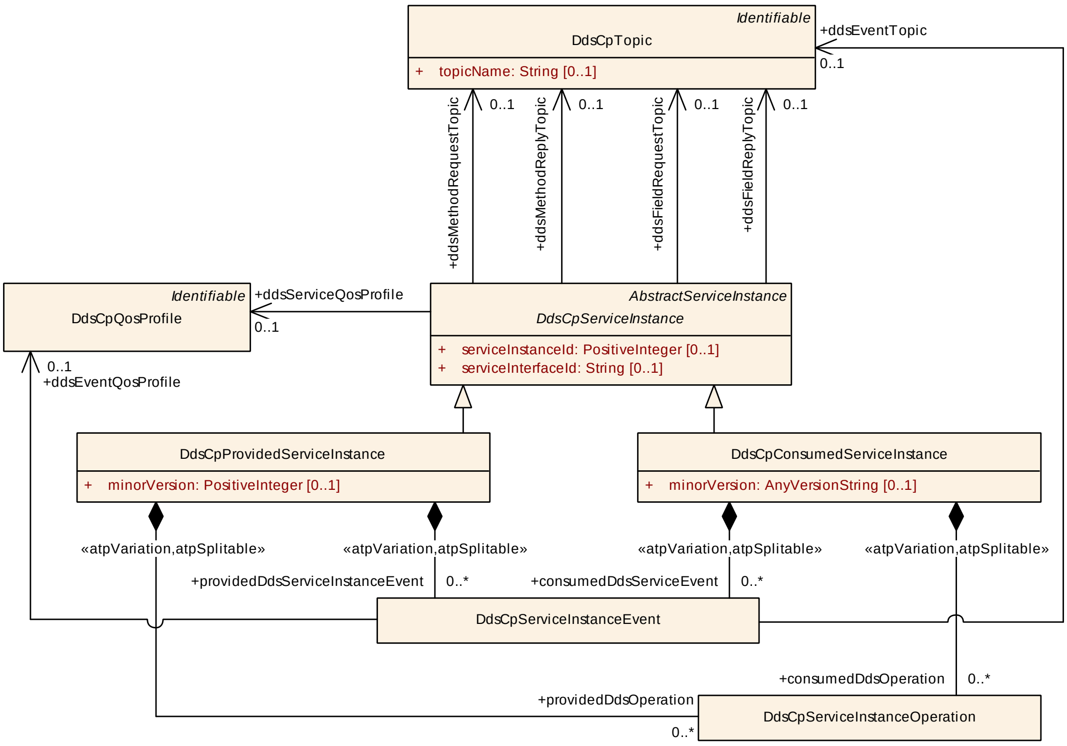

Figure 6.57: Dds Service Instance Topics

[TPS_SYST_03090] DDS Methods Request/Reply Topic ⌈The DdsMethodRequestTopic and DdsMethodReplyTopic references are used to specify the DdsCpTopic to be used respectively for Method requests and Methos replies.⌋

[TPS_SYST_03091] DDS Fields Request/Reply Topic ⌈The DdsFieldRequestTopic and DdsFieldReplyTopic references are used to specify the DdsCpTopic to be used respectively for Fields requests and Fields replies.⌋

The DdsCpServiceInstanceEvent class is used to define specific DDS parameters for events.

[constr_3740] Existence of DdsCpServiceInstanceEvent.ddsEventTopic

Imposition time: IT_EcuExt

⌈For each DdsCpServiceInstanceEvent, the reference in the role ddsEventTopic shall exist.⌋

[TPS_SYST_03093] DDS Operation ⌈The DdsCpServiceInstanceOperation class is used to define specific DDS parameters for Methods.⌋

[TPS_SYST_03094] DdsService QoS Profile ⌈The DdsCpQosProfile referenced in the role DdsCpServiceInstance.ddsServiceQosProfile shall be used to identify the QoS policy configuration that applies to the entire DdsCpServiceInstance.⌋

The DDS standard [27] defines QoS policies and their attributes, but not default values for the later: they are left to the final users. Besides, it is possible to have QoS profiles which are named sets of cohesive QoS policy attributes. In AUTOSAR, a DdsCpServiceInstance needs to define, at least, a QoS profile to apply to all the DDS entities that eventually represent the service events, methods and fields: DomainParticipant, Publisher, Subscriber, Topics, DataWriters and DataReaders. Because methods and field methods all operate under a limited set of 4 topics (as depicted in Figure 6.57), it is generally agreed to have these 4 inherit their QoS policy values from the Service Instance QoS profile

[constr_3735] Existence of DdsCpServiceInstance.ddsServiceQosProfile

Imposition time: IT_EcuExt

⌈For each DdsCpServiceInstance, the reference in the role ddsServiceQosProfile shall exist.

Note: This profile applies to the all 4 topics used for methods and fields defined into the DdsCpServiceInstance (e.g ddsMethodRequestTopic, ddsMethodReplyTopic), ddsFieldRequestTopic, ddsFieldReplyTopic).⌋

Because events have their own per-instance topic, resulting in their own DDS DataReader or DataWriter entities they are allowed to get their own QoS policy configuration, independent from the Service Instance one. If DdsCpServiceInstanceEvent does not define its own DdsCpQosProfile, that one of the parent DdsCpServiceInstance is used.

[TPS_SYST_03095] DDS Event QoSProfile ⌈If present, the DdsCpQosProfile referenced in the role DdsCpServiceInstanceEvent.ddsEventQosProfile shall be used to identify the QoS policy configuration that applies to the single DdsCpServiceInstanceEvent. If not present, the DdsCpServiceInstance.ddsServiceQosProfile shall be used.⌋

6.7.5.6.16.1 DDS Provided Service Instances

The DdsCpProvidedServiceInstance is used to define a DDS Service provider. This meta-class represents the ability to describe the existence and configuration of a provided service instance in a concrete implementation on top of DDS.

6.7.5.6.16.2 DDS Consumed Service Instances

The DdsCpConsumedServiceInstance is used to define a DDS Service provider. This meta-class represents the ability to describe the existence and configuration of a required service instance in a concrete implementation on top of DDS.

6.7.5.7 StaticSocketConnection

Currently only the SOME/IP data communication that is subject to Service Discovery is described with ProvidedServiceInstances and ConsumedServiceInstances as mentioned in chapter 6.7.5.3.1.

But there is also the need to describe data exchange between two SocketAddresses where the SOME/IP Service Discovery protocol is not used. This may include for example the exchange of NM Data (see 6.7.5.9), DoIP data (see 6.7.5.10), SOME/IP Service Discovery messages (see 6.7.5.8), DDS data (see 6.7.5.6) and DDS Services (see 6.7.5.6.16).

Note: Differently from SOME/IP, for Service oriented communication on DDS the definition of DdsCpProvidedServiceInstances and DdsCpConsumedServiceInstances is needed also for complete static configuration, so also in this case StaticSocketConnections shall be used.

But also the data exchange that is not serialized according to the SOME/IP rules may be exchanged via the so called StaticSocketConnections. And even the exchange of SOME/IP serialized data which transmission is not subject to Service Discovery may be described with StaticSocketConnections. In this case the ServiceId and MessageId can be derived from the headerId of the SoConIPduIdentifier. If such SOME/IP serialized data exchange is described via a StaticSocketConnection then the definition of ProvidedServiceInstances and ConsumedServiceInstances does not need to be defined for this data exchange since Service Discovery is not used and all necessary information for the configuration of the COM Stack is available in the StaticSocketConnection itself and in the referenced SoConIPduIdentifiers.

[TPS_SYST_02251] Data exchange not regulated by the Service Discovery protocol between two communication endpoints ⌈Data exchange that is NOT subject to Service Discovery between two SocketAddresses is described with the StaticSocketConnection element that is aggregated by a SocketAddress in the role staticSocketConnection. The aggregating SocketAddress describes one communication endpoint. The referenced StaticSocketConnection.remoteAddress defines the second communication endpoint.⌋

Class	**StaticSocketConnection**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Ethernet::ServiceInstances			
Note	Definition of static SocketConnection between the Socket that is defined by the aggregating Socket Address and the remoteAddress.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SocketAddress.staticSocketConnection			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
iPduIdentifier	SoConIPduIdentifier	*	ref	Assignment of IPduIdentifiers that are transmitted over the static SocketConnection. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=iPduIdentifier.soConIPduIdentifier, iPdu Identifier.variationPoint.shortLabel vh.latestBindingTime=postBuild
remoteAddress	SocketAddress	0..1	ref	RemoteAddress of the static SocketConnection. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=remoteAddress.socketAddress, remote Address.variationPoint.shortLabel vh.latestBindingTime=postBuild
tcpConnect Timeout	TimeValue	0..1	attr	Specifies the time in seconds how long TCP connect attempts are repeated to reach SOAD_SOCON_ONLINE. This attribute is restricted to socket connection groups which are initiating a TCP connection and are under control of SoAd.
tcpRole	TcpRoleEnum	0..1	attr	Defines whether the local Address (that is aggregating the StaticSocketConnection) does a listen or a connect.

Table 6.202: StaticSocketConnection

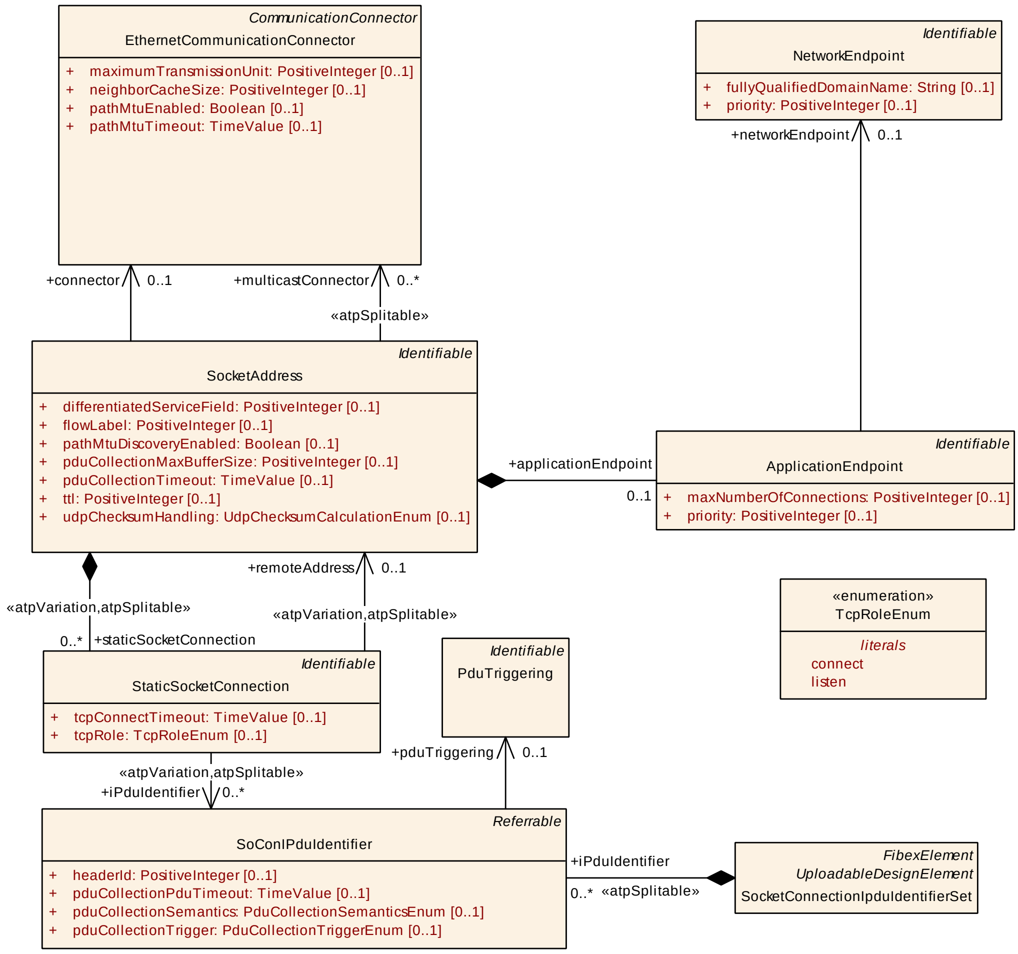

Figure 6.58: Model of StaticSocketConnection

UDP doesn't establish a connection before sending data, it is Connectionless. TCP on the other hand establishes a TCP connection. The client initiates the TCP communication and therefore it needs to be configured which endpoint acts as client and which acts as server.

[TPS_SYST_02252] Description of a TCP Client ⌈The SocketAddress that aggregates the StaticSocketConnection with tcpRole set to connect defines the TCP client.⌋

[TPS_SYST_02253] Description of a TCP Server ⌈The SocketAddress that aggregates the StaticSocketConnection with tcpRole set to listen defines the TCP server.⌋

[constr_5091] Relevance of tcpRole attribute

Imposition time: IT_SysDesc

⌈The attribute tcpRole shall only exist if the StaticSocketConnection is aggregated by a SocketAddress that defines a TCP Port in the aggregated ApplicationEndpoint.⌋

[constr_5092] Local and remoteAddress of a StaticSocketConnection shall define the same transport protocol

Imposition time: IT_SysDesc

⌈The transport protocol that is defined by the SocketAddress that aggregates the StaticSocketConnection shall be the same in the SocketAddress that is referenced by the same StaticSocketConnection in the role remoteAddress.⌋

[TPS_SYST_02254] Pdus transported over the StaticSocketConnection ⌈A Pdu that is transported over the StaticSocketConnection is described by SoConIPduIdentifier that is referenced in the role iPduIdentifier.⌋

Please note that the remoteAddress is allowed to be defined as ANY (TpPort = 0 and ipv4address/ipv6address = ANY). In other words the remote port and/or remote IP address is configured at runtime and the ECU is able to receive all packets that are addressed to its local address no matter what the remote address is.

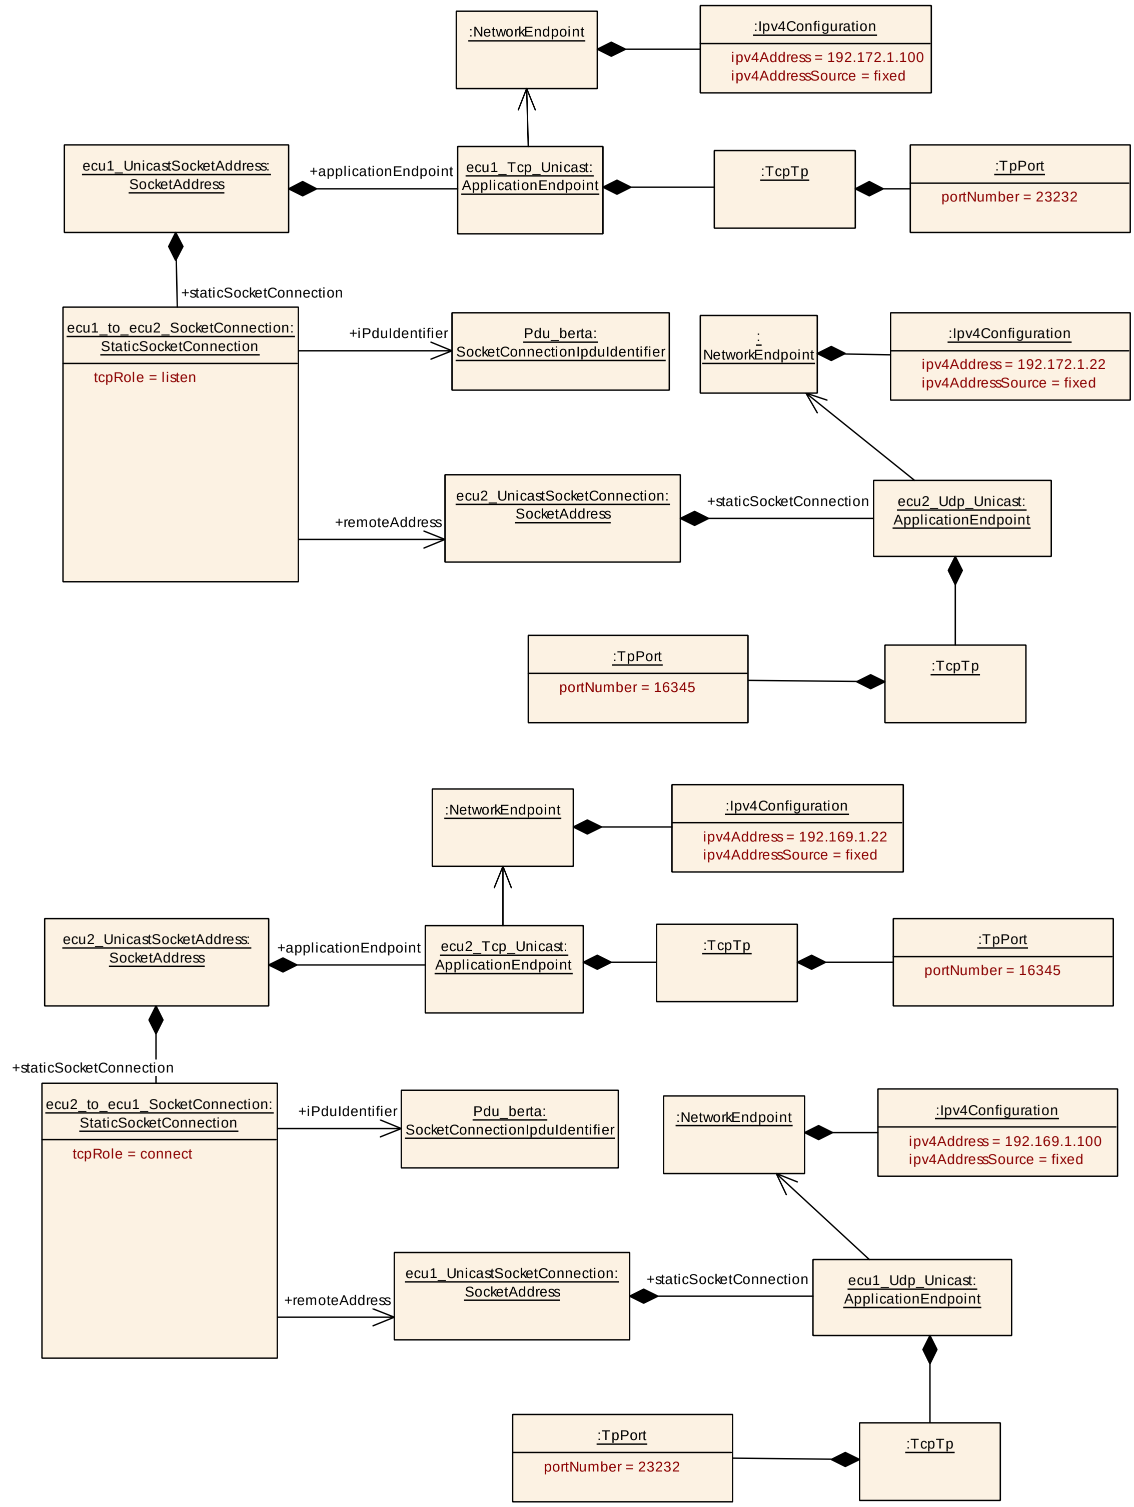

Figure 6.59: Example for the modeling of TCP StaticSocketConnections in TCP server role and TCP client role

The example in Figure 6.59 shows a `StaticSocketConnection` with the name *ecu2_to_ecu1_SocketConnection* on *ecu1_UnicastSocketAddress* that defines the TCP server. The socket connection is established to to *ecu2_UnicastSocketAddress* `remoteAddress`.

It also shows the StaticSocketConnection with the name *ecu1_to_ecu2_SocketConnection* on *ecu2_UnicastSocketAddress* that defines the TCP client. The socket connection is established to the *ecu1_UnicastSocketAddress* remoteAddress.

6.7.5.8 Service Discovery Message Configuration

If Service Discovery is used a Service Discovery Instance is configurable on an EcuInstance for a certain VLAN using the respective ApplicationEndpoint. The Service Discovery Instance refers to the configuration of a Service Discovery for a VLAN.

[TPS_SYST_02411] Rules for the creation of references to IPduPorts from PduTriggerings related to GeneralPurposePdus with category SD that are transmitted by an EcuInstance ⌈For each GeneralPurposePdu with category SD that is transmitted by an EcuInstance over IP unicast or IP multicast a PduTriggering needs to be defined on the EthernetPhysicalChannel (VLAN) that is referenced from the CommunicationConnector of the EcuInstance on which the Service Discovery Instance is configured:

- the PduTriggering for the Tx GeneralPurposePdu references the IPduPort with communicationDirection out of the EcuInstance

⌋

[TPS_SYST_02412] Rules for the creation of references to IPduPorts from PduTriggerings related to GeneralPurposePdus with category SD that are received via IP unicast by an EcuInstance ⌈For each GeneralPurposePdu with category SD that is received by an EcuInstance over IP unicast, a PduTriggering needs to be defined on the EthernetPhysicalChannel (VLAN) that is referenced from the CommunicationConnector of the EcuInstance on which the Service Discovery Instance is configured:

- the PduTriggering for the Rx GeneralPurposePdu references the IPduPort with communicationDirection in of the EcuInstance

⌋

[TPS_SYST_02413] Rules for the creation of references to IPduPorts from PduTriggerings related to GeneralPurposePdus with category SD that are received via IP mutlicast by an EcuInstance ⌈For each GeneralPurposePdu with category SD that is received by an EcuInstance over IP multicast, a PduTriggering needs to be defined on the EthernetPhysicalChannel (VLAN) that is referenced from the CommunicationConnector of the EcuInstance on which the Service Discovery Instance is configured:

- the PduTriggering for the Rx GeneralPurposePdu references the IPduPort with communicationDirection in of the EcuInstance

⌋

[TPS_SYST_02414] StaticSocketConnection for IP unicast/IP multicast transmission and IP unicast reception of GeneralPurposePdus with category SD ⌈A UDP Socket is used for transmission and reception of SD messages using a local unicast address. One StaticSocketConnection shall be created for each EcuInstance that participates in the SD message exchange to define:

- IP unicast transmission of SD messages (SubscribeEventGroup, StopSubscribeEventGroup, SubscribeEventGroupAck) by the EcuInstance
- IP unicast reception of SD messages (SubscribeEventGroup, StopSubscribeEventGroup, SubscribeEventGroupAck) by the EcuInstance
- IP multicast transmission of SD messages (OfferService, StopOfferService, FindService) by the EcuInstance

The PduTriggering that is defined in [TPS_SYST_02411] for transmitted GeneralPurposePdu and the PduTriggering for received GeneralPurposePdu that is defined in [TPS_SYST_02412] shall be assigned to the StaticSocketConnection via SoConIPduIdentifier. The StaticSocketConnection shall be aggregated on the local unicast SocketAddress of the EcuInstance.⌋

[TPS_SYST_02415] StaticSocketConnection for IP multicast reception of GeneralPurposePdus with category SD ⌈A UDP Socket is used for reception of SD messages using a local multicast address. One StaticSocketConnection shall be created for each EcuInstance that participates in the SD message exchange to define:

- IP multicast reception of SD messages (OfferService, StopOfferService, FindService) by the EcuInstance

The PduTriggering for the received GeneralPurposePdus that is defined in [TPS_SYST_02413] shall be assigned to the StaticSocketConnection via SoConIPduIdentifier. The StaticSocketConnection shall be aggregated on the multicast SocketAddress over which the EcuInstance receives the SD messages.⌋

[TPS_SYST_02117] Length of GeneralPurposePdu with category SD ⌈The length attribute for GeneralPurposePdus with category = SD shall be set to at most EthernetCommunicationConnector.maximumTransmissionUnit minus the sum of the length of the following headers:

- IP Header (for IpV4: 20 bytes, for IpV6: 40 bytes)
- IpV4 and IpV6 : any optional additional headers, e.g. for IPSec
- Udp Header (8 bytes)

- Socket Adaptor PDU Header (8 bytes)

⌋

[TPS_SYST_02118] Rules for the creation of references to IPduPorts from PduTriggerings related to GeneralPurposePdus with category SD ⌈For each GeneralPurposePdu with category SD a PduTriggering needs to be defined on the EthernetPhysicalChannel (VLAN) that is referenced from the CommunicationConnector of the EcuInstance on which the Service Discovery Instance is configured:

- the PduTriggering for the Tx GeneralPurposePdu references the OUT IPduPort of the EcuInstance
- the PduTriggering for the Rx GeneralPurposePdu (unicast reception) references the IN IPduPort of the EcuInstance
- the PduTriggering for the Rx GeneralPurposePdu (multicast reception) references the IN IPduPort of the EcuInstance

⌋

[constr_3267] PduTriggerings in Service Discovery StaticSocketConnections

Imposition time: IT_SysDesc

⌈SD StaticSocketConnections defined according to [TPS_SYST_02414] and [TPS_SYST_02415] shall only refer to PduTriggerings which point to GeneralPurposePdus of category SD.⌋

[constr_3268] Service Discovery StaticSocketConnection aggregation by a SocketAddress

Imposition time: IT_SysDesc

[constr_3273] Service Discovery multicast StaticSocketConnection's aggregation by an ApplicationEndpoint

Imposition time: IT_SysDesc

⌈The SD StaticSocketConnection for multicast defined in [TPS_SYST_02415] shall be aggregated by an ApplicationEndpoint that points to a NetworkEndpoint that defines an IP Multicast Address.⌋

[constr_3274] Service Discovery unicast StaticSocketConnection's aggregation by an ApplicationEndpoint

Imposition time: IT_SysDesc

⌈The SD StaticSocketConnection for unicast defined in [TPS_SYST_02414] shall be aggregated by an ApplicationEndpoint that points to a NetworkEndpoint that defines an IP Unicast Address.⌋

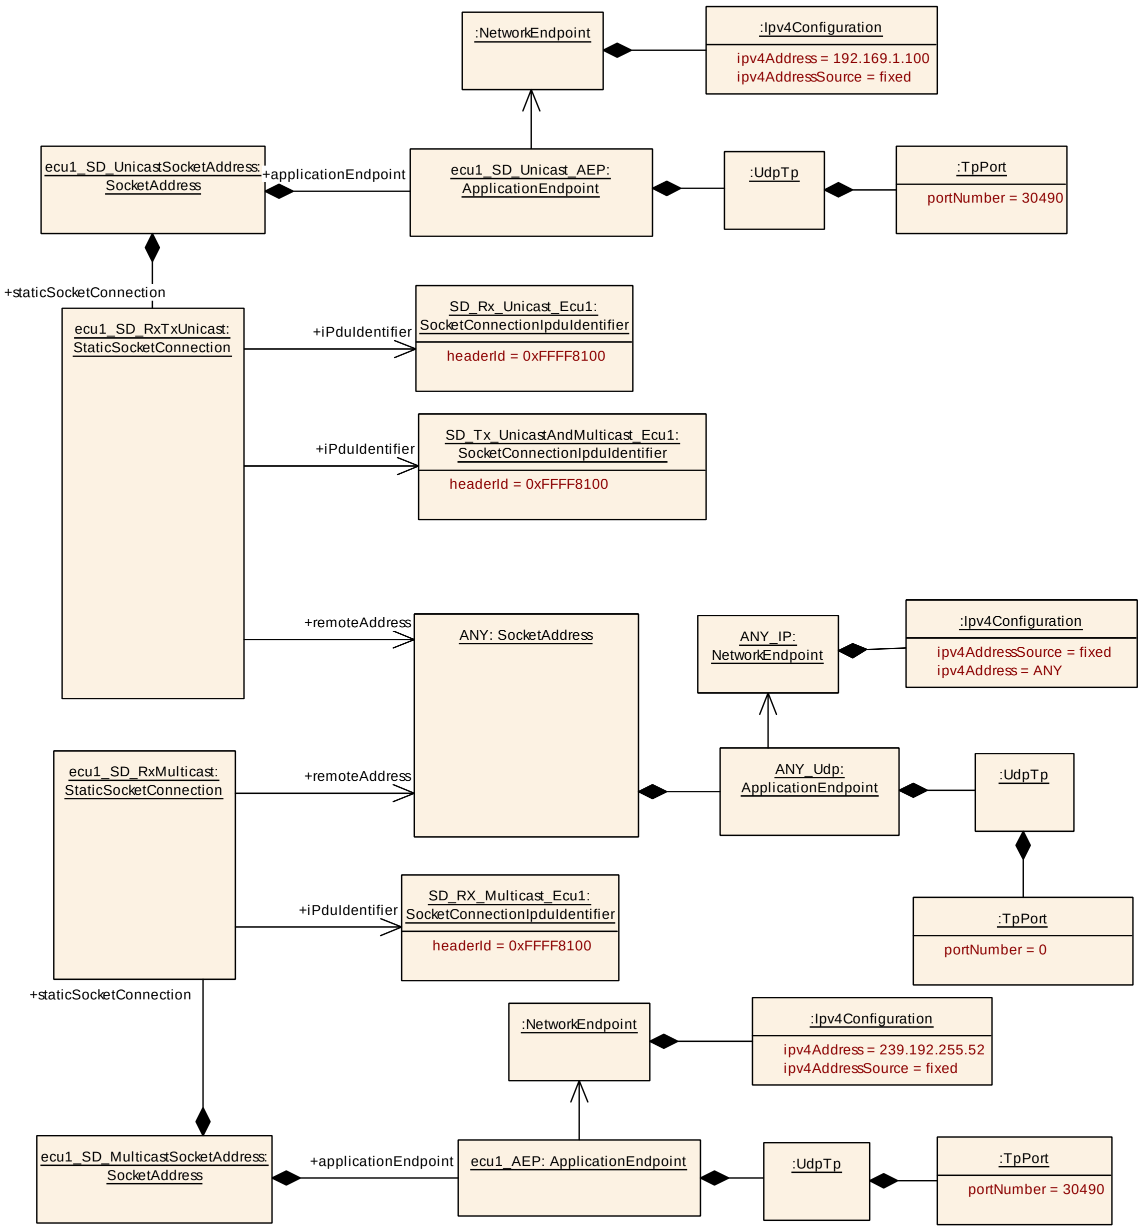

Figure 6.60: Example for the modeling of SD StaticSocketConnections

6.7.5.9 NmPdu data exchange over StaticSocketConnection

The data exchange of `NmPdu` on an Ethernet channel is described with the `StaticSocketConnection` as defined in chapter 6.7.5.7.

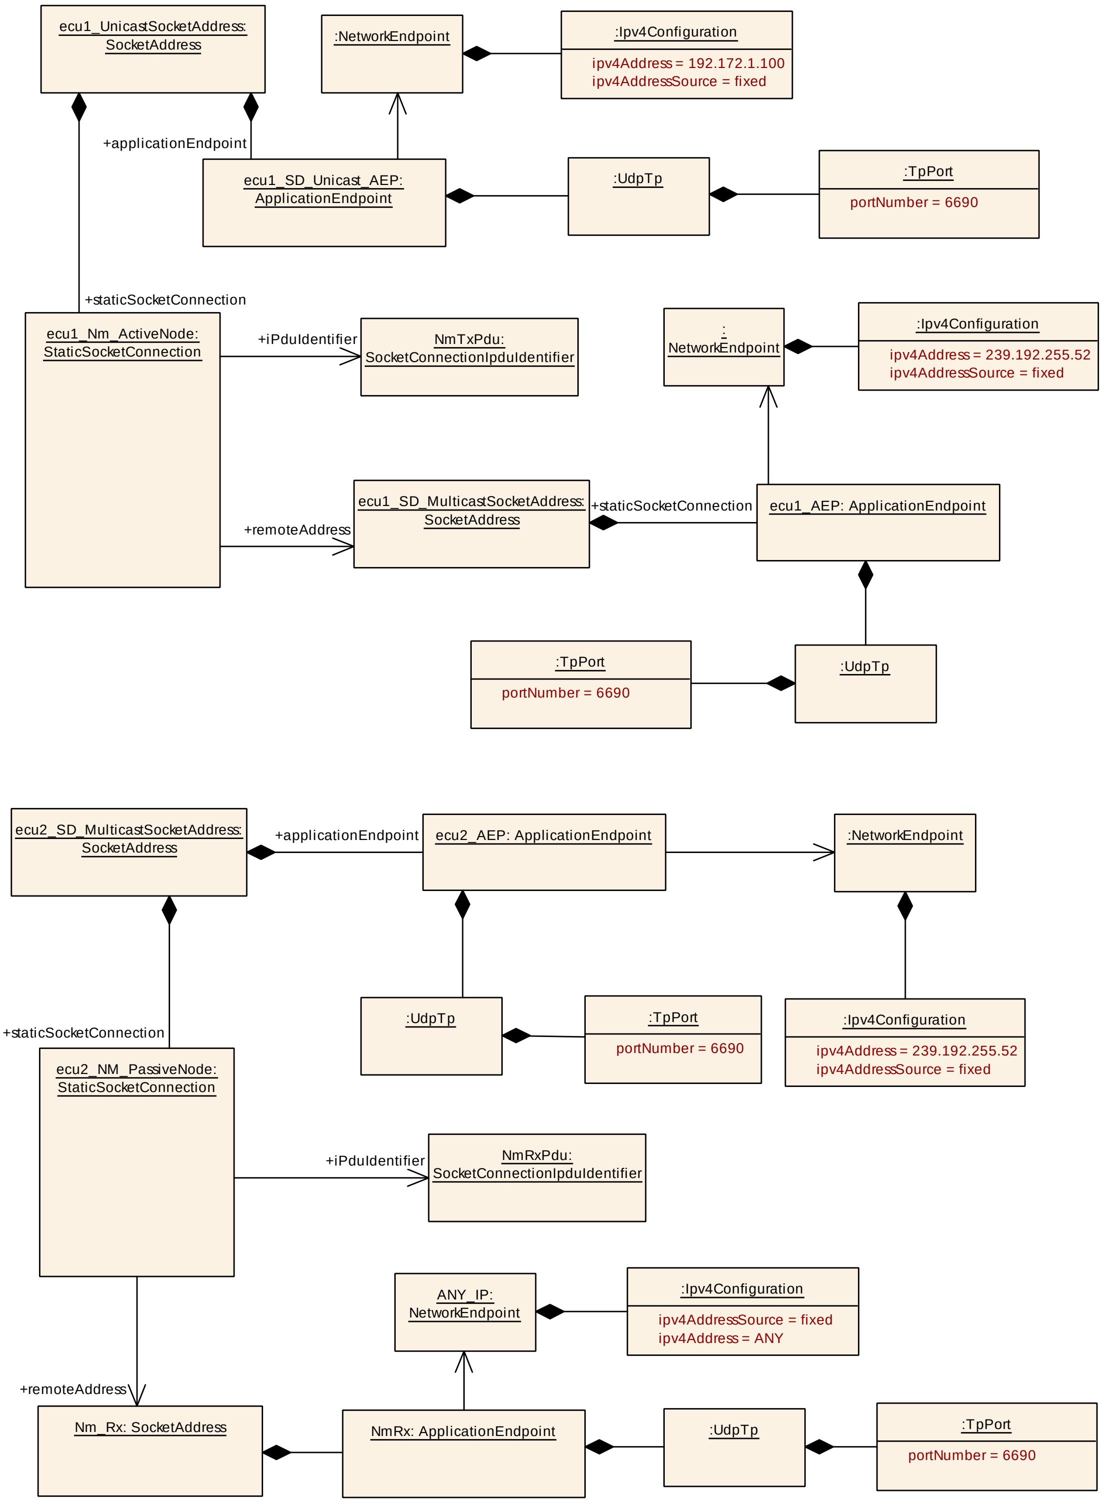

Figure 6.61: Example for the modeling of NM StaticSocketConnections

The example in Figure 6.61 shows a possible configuration where the active NmNode sends the NmPdu to a remote multicast address. Each passive and active NmNode receives the NmPdu over a local multicast address from all other nodes (remote Address = ANY).

6.7.5.10 Diagnostics over IP

DoIpConfig defines a DoIP module configuration for a specific EcuInstance. DoIP supports the communication of internal testers and external testers with an ECU/DoIP Node. Each DoIP node might define several logical DoIpInterfaces that may share the same physical Ethernet interface/MAC Address. The DoIP node is able to communicate on each of its DoIpInterfaces independently. I.e. the DoIP functionalities on each DoIpInterface are isolated from each other.

More details about DoIpInterfaces can be found in AUTOSAR_SWS_DiagnosticOverIP [28].

Class	**DoIpConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::DoIP			
Note	This element defines the DoIp configuration for a specific Ecu.			
Base	*ARObject*			
Aggregated by	EcuInstance.doIpConfig			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
doipInterface	DoIpInterface	*	aggr	DoIP node consists of one or several DoIPInterfaces over which the ECU is able to communicate via DoIP independently. I.e. DoIP functionalities on each IP interface are isolated from each other.
doIpProtocol Version	PositiveInteger	0..1	attr	Configures the DoIP protocol version used in the generic DoIP header. The valid range of this parameter is defined by the always latest release of ISO 13400-2 and can be extended with every new release of the ISO document. As example a value of 0x03 defines the ISO 13400-2:2019 release.
logicAddress	DoIpLogicAddress	0..1	aggr	Describes the logical address of the DoIP entity, i.e. the Local Address that will route diagnostic requests to the Dcm of the DoIP entity.

Table 6.203: DoIpConfig

Class	**DoIpInterface**			
Package	M2::AUTOSARTemplates::SystemTemplate::DoIP			
Note	A logical interface over which the DoIP Node is able to communicate via DoIP independently from other existing DoIpInterfaces.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	DoIpConfig.doipInterface			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
aliveCheck Response Timeout	TimeValue	0..1	attr	This attribute defines the timeout in seconds for waiting for response to an Alive Check request before the connection is considered to be disconnected. Represents parameter T_TCP_AliveCheck of ISO 13400-2:2012.
doipChannel Collection	DoIpTpConfig	0..1	ref	Configuration of DoIPChannels available in an DoIp Interface. Each DoIPChannel describes a connection between a doIpSourceAddress and a doIpTargetAddress and the exchange of DcmIPdus between the PduR and DoIP. A DoIP channel is constituted by the set of all DoIp TpConnection elements via which the configured Ecu Instance sends or receives SDUs that are sharing the same local diagnosis address and tester address.

▽

△

Class	**DoIpInterface**			
doipConnection	SocketConnection Bundle	*	ref	DoIP Connections in the DoIpInterface that define the Do IP Pdus that are sent and received via SoAd over TCP or UDP. **Tags:** atp.Status=obsolete
doIpRouting Activation	DoIpRoutingActivation	*	aggr	Collection of DoIpRoutingActivation possibilities defined in the DoIpInterface.
generalInactivity Time	TimeValue	0..1	attr	This attribute defines the timeout in seconds for maximum inactivity of a TCP socket connection before the DoIP module will close the according socket connection. Represents parameter T_TCP_General_Inactivity of ISO 13400-2:2012
initialInactivity Time	TimeValue	0..1	attr	This attribute defines the timeout in seconds used for initial inactivity of a connected TCP socket connection directly after socket connection. Represents parameter T_TCP_Initial_Inactivity of ISO 13400-2:2012
initialVehicle Announcement Time	TimeValue	0..1	attr	This attribute defines the waiting time in seconds for sending first vehicle announcement message after IP address assignment. Represents parameter A_DoIP_ Announce_Wait of ISO 13400-2:2012
isActivationLine Dependent	Boolean	0..1	attr	This attribute defines whether the network interface • is started "on-demand" when an activation line is sensed or • is always available.
maxTester Connections	PositiveInteger	0..1	attr	Maximum amount of tester connections that shall be maintained at one time before alive check is performed.
socket Connection	StaticSocketConnection	*	ref	DoIP Connections in the DoIpInterface that define the Do IP Pdus that are sent and received via SoAd over TCP or UDP.
useMacAddress ForIdentification	Boolean	0..1	attr	This attribute defines whether a configured EID at vehicle identification response/vehicle announcement is used or the MAC address. TRUE: Use MAC Address instead of EID for Vehicle identification/announcement. FALSE: Use configured EID for vehicle identification/announcement.
useVehicle Identification SyncStatus	Boolean	0..1	attr	This attribute defines if the optional VIN/GID synchronization status is used additionally in the vehicle identification/announcement.
vehicle Announcement Count	PositiveInteger	0..1	attr	This attribute defines the number of vehicle announcement messages on IP address assignment. Represents parameter A_DoIP_Announce_Num of ISO 13400-2:2012.
vehicle Announcement Interval	TimeValue	0..1	attr	This attribute defines the waiting time in seconds for sending subsequent vehicle announcement messages. Represents parameter A_DoIP_Announce_Interval of ISO 13400-2:2012

Table 6.204: DoIpInterface

Class	**DoIpRoutingActivation**
Package	M2::AUTOSARTemplates::SystemTemplate::DoIP
Note	This meta-class defines a DoIP routing activation possibility that activates the routing to the referenced doIPTargetAddress. This means that the diagnostic request messages related to the specified do IPTargetAddress received by socketConnections that are referenced by the same DoIpInterface that aggregates this DoIpRoutingActivation are activated.
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*

▽

Class	DoIpRoutingActivation			
Aggregated by	DoIpInterface.doIpRoutingActivation			
Attribute	Type	Mult.	Kind	Note
doIpTarget Address	DoIpLogicTarget AddressProps	*	ref	Reference to DoIPTargetAddress which is activated on this DoIpRoutingActivation.

Table 6.205: DoIpRoutingActivation

The DoIpInterface defines DoIpChannels with the doipChannelCollection reference that points to a DoIpTpConfig element that collects a number of DoIpTpConnections.

DoIpTpConnection describes a unidirectional connection between a doIpSourceAddress and a doIpTargetAddress and the exchange of a DcmIPdu that is defined with the tpSdu between the PduR and DoIP. The DiagnosticConnection with references to the DoIpTpConnection defines the related request and response messages.

A DoIpChannel in the Ecu configuration is constituted by the set of all DoIpTpConnection elements via which the EcuInstance that aggregates the DoIpConfig that references the DoIpTpConnection via the DoIpInterface sends or receives tpSdus that share the same local diagnosis address and tester address.

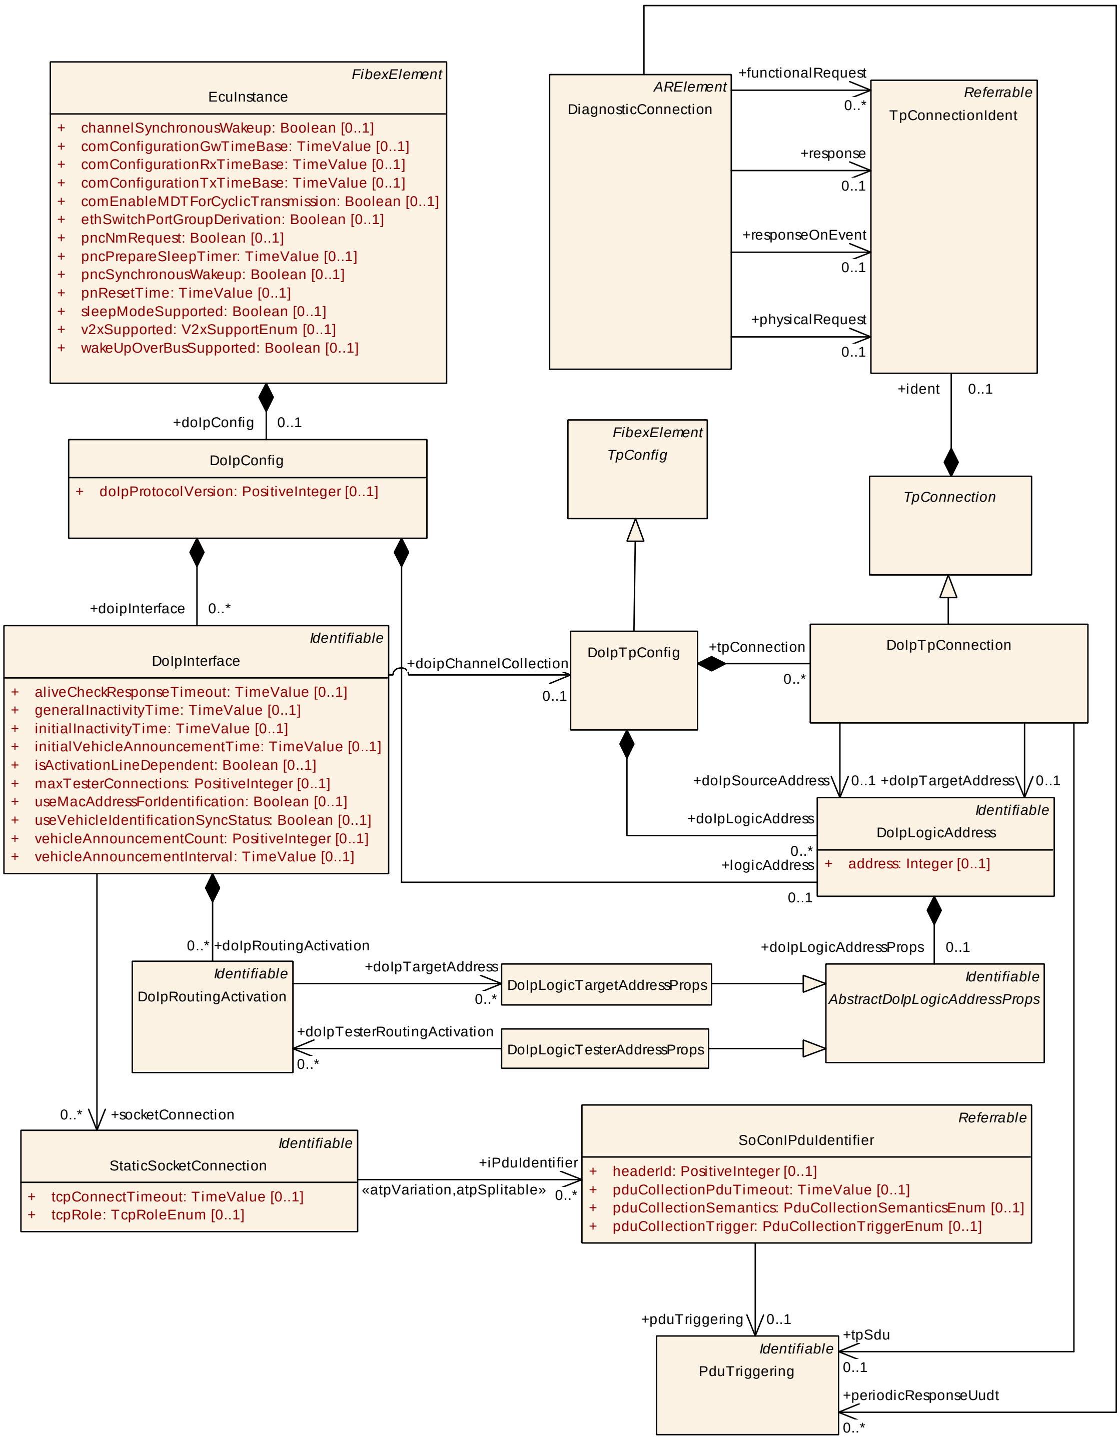

Figure 6.62: DoIP

Diagnostic messages are passed from a tester, through a DoIP gateway to the internal vehicle network. Before this happens the routing on a socket in the DoIP gateway needs to be activated. The tester sends a routing activation request and the DoIP entity responds to it. After the routing is activated the diagnostic communication starts.

[TPS_SYST_02303] Modeling of DoIpRoutingActivations ⌈The DoIP routing activation possibilities in a DoIpInterface are described by the DoIpRoutingActivation that is aggregated in the role doIpRoutingActivation in the DoIpInterface.⌋

[constr_3212] Limitation of DoIpTpConnection.tpSdu

Imposition time: IT_SysDesc

⌈DoIpTpConnection shall only reference PduTriggerings of DcmIPdus or UserDefinedIPdus in the role tpSdu.⌋

The diagnostic data is routed from the DoIP module to SoAd and back. The communication of diagnostic data over IP is described with StaticSocketConnections that contain SoConIPduIdentifiers with references to PduTriggerings of GeneralPurposePdus of category DoIP.

Please note that there is no connection between GeneralPurposePdus of category DoIP and the DoIpTpConnection in the System Description. The DoIP module evaluates the header of an incoming GeneralPurposePdu and knows from the included information the further processing.

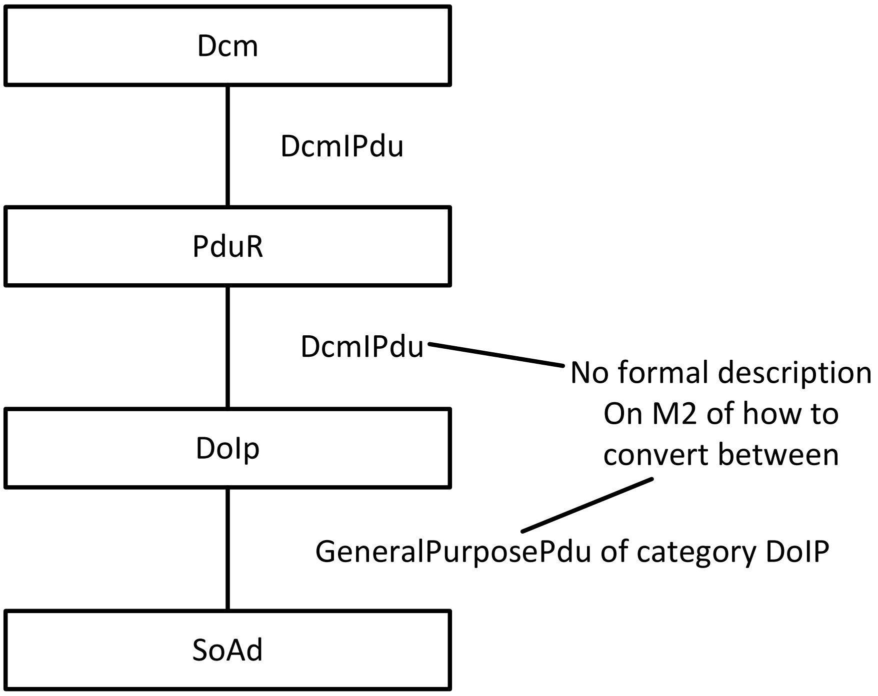

Figure 6.63: Routing of Dcm Pdus in AUTOSAR Stack for communication over IP

The `DoIpInterface.socketConnection` defines which `StaticSocketConnection` belongs to which `DoIpInterface`.

6.7.5.11 Transport Layer Security

AUTOSAR supports the configuration of *Transport Layer Security* for the information exchange between two *sockets*[2] that are modeled as `ApplicationEndpoint`s.

Please note that currently the DTLS (***Datagram*** *Transport Layer Security*) variant is not supported on the *AUTOSAR classic platform*.

It is a common use case that only one end of a TLS-based connection is actually modeled in an AUTOSAR model. The other end may exist off-board, e.g. as a diagnostic tester.

It is therefore important that the modeling does not rely on or imply knowledge about both ends of such a TLS-based connection.

An AUTOSAR model that only describes one end of the communication is positively required to work, independently of the availability of a formal modeling of the other end.

AUTOSAR provides two alternatives for modeling TLS in System Models:

[2]TLS connections are - by design - limited to a 1:1 pattern. A 1:n or n:1 communication pattern is not supported by TLS

- Modeling using `CryptoServicePrimitive`s (see section 6.7.5.11.1)
- Modeling using IANA [29] Parameters (see section 6.7.5.11.2).

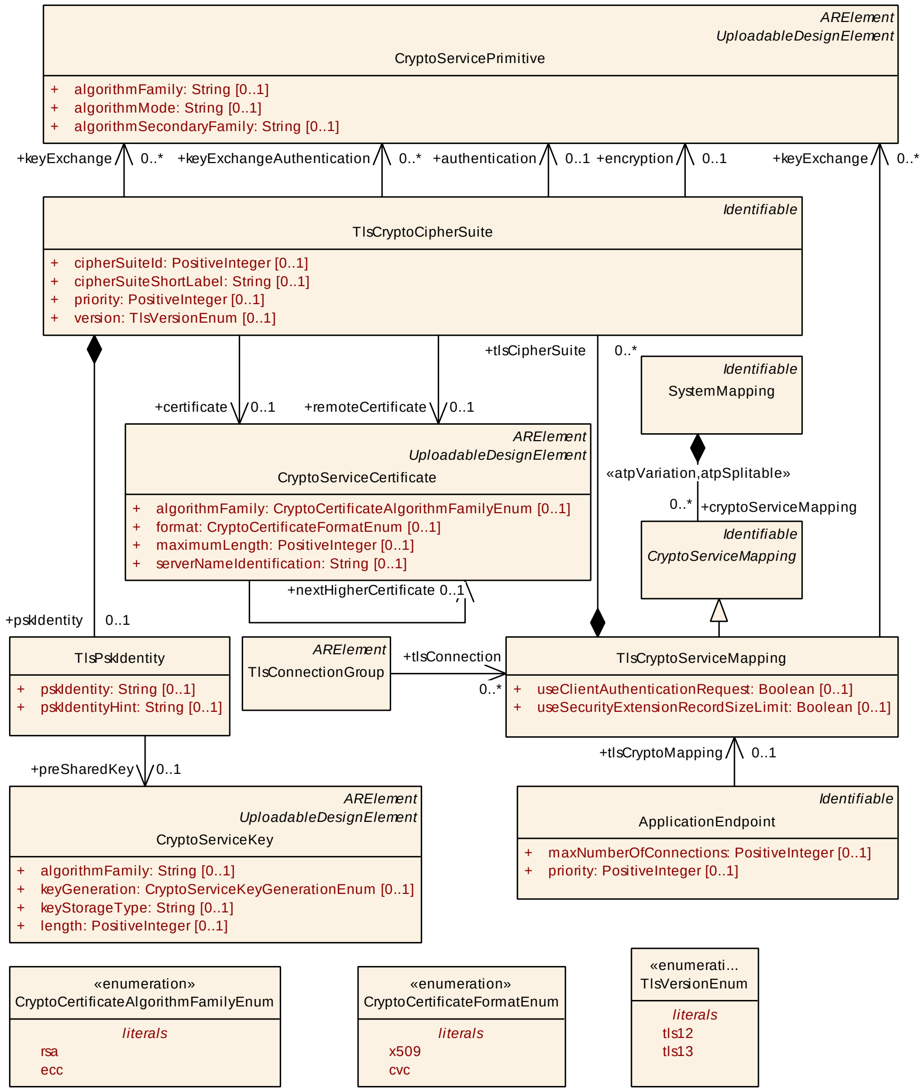

Figure 6.64: Modeling of crypto infrastructure for *Transport Layer Security*

Class	**TlsCryptoServiceMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This meta-class has the ability to represent a crypto service mapping for the socket-based configuration of Transport Layer Security (TLS).

Attribute	*Type*	*Mult.*	*Kind*	*Note*
keyExchange	CryptoServicePrimitive	*	ref	This reference identifies the shared(i.e. applicable for each of the aggregated cipher suites) crypto service primitive for the execution of key exchange during the handshake phase.

▽

△

Class	**TlsCryptoServiceMapping**			
tlsCipherSuite	TlsCryptoCipherSuite	*	aggr	This aggregation represents the collection of supported cipher suites.
useClient Authentication Request	Boolean	0..1	attr	Defines if client authentication shall be applied for this TLS connection.
useSecurity Extension RecordSize Limit	Boolean	0..1	attr	Defines if the security extension for max_fragment_length shall be supported as defined in IETF RFC 8449, chapter 4.1.

Table 6.212: TlsCryptoServiceMapping

The attribute TlsCryptoServiceMapping.useSecurityExtensionRecord-SizeLimit is defining the behavior for IETF RFC 8449 [30].

A TLS connection is established between two communication endpoints that assume the dedicated roles of *server* and *client*.

These roles cannot be swapped while the connection exists, i.e. a *server* remains the *server* for the full amount of time the connection exists.

[TPS_SYST_05029] Semantics of meta-class TlsCryptoServiceMapping ⌈As a sub-class of CryptoServiceMapping, meta-class TlsCryptoServiceMapping has the ability to collect the TLS-related configuration aspects from either the perspective of the *client* or the *server*.

In the case of TLS, the collection boils down to the aggregation of meta-class TlsCryptoCipherSuite in the role tlsCipherSuite plus the ability (by means of the role keyExchange) to define handshake properties that are shared for each of the aggregated tlsCipherSuites.⌋

[constr_1670] Prohibition of usage of tlsCryptoMapping in case of UDP socket connections

Imposition time: IT_SysDesc

⌈A TlsCryptoServiceMapping may only be referenced by an ApplicationEnd-point in the role tlsCryptoMapping if that ApplicationEndpoint aggregates a TcpTp in the role tpConfiguration.⌋

[constr_1671] Supported values of TlsCryptoServiceMapping.category

Imposition time: IT_SysDesc

⌈The only supported values of attribute TlsCryptoServiceMapping.category are:

- **TLS_SERVER**: the TlsCryptoServiceMapping assumes the role of the *server* in the TLS connection.

- **TLS_CLIENT**: the TlsCryptoServiceMapping assumes the role of the *client* in the TLS connection.

⌋

[constr_5319] TCP endpoint using TLS_SERVER role can only serve provided service instances

Imposition time: IT_SysDesc

⌈An ApplicationEndpoint that refers to TlsCryptoServiceMapping with category TLS_SERVER in the role tlsCryptoMapping is only allowed to be referenced by ProvidedServiceInstances in the role localUnicastAddress in case that the ProvidedServiceInstance does not have a remoteUnicastAddress defined.⌋

[constr_5320] TCP endpoint using TLS_CLIENT role can only serve consumed service instances

Imposition time: IT_SysDesc

⌈An ApplicationEndpoint that refers to TlsCryptoServiceMapping with category TLS_CLIENT in the role tlsCryptoMapping is only allowed to be referenced by ConsumedServiceInstances in the role localUnicastAddress in case that the ConsumedServiceInstance does not have a remoteUnicastAddress defined.⌋

The reason for [constr_5319] and [constr_5320] is that in the Service Discovery case the TLS *client* needs to establish the TLS connection and a TCP endpoint can only take one role: TLS_CLIENT or TLS_SERVER. If a TlsCryptoServiceMapping would act as TLS_CLIENT and would refer to a ProvidedServiceInstance then this TLS_CLIENT would need to establish the TLS connection. But in this case the TLS_CLIENT would not know to which remote service *client* a connection needs to be established since different ConsumedServiceInstances may directly call methods of the ProvidedServiceInstance without any registration.

The usage of a cipher suite in the context of setting up a TLS connection is formalized by means of meta-class TlsCryptoCipherSuite.

[TPS_SYST_05030] Semantics of TlsCryptoCipherSuite ⌈The creation of a TLS connection requires the usage of a suite of cryptographic operations in specific roles, also known as a *cipher suite*.

Meta-class TlsCryptoCipherSuite represents a given cipher suite for a TLS connection. TlsCryptoCipherSuite references meta-class CryptoServicePrimitive in three dedicated roles that represent the steps of the creation of a TLS connection.

More specifically, the cryptographic operations for setting up a TLS connection involve the following steps:

- **Key exchange**: these CryptoServicePrimitives may be used for the handshake phase of the TLS connection. Different alternatives exist for executing this phase and therefore the multiplicity of this reference is 0..*.
- **Authentication** of communication partners during the operational phase of the TLS connection. This part is similar to freshness calculation for SecOC-based communication. For this purpose a single CryptoServicePrimitive is used on each end of the communication.
- **Encryption** of content exchanged between the communication partners that have established the TLS connection. For this purpose a single CryptoServicePrimitive is used on each end of the communication.

⌋

Please note that according to TLS each TlsCryptoCipherSuite may support multiple PSKs or certificates. The model restricts the multiplicity of references from TlsCryptoCipherSuite to CryptoServiceCertificate and TlsPskIdentity to 0..1. A TLS configuration with multiple PSKs or Certificates per CipherSuite can be achieved by having multiple TlsCryptoCipherSuite's that share the same set of properties but reference different CryptoServiceCertificate's or TlsPskIdentity's, respectively.

Class	**TlsCryptoCipherSuite**			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This meta-class represents a cipher suite for describing cryptographic operations in the context of establishing a connection of ApplicationEndpoints that is protected by TLS.

Table 6.221: CryptoCertificateFormatEnum

[constr_1672] Existence of `TlsCryptoCipherSuite.certificate` and `TlsCryptoCipherSuite.pskIdentity` in the *server* role

Imposition time: `IT_SysDesc`

⌈**Either**

- the reference to `CryptoServiceCertificate` in the role `TlsCryptoCipherSuite.certificate`

- the aggregation of TlsPskIdentity in the role TlsCryptoCipherSuite.pskIdentity

shall exist if the TlsCryptoCipherSuite is aggregated by a TlsCryptoServiceMapping that has attribute category set to the value TLS_SERVER.⌋

In other words two different approaches are supported by TLS for the handling of key exchange: Pre-shared secret and certificate.

The *server* may optionally request a certificate from the *client*. If this option is not used then other documented approaches for completing the handshake phase are foreseen for the specific case.

[TPS_SYST_05033] Existence of TlsCryptoCipherSuite.certificate and TlsCryptoCipherSuite.pskIdentity in the *client* role ⌈The *client* (TlsCryptoServiceMapping has the attribute category set to the value TLS_CLIENT) has the following authentication options:

- the reference to CryptoServiceCertificate in the role TlsCryptoCipherSuite.certificate exists,
- the aggregation of TlsPskIdentity in the role TlsCryptoCipherSuite.pskIdentity exists,
- neither TlsCryptoCipherSuite.certificate nor TlsCryptoCipherSuite.pskIdentity exists and TlsCryptoServiceMapping.useClientAuthenticationRequest is set to *false*. In this case the handshake is provided on the basis of the *server* certificate only.

⌋

In the pre-shared Key approach the *client* indicates which key to use by including a pskIdentity in the ClientKeyExchange message. To help the *client* in selecting which identity to use, the *server* can provide a pskIdentityHint in the ServerKeyExchange message. Please note that the usage of pskIdentityHints is restricted for usage with TLS 1.2.

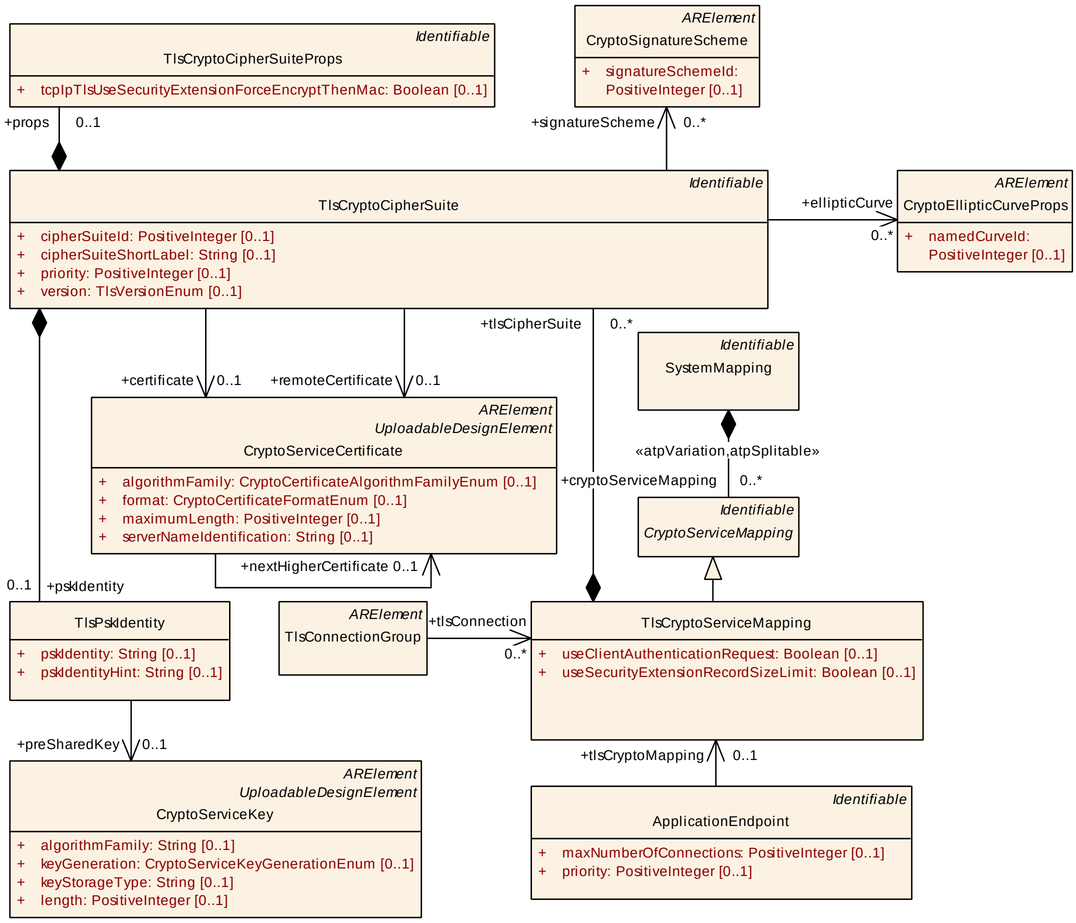

Figure 6.65: Modeling of crypto infrastructure for *Transport Layer Security*

AUTOSAR provides two alternatives for modeling TLS in System Models:

6.7.5.11.1 Modeling TLS using `CryptoServicePrimitive`s

Instances of `TlsCryptoServiceMapping` and `TlsCryptoCipherSuite` allow to refer to `CryptoServicePrimitive`s via

- `TlsCryptoServiceMapping.keyExchange`
- `TlsCryptoCipherSuite.keyExchange`
- `TlsCryptoCipherSuite.keyExchangeAuthentication`
- `TlsCryptoCipherSuite.authentication`
- `TlsCryptoCipherSuite.encryption`.

Setting up these references to `CryptoServicePrimitive`s with specific properties allows to define *how* a TLS Connection and its associated TLS cipher suites are working by defining the `CryptoServicePrimitive` they employ. Instances of the `CryptoServicePrimitive` class directly map to `CsmPrimitive` containers in the `Csm` configuration, which makes the translation into `Csm` configurations straightforward.

Using CryptoServicePrimitive elements for modeling TLS, however, makes it hard to infer *what* a TLS Connection and its associated TLS cipher suites are from the information *how* they work. It is, for instance, difficult to determine the IANA id [29] of a TLS cipher suite by examining the properties of the CryptoServicePrimitive elements the associated TlsCryptoCipherSuite is referencing.

Defining CryptoServicePrimitive elements couples the TLS configuration of the System Model tightly to the Csm module configuration which demands deep knowledge of the Csm for setting up the TLS part of the system model. Moreover, software suppliers might deviate from the Csm standard when it comes to the configuration of CsmPrimitive containers. As a consequence, two stack vendors might require differently configured CryptoServicePrimitive elements for modeling the same cipher suite.

For all these shortcomings, it is recommended to define TLS connections that use standard cipher suites by defining IANA parameters [29] instead of referencing to CryptoServicePrimitives . Defining CryptoServicePrimitives can be the solution to model non-standard cipher suites, however they still require custom support from vendors.

6.7.5.11.2 Modeling TLS using IANA Parameters

IANA provides a set of TLS Parameters [29] to specify the properties of standardized cipher suites, which are partly also available in the TLS part of AUTOSAR System Models:

- TlsCryptoCipherSuite.cipherSuiteId
- TlsCryptoCipherSuite.cipherSuiteShortLabel

and, if the cipher suite requires key exchange:

- CryptoEllipticCurveProps.namedCurveId
- CryptoSignatureScheme.signatureSchemeId.

The specification of these parameters defines *what* a TLS Connection and their cipher suites are in contrast to the first approach which defines *how* they operate. The specification of a standardized cipher suite allows to derive the CsmPrimitives required for its operation without tight coupling to the specifics of the Csm configuration.

[constr_3668] Existence of TlsCryptoCipherSuite.cipherSuiteShortLabel

Imposition time: IT_SysDesc

⌈If a TlsCryptoCipherSuite.cipherSuiteShortLabel is defined then:

- the attribute TlsCryptoCipherSuite.cipherSuiteId shall be defined as well

- the value of TlsCryptoCipherSuite.cipherSuiteShortLabel shall match the *Description* value corresponding to the *Value* field defined in TlsCryptoCipherSuite.cipherSuiteId according to TlsCryptoCipherSuite Parameter set defined in [29].

⌋

Common parameters:

The TLS part of the system model specifies a set of entities and parameters that can be configured in both alternatives. They allow the definition of certificates or pre-shared Keys which the cipher suites are using and the definition of extensions e.g. for increasing the security of a TLS connection:

- TlsCryptoCipherSuite.priority
- TlsCryptoCipherSuite.version
- TlsCryptoCipherSuite.pskIdentity
- TlsCryptoCipherSuite.certificate
- TlsCryptoCipherSuite.remoteCertificate
- TlsCryptoServiceMapping.useClientAuthenticationRequest
- TlsCryptoServiceMapping.useSecurityExtensionRecordSizeLimit
- All parameters specified in TlsCryptoCipherSuiteProps.

For Details on TlsCryptoCipherSuite.cipherSuiteId and TlsCryptoCipherSuite.cipherSuiteShortLabel see [29] section "TLS Cipher Suites".

For Details on CryptoEllipticCurveProps and namedCurveId see [29] section "TLS Supported Groups".

For Details on CryptoSignatureScheme and signatureSchemeId see [29] section "TLS SignatureScheme".

6.7.5.12 IPsec

IPsec is a protocol suite that provides cryptographic protection for IP datagrams in IPv4 and IPv6 network packets.

IPsec uses a security association to specify security properties that are shared between the communicating parties. The security association defines a relationship between two or more parties and determines which security services will be used to communicate securely. In other words the security association serves as a “contract” between the different devices.

A single security association protects data in one communication direction. Two security associations shall be present to secure traffic in both directions. Each security association can provide encryption, data integrity and data authentication.

In addition the senders and receivers of IP datagrams can determine the required protection for an IP packet according to IPsec security policies.

These are rules that define how datagrams are processed that are received by a device. For example, security policies are used to decide if a particular packet needs to be dropped or needs to be processed by IPsec.

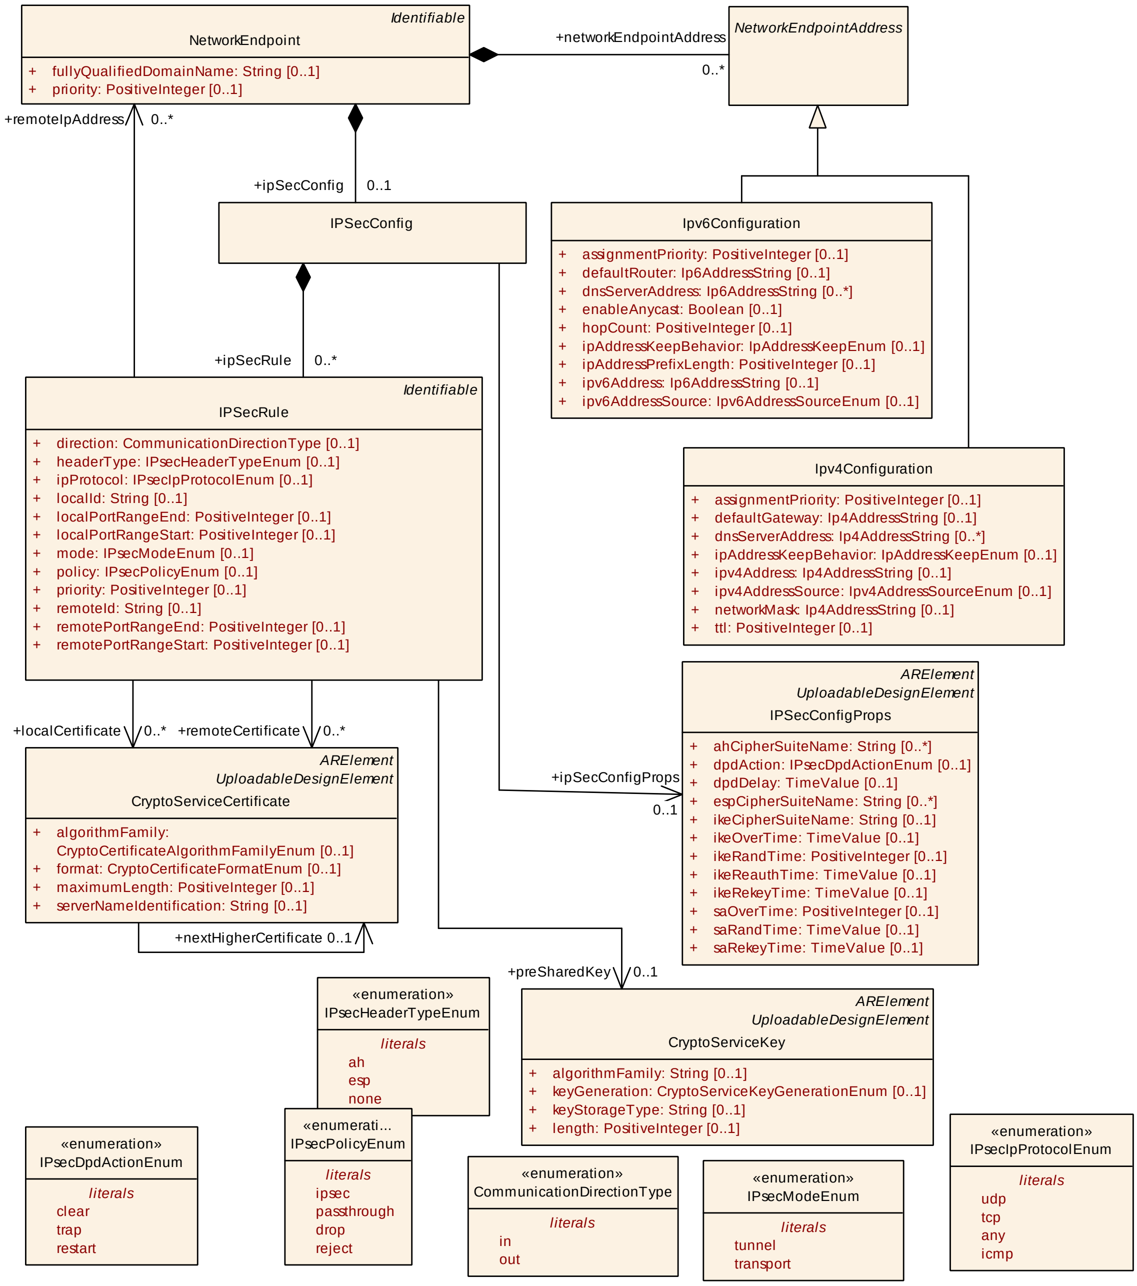

Figure 6.66: IPsec configuration model

[TPS_SYST_02265] Configuration of IPsec ⌈The `IPSecConfig` meta-class that is aggregated by a `NetworkEndpoint` in the role `ipSecConfig` provides the ability to define IPsec settings that are necessary to configure IPsec security associations and IPsec security policies.⌋

[TPS_SYST_02266] Definition of `IPSecRules` ⌈The `IPSecConfig` meta-class may contain one or several `IPSecRule`s. Each `IPSecRule` defines the network connection that is monitored by IPsec by defining the local endpoint and the remote endpoint. Each endpoint is defined by the IP Address and the Tcp/Udp Port. The communication direction for which the `IPSecRule` is valid is defined by the `direction` attribute.⌋

Class	**IPSecConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	IPsec is a protocol that is designed to provide "end-to-end" cryptographically-based security for IP network connections.			
Base	*ARObject*			
Aggregated by	NetworkEndpoint.ipSecConfig			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
ipSecConfigProps	IPSecConfigProps	0..1	ref	Global IPsec configuration settings that are valid for all IPSecRules that are defined on the NetworkEndpoint.
ipSecRule	IPSecRule	*	aggr	IPSec rules and filters that are defined in the IPSecConfig for a specific NetworkEndpoint.

Table 6.222: IPSecConfig

Class	**IPSecRule**			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This element defines an IPsec rule that describes communication traffic that is monitored, protected and filtered.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	IPSecConfig.ipSecRule			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
direction	CommunicationDirectionType	0..1	attr	This attribute defines the direction in which the traffic is monitored. If this attribute is not set a bidirectional traffic monitoring is assumed.
headerType	IPsecHeaderTypeEnum	0..1	attr	Header type specifying the IPsec security mechanism.
ipProtocol	IPsecIpProtocolEnum	0..1	attr	This attribute defines the relevant IP protocol used in the Security Policy Database (SPD) entry.
localCertificate	CryptoServiceCertificate	*	ref	This reference identifies the applicable certificate used for a local authentication.
localId	String	0..1	attr	This attribute defines how the local participant should be identified for authentication.

▽

△

Class	**IPSecRule**			
localPortRange End	PositiveInteger	0..1	attr	This attribute restricts the traffic monitoring and defines an end value for the local port range. If this attribute is not set then this rule shall be effective for all local ports. Please note that port ranges are currently not supported in the AUTOSAR AP's operating system backend. If AP systems are involved, each IPsec rule may only contain a single port.
localPortRange Start	PositiveInteger	0..1	attr	This attribute restricts the traffic monitoring and defines a start value for the local port range. If this attribute is not set then this rule shall be effective for all local ports. Please note that port ranges are currently not supported in the AUTOSAR AP's operating system backend. If AP systems are involved, each IPsec rule may only contain a single port.
mode	IPsecModeEnum	0..1	attr	This attribute defines the type of the connection.
policy	IPsecPolicyEnum	0..1	attr	An IPsec policy defines the rules that determine which type of IP traffic needs to be secured using IPsec and how that traffic is secured.
preSharedKey	CryptoServiceKey	0..1	ref	This reference identifies the applicable cryptograhic key used for authentication.
priority	PositiveInteger	0..1	attr	This attribute defines the priority of the IPSecRule (SPD entry). The processing of entries is based on priority, starting with the highest priority "0".
remote Certificate	CryptoService Certificate	*	ref	This reference identifies the applicable certificate used for a remote authentication.
remoteId	String	0..1	attr	This attribute defines how the remote participant should be identified for authentication.
remoteIp Address	NetworkEndpoint	*	ref	Definition of the remote NetworkEndpoint. With this reference the connection between the local Network Endpoint and the remote NetworkEndpoint is described on which the traffic is monitored.
remotePort RangeEnd	PositiveInteger	0..1	attr	This attribute restricts the traffic monitoring and defines an end value for the remote port range. If this attribute is not set then this rule shall be effective for all local ports. Please note that port ranges are currently not supported in the AUTOSAR AP's operating system backend. If AP systems are involved, each IPsec rule may only contain a single port.
remotePort RangeStart	PositiveInteger	0..1	attr	This attribute restricts the traffic monitoring and defines a start value for the remote port range. If this attribute is not set then this rule shall be effective for all local ports. Please note that port ranges are currently not supported in the AUTOSAR AP's operating system backend. If AP systems are involved, each IPsec rule may only contain a single port.

Table 6.223: IPSecRule

Class	IPSecConfigProps			
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication			
Note	This element holds all the attributes for configuration of IPsec that are independent of specific IPsec rules. **Tags:** atp.recommendedPackage=IPSecConfigProps			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *UploadableDesignElement*, *UploadablePackageElement*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
ahCipherSuiteName	String	*	attr	AH (Authentication Header) algorithm to be used for the connection, e.g. HMAC/SHA2-256
dpdAction	IPsecDpdActionEnum	0..1	attr	This attribute defines what to do if the peer is considered dead. If not configured "restart" shall be assumed.
dpdDelay	TimeValue	0..1	attr	This attribute describes the interval to check the liveness of a peer actively using IKEv2 INFORMATIONAL exchanges. Active DPD checking is only enforced if no IKE or ESP/AH packet has been received for the configured DPD delay. In not configured the value "5 minutes" shall be assumed.
espCipherSuiteName	String	*	attr	ESP (Encapsulating Security Payload) algorithm that provides encryption and optional authentication for the connection, e.g. AES-128+SHA2-256.
ikeCipherSuiteName	String	0..1	attr	IKE encryption/authentication algorithms to be used for the connection.
ikeOverTime	TimeValue	0..1	attr	This attribute describes the hard deadline when an SA becomes invalid in percentage. Example: ikeOverTime of max(ikeReauthTime, ikeRekeyTime). Default: 10 %
ikeRandTime	PositiveInteger	0..1	attr	This attribute defines in percentage by how long before the expiration of ikeReauthTime and ikeRekeyTime will be rekeyed/reauthenticated. Default: 10%
ikeReauthTime	TimeValue	0..1	attr	This attribute defines the absolute time after which an IKE SA will be reauthenticated. 0 means reauthentication is disabled.
ikeRekeyTime	TimeValue	0..1	attr	This attribute defines the absolute time after which an IKE SA will be rekeyed. 0 means rekey is disabled.
saOverTime	PositiveInteger	0..1	attr	This attribute describes the hard deadline when an IPsec SA becomes invalid in percentage. Example: saOverTime * saRekeyTime. Default: 110%
saRandTime	TimeValue	0..1	attr	This attribute defines by how long before the expiration of saRekeyTime will be rekeyed.
saRekeyTime	TimeValue	0..1	attr	This attribute defines the absolute time after which an IPsec SA will be rekeyed. 0 means rekey is disabled.

Table 6.224: IPSecConfigProps

Enumeration	**IPsecIpProtocolEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication

Aggregated by	IPSecRule.ipProtocol
Literal	*Description*
any	ANY protocol **Tags:** atp.EnumerationLiteralIndex=3
icmp	Internet Control Message Protocol (ICMP) **Tags:** atp.EnumerationLiteralIndex=2
tcp	TCP Protocol **Tags:** atp.EnumerationLiteralIndex=1
udp	UDP Protocol **Tags:** atp.EnumerationLiteralIndex=0

Table 6.225: IPsecIpProtocolEnum

[TPS_SYST_02270] Definition of general IPsec configuration settings ⌈General configuration properties that are independent of particular IPSecRules are collected in the IPSecConfigProps element that is referenced from the IPSecConfig in the role ipSecConfigProps.⌋

[TPS_SYST_02267] IPsec policy ⌈The IPSecRule.policy attribute defines how IP packets are handled that are going over the network connection defined by the IPSecRule. In detail it defines whether the IP packet is processed by IPsec or not.⌋

Enumeration	**IPsecPolicyEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication
Note	Defines the filter actions that are supported by IPsec.
Aggregated by	IPSecRule.policy
Literal	*Description*
drop	Signifying that packets should be discarded **Tags:** atp.EnumerationLiteralIndex=3
ipsec	Signifying that packets should be protected. **Tags:** atp.EnumerationLiteralIndex=1
passthrough	Signifying that no IPsec processing should be done at all. **Tags:** atp.EnumerationLiteralIndex=2
reject	Signifying that packets should be discarded and a diagnostic ICMP returned. **Tags:** atp.EnumerationLiteralIndex=4

Table 6.226: IPsecPolicyEnum

IPsec can be configured to operate in two different modes, Tunnel and Transport mode. With tunnel mode, the entire IP packet is protected by IPsec. IPsec wraps the original packet, encrypts it and adds a new IP header to it. The tunnel mode is most commonly used between VPN gateways and the IP addresses of the newly added outer IP header are that of the VPN Gateways. In other words the traffic between the two VPN Gateways is protected and each gateway acts as a proxy for the hosts behind it.

The transport mode provides the protection of the Data Payload of the IP datagram with an AH or ESP header. The IP Header remains the same and IPsec inserts its header between the IP header and the upper level headers. The IPsec transport mode can be used when securing traffic between two hosts or between a host and a VPN gateway.

[TPS_SYST_02268] IPsec mode ⌈The IPSecRule.mode attribute defines whether the IP packet is processed in the transport or tunnel mode.⌋

Please note that AUTOSAR currently supports only the transport mode as configuration option.

Enumeration	**IPsecModeEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication
Note	This enumeration describes the supported IPSec modes.
Aggregated by	IPSecRule.mode
Literal	***Description***
transport	Signifying that the IPSec transport mode is used. With the transport mode the original IP header is retained and only the IP payload and ESP trailer is encrypted. **Tags:** atp.EnumerationLiteralIndex=1
tunnel	Signifying that the IPSec tunnel mode is used. With tunnel mode, the entire original IP packet is protected by IPSec. This means IPSec wraps the original packet, encrypts it, adds a new IP header and sends it to the other side. **Tags:** atp.EnumerationLiteralIndex=0

Table 6.227: IPsecModeEnum

IPsec uses two protocols:

- AH - Authentication Header
- ESP - Encapsulating Security Payload

The AH protocol provides a mechanism for authentication only and authenticates the entire IP packet, including the outer IP header.

The ESP protocol provides data confidentiality (encryption) and/or authentication (data integrity, data origin authentication, and replay protection).

When ESP is used in transport mode, the IP payload is encrypted and the original IP header is moved to the front of the message. The ESP header is inserted after the IP header and is signed together with the IP payload. The original IP header remains unprotected.

When ESP is used in tunnel mode a new IP Header is created and the ESP header is added in front of the original IP Packet. The entire original IP packet is encrypted and signed in this mode.

[TPS_SYST_02269] IPsec AH and ESP protocol configuration ⌈In the IPSecRule it is possible to define the IPsec protocol that shall be used to protect IP packets that are going over the defined network connection. The attribute headerType defines whether AH, ESP or neither one is used.⌋

Enumeration	**IPsecHeaderTypeEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::SecureCommunication
Note	IPsec Header Type options
Aggregated by	IPSecRule.headerType
Literal	***Description***
ah	Authentication Header (AH) **Tags:** atp.EnumerationLiteralIndex=0
esp	Encapsulating Security Payloads (ESP) **Tags:** atp.EnumerationLiteralIndex=1
none	No header **Tags:** atp.EnumerationLiteralIndex=2

Table 6.228: IPsecHeaderTypeEnum

[TPS_SYST_02271] IPsec AH and ESP CipherSuites ⌈The attributes ahCipherSuiteName and espCipherSuiteName define the supported AH and ESP algorithms.⌋

The naming convention for ahCipherSuiteName, espCipherSuiteName and IPSecConfigProps.ikeCipherSuiteName shall follow the naming convention for cryptographic primitives that is defined in [31].

[TPS_SYST_02272] IPsec Internet Key Exchange protocol configuration ⌈In the IPSecRule it is possible to define how IKE protocol authenticates the remote party and how the local party authenticates itself to the remote party. In other words both sides use the same method. The usage of the IPSecRule.preSharedKey reference defines that the pre-shared key is used. The usage of the IPSecRule.localCertificate and IPSecRule.remoteCertificate defines that Digital Signature Authentication is used.⌋

[constr_5163] Existence of attribute IPSecRule.headerType

Imposition time: IT_SysDesc

⌈For each IPSecRule, the attribute headerType shall exist.⌋

[constr_5164] Existence of attribute IPSecRule.ipProtocol

Imposition time: IT_SysDesc

⌈For each IPSecRule, the attribute ipProtocol shall exist.⌋

[constr_5165] Existence of attribute IPSecRule.policy

Imposition time: IT_SysDesc

⌈For each IPSecRule, the attribute policy shall exist.⌋

Please note that the supported IKE CipherSuites are configured with the IPSecConfigProps.ikeCipherSuiteName. The IPSecConfigProps contains additional IKE specific configuration settings.

Enumeration	**IPsecDpdActionEnum**

6.7.5.14 Restriction in usage of ProvidedServiceInstance.majorVersion

If several ProvidedServiceInstances are defined with the same serviceIdentifier and different majorVersions and these ProvidedServiceInstances are referencing the same ApplicationEndpoint with the localUnicastAddress (ProvidedServiceInstances are located on the same Socket) then particular restrictions apply for the system configuration.

In such a scenario the same MessageId (headerId) may be used for ServiceInterface elements like an Event in the different ProvidedServiceInstances that have different majorVersions. It may happen that the same headerId is used for Pdus that represent the same ServiceInterface element even if the Pdu layout differs in the different MajorVersion ProvidedServiceInstances because for example the dataType of the Service Interface element was changed from one MajorVersion to the other.

The reason for these restrictions is the AUTOSAR Architecture in the Classic Platform where one part of the SOME/IP Header is evaluated in the SOME/IP Transformer (RequestId, Protocol Version, Interface Version, Message Type, Return Code) and the other part in the SocketAdaptor (MessageId, Length). This means that the Socket Adaptor is not able to evaluate the MajorVersion in the Pdu.

The following restrictions apply in case of **ClientServer communication** (Service Interface Methods, Field Getter, Field Setter): If two or more ProvidedServiceInstances are defined using the same serviceIdentifier and different majorVersions and these ProvidedServiceInstances are referencing the same ApplicationEndpoint via localUnicastAddress then the destination IP address, the destination port number, and the Level 4 protocol (Udp/Tcp) fields of header of IP packets containing call PDUs that are sent to the ProvidedServiceInstances are identical. In such a scenario, the ProvidedServiceInstances may still use identical method Ids (thus identical Header Ids) if the following condition applies:

At any point in time only one of the ProvidedServiceInstances is active, and only clients of that ProvidedServiceInstance send request PDUs to the ProvidedServiceInstance.

In all other cases, the method ids of the two ProvidedServiceInstances should not overlap.

The following restrictions apply in case of **SenderReceiver communication** (Service Interface Events and Notifier): If two or more ProvidedServiceInstances are defined using the same serviceIdentifier and different majorVersions, and these ProvidedServiceInstances are referencing the same ApplicationEndpoint via localUnicastAddress then the source IP address, the source port number, and the Level 4 protocol (Udp) fields of header of IP packets containing event PDUs that are sent to the clients of the ProvidedServiceInstances are identical. In such a scenario, the ProvidedServiceInstances may use identical method Ids (i.e. identical Header Ids) if at least one of the following conditions holds for any pair of the ProvidedServiceInstances:

a) At any point in time only one of the ProvidedServiceInstances is active

b) If two or more ProvidedServiceInstances can send Events at the same time, the ProvidedServiceInstances may still use identical method Ids if at least one of the following IP header fields of the IP packet containing the event is different for any pair of Event PDUs identified by the same Method Id:

b1) Destination IP address (== IP address of client)

b2) Destination port number (== client port number)

In all other cases, the method ids of the two PSIs should not overlap.

In other words if several ProvidedServiceInstances with the same serviceIdentifier and different majorVersions are located on the same Socket for transmission of particular Events, then the different ProvidedServiceInstances need to use a different client Addresses (different Port or IP Address) or the Events of all those ProvidedServiceInstances need to have unique MethodIds.

6.7.5.15 Summary of supported configuration options between ApplicationEndpoints

The following table summarizes the configuration options that are supported by the System Template and were described in the chapters above.

[TPS_SYST_02396] Summary of supported configuration options between ApplicationEndpoints ⌈

Communication Scenario	Configuration on Provider Side	Configuration on Consumer Side	Usage of SD module
dynamic Service Discovery configuration: Service Consumer finds Service Provider at runtime	ProvidedServiceInstance with defined localUnicastAddress and without remoteUnicastAddress	ConsumedServiceInstance with defined localUnicastAddress and without remoteUnicastAddress	SD module is used and is configured.
dynamic event subscription with known peers: Service Consumer knows Service Provider from configuration. But Service Consumer needs to subscribe to EventGroups to receive events from Service Provider	ProvidedServiceInstance with defined localUnicastAddress and with defined remoteUnicastAddress	ConsumedServiceInstance with defined localUnicastAddress and with defined remoteUnicastAddress.	SD module is used and is configured. Service Offer and Service Find do not need to be performed. The SocketConnections in the SoAd can be setup without ServiceDiscovery since the Service Provider and Service Consumer know each other from the configuration. The subscription to EventGroups is still performed via ServiceDiscovery
Static configuration: Addresses (IP Address, Port) of Data Provider and Data Consumer are predefined in the configuration. Exchanged data is predefined and assigned to the StaticSocketConnection that is defined between Service Consumer and ServiceProvider	Definition of StaticSocketConnection on the SocketAddress belonging to the ServiceProvider. StaticSocketConnection defines the target of the communication with the remoteAddress. A ProvidedServiceInstance is not defined.	Definition of StaticSocketConnection. A ConsumedServiceInstance is not defined.	SD module is not used

⌋

6.7.5.16 Firewall

AUTOSAR Classic supports the integration of a firewall as a host firewall or as a firewall inside an Ethernet switch.

[TPS_SYST_03096] Firewall on a Host ECU

Upstream requirements: RS_SYST_00065

⌈If an EcuInstance refers to at least one StateDependentFirewall in the role firewallRule, then a firewall is configured for that EcuInstance.⌋

[TPS_SYST_03097] Firewall on an Ethernet Switch

Upstream requirements: RS_SYST_00065

⌈If a CouplingElement where the couplingType is set to the value CouplingElementEnum.switch refers to at least one StateDependentFirewall in the role firewallRule, then a firewall is configured for that Ethernet switch.⌋

The AUTOSAR Firewall module offers a mechanism to dynamically enable/disable Firewall rules at runtime. The Firewall module is connected to the BswM, which switches the Firewall State to allow for dynamic firewall behavior based on the current vehicle state (e.g. driving, parking, in a diagnostic session). The System Template models this aspect with the StateDependentFirewall.firewallStateModeDeclaration reference to a ModeDeclaration of a ModeDeclarationGroup. Please note that in this case the modeling of the Firewall State Machine is not done via a ModeDeclarationGroupPrototype but directly via a ModeDeclarationGroup that is an ARElement.

[constr_9317] StateDependentFirewall.firewallStateModeDeclaration reference restriction

Imposition time: IT_SysDesc

⌈Each StateDependentFirewall shall only reference ModeDeclarations in the role firewallStateModeDeclaration that are aggregated by the same ModeDeclarationGroup.⌋

In other words all used Firewall States that are modeled as ModeDeclarations shall be collected in the same ModeDeclarationGroup.

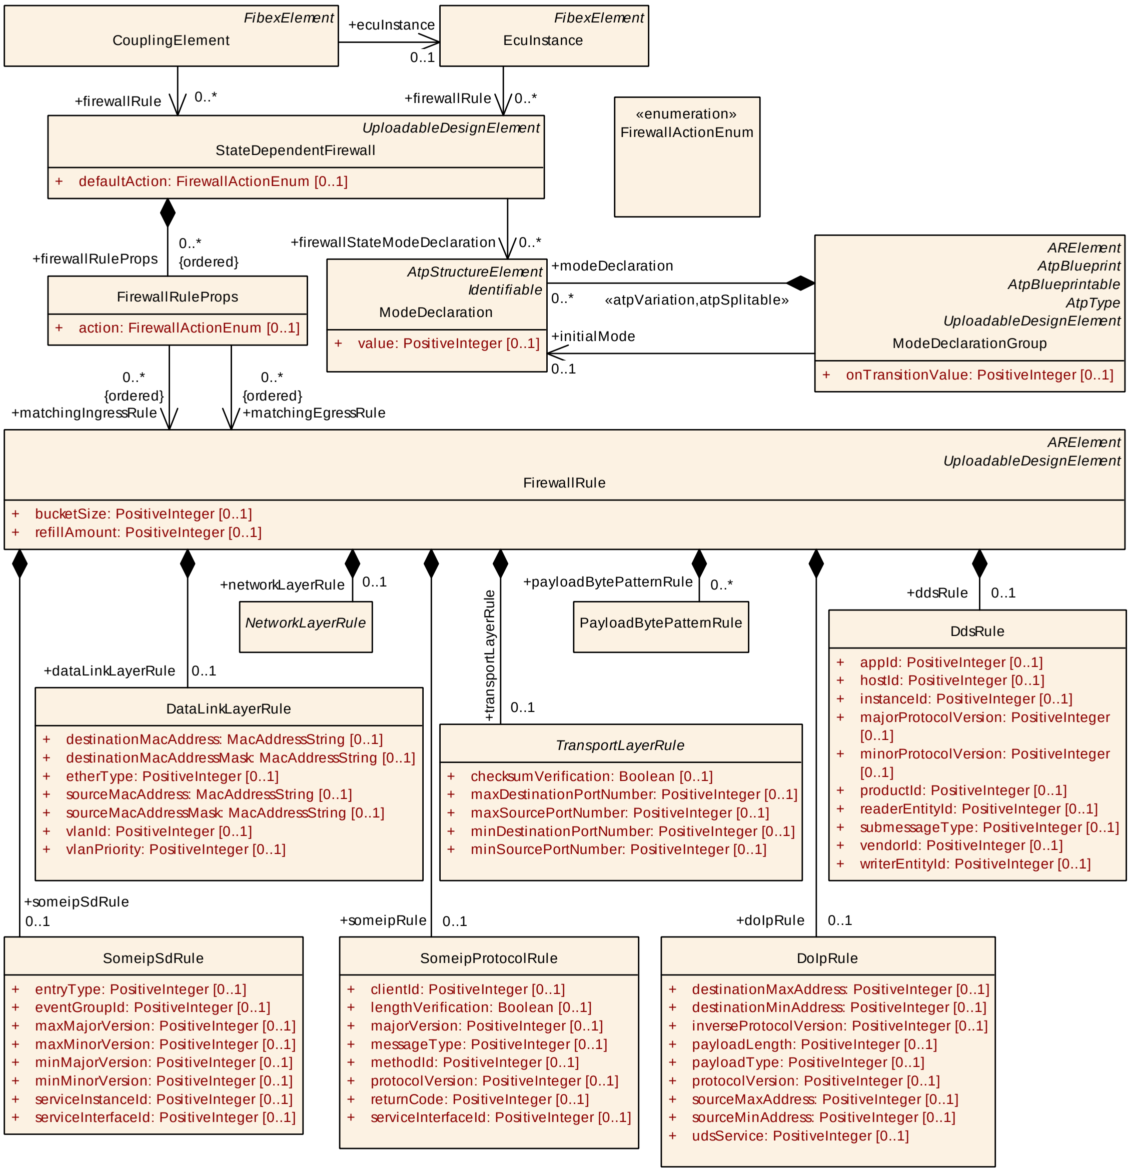

Figure 6.68: Firewall configuration

The details on the configuration of the `StateDependentFirewall` and `FirewallRule`s can be found in the Manifest specification for the Adaptive platform [32].

6.7.5.17 ACL check

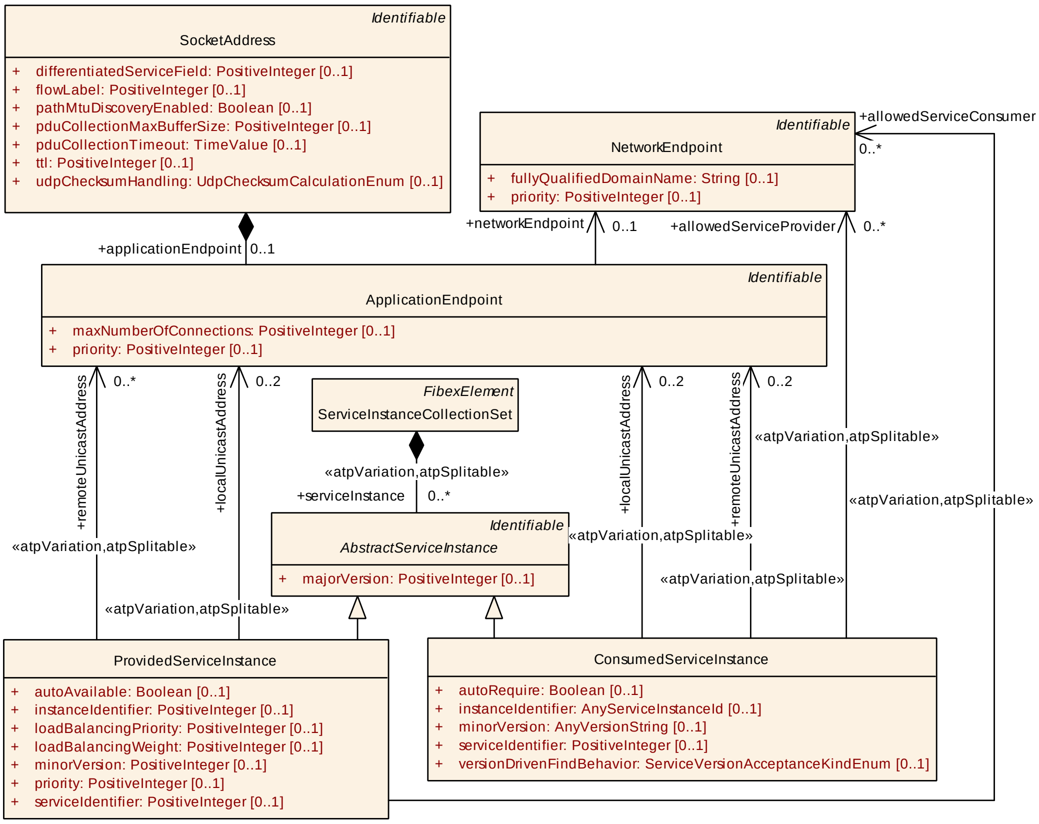

Figure 6.69: ACL check configuration

The ACL check in the AUTOSAR Service Discovery module allows to limit the Ethernet communication, so that a service instance can only be accessed by predefined and known communication partners.

[TPS_SYST_02401] ACL check definition for a `ProvidedServiceInstance` ⌈The `ProvidedServiceInstance`.`allowedServiceConsumer` reference allows to define a list of `NetworkEndpoint`s on which `ConsumedServiceInstance`s can be located that are allowed to access the `ProvidedServiceInstance`.⌋

[TPS_SYST_02402] ACL check definition for a `ConsumedServiceInstance` ⌈The `ConsumedServiceInstance`.`allowedServiceProvider` reference allows to define a `NetworkEndpoint` on which `ProvidedServiceInstance` can be located that is allowed to provide data to the `ConsumedServiceInstance`.⌋

6.8 Transport Layer

In AUTOSAR, the Transport Layer has two main purposes: The segmentation and re-assembly of messages that are too long to fit into one frame on the underlying communication cluster, and the re-use of fixed frame identifiers for different message content.

According to the AUTOSAR Layered Software Architecture [33], each type of communication cluster has its own definition of the Transport Layer. Consequently, the peculiarities of the cluster types are addressed in the System Template by having different detailed models for FlexRay, CAN, LIN and J1939. However, all models are embedded into the communication model: They use specialized classes of TpConfig as a root element into the TP configuration.

[TPS_SYST_01099] Context of TpConfig

Upstream requirements: RS_SYST_00014

⌈A TpConfig element is existing always in the context of exactly one CommunicationCluster.⌋

All Transport Layers will take IPdus as input elements, which will be transferred in the form of one or more NPdus. A TpConnection (FlexrayTpConnection, CanTpConnection, LinTpConnection, J1939TpConnection) identifies a connection link between different communication nodes and routes the Pdus between them.

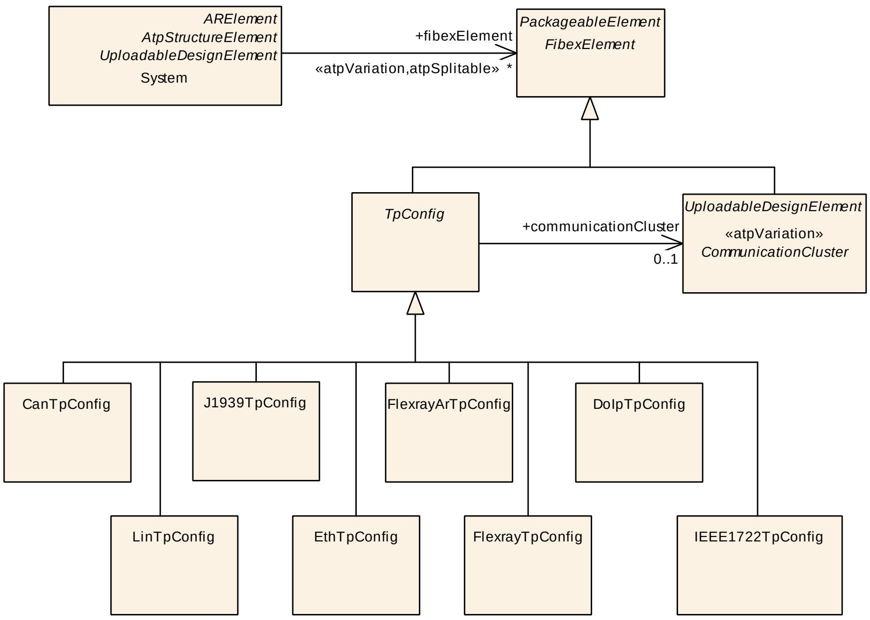

Figure 6.70: Transport Layer Overview

Examples in chapter 6.8.9 and chapter 6.8.10 illustrate the usage of the TP model.

Class	***TpConfig*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	Contains all configuration elements for AUTOSAR TP.			
Base	*ARObject*, *CollectableElement*, *FibexElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Subclasses	CanTpConfig, DoIpTpConfig, EthTpConfig, FlexrayArTpConfig, FlexrayTpConfig, IEEE1722TpConfig, J1939TpConfig, LinTpConfig, SomeipTpConfig			
Aggregated by	ARPackage.element			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
communication Cluster	CommunicationCluster	0..1	ref	A TpConfig is existing always in the context of exactly one CommunicationCluster.

Table 6.238: TpConfig

Class	**TpAddress**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	An ECUs TP address on the referenced channel. This represents the diagnostic Address.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	FlexrayArTpConfig.tpAddress, FlexrayTpConfig.tpAddress, J1939TpConfig.tpAddress, LinTpConfig.tp Address			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
tpAddress	Integer	0..1	attr	An ECUs TP address on the referenced channel. This represents the diagnostic Address.

Table 6.239: TpAddress

[constr_9226] Existence of `TpConfig.communicationCluster`

Imposition time: `IT_SysDesc`

⌈For each `TpConfig`, the reference to `CommunicationCluster` in the role `communicationCluster` shall exist.⌋

[constr_9227] Existence of `TpAddress.tpAddress`

Imposition time: `IT_SysDesc`

⌈For each `TpAddress`, the attribute `tpAddress` shall exist.⌋

[constr_3025] Usage of `NPdu`s in `TpConnections`

Imposition time: `IT_SysDesc`

⌈In case several `TpConnection`s use the same Frame ID for their communication needs only one `NPdu` element per Frame Id shall exist. This constraint applies for all supported AUTOSAR transport protocols (CanTp, LinTp, FrTp, FrArTp and J1939Tp).⌋

Note: Depending on the capabilities of the Basic Software implementations of Tp and Interface the ECU Configuration of the respective BSW Modules may utilize more communication elements (`NPdu`s).

Example for an allowed System Template description where the same FrameId is used by two different TpConnections:

```
TpConnection1 --(dataPdu)--> NPdu1 ----> FrameId1
TpConnection1 --(flowControl)--> NPdu2 ----> FrameId2
TpConnection2 --(dataPdu)--> NPdu2 ----> FrameId2
TpConnection2 --(flowControl)--> NPdu1 ----> FrameId1
```

The following Ecu configuration with additional NPdus can still be derived from the above system description:

```
TpConnection1 --(dataPdu)--> NPdu1 ----> FrameId1
TpConnection1 --(flowControl)--> NPdu2 ----> FrameId2
TpConnection2 --(dataPdu)--> NPdu3 ----> FrameId2
TpConnection2 --(flowControl)--> NPdu4 ----> FrameId1
```

[constr_3090] TpSdu transmission on a PhysicalChannel

Imposition time: IT_SysDesc

⌈The IPdu that is referenced by a TpConnection in the role tpSdu shall be referenced by exactly one PduTriggering aggregated on the PhysicalChannel of the TpConnection.⌋

The corresponding PduTriggering for the IPdu referenced from the TpConnection in the role tpSdu is aggregated by the PhysicalChannel which points to the same CommunicationConnector which is referenced by TpNode that this TpConnection points to.

Please note that with [constr_3090] the multiple transmission of the same TpSdu over a specific channel using TP is only possible if several IPdus and TpConnections are created.

6.8.1 Transport Layer Routing

The transformations in the TP modules take a significant amount of time and resources and therefore two different Transport Layer routing approaches are supported by AUTOSAR.

[TPS_SYST_01100] TP routing without using transport protocol modules (low-level routing)

Upstream requirements: RS_SYST_00014

⌈The behavior can be optimized if source and target use the same transport protocol (e.g. CanTp-to-CanTp routing). In this case the inbound NPDU can be directly forwarded to the PduR and then sent on the outbound bus without any (resource consuming) TP module involvement.⌋

[TPS_SYST_01101] TP routing using transport protocol modules

Upstream requirements: RS_SYST_00014

⌈In case that transport protocol modules are involved in the routing operation the incoming NPDUs need to be:

- forwarded to corresponding inbound TP module and reassembled into an SDU (represented as IPdu)
- the SDU needs to be forwarded to the PduR
- the PduR routes the SDU to the outgoing TP module
- the outbound TP module segments the SDU into NPDUs which are then sent on the target bus.

⌋

6.8.2 FlexRay ISO Transport Layer

The FlexRay ISO 10681-2 Transport Layer supports multiple sessions, i.e. multiple segmented transfers can be handled at the same time. Thus, multiple FlexrayTpConnections can be defined on the same ECU. Each FlexrayTpConnection is controlled by configuration parameters defined in FlexrayTpConnectionControl.

[TPS_SYST_01102] FlexrayTpConnectionControl reuse

Upstream requirements: RS_SYST_00014

⌈The same FlexrayTpConnectionControl may be reused for an arbitrary number of FlexrayTpConnections.⌋

A FlexrayTpConnection defines the way of communication between a sender and a receiver and uses a FlexrayTpPduPool of NPdus to transmit data to the FlexRay Interface.

[TPS_SYST_01103] FlexrayTpConnection shall specify one txPduPool

Upstream requirements: RS_SYST_00014

⌈Each FlexrayTpConnection shall specify one txPduPool with at least one nPdu.⌋

In order to achieve a higher bandwidth a txPduPool may contain more than one transmit NPdu, e.g. if all referenced NPdus are transmitted in different FlexrayFrames in the same cycle.

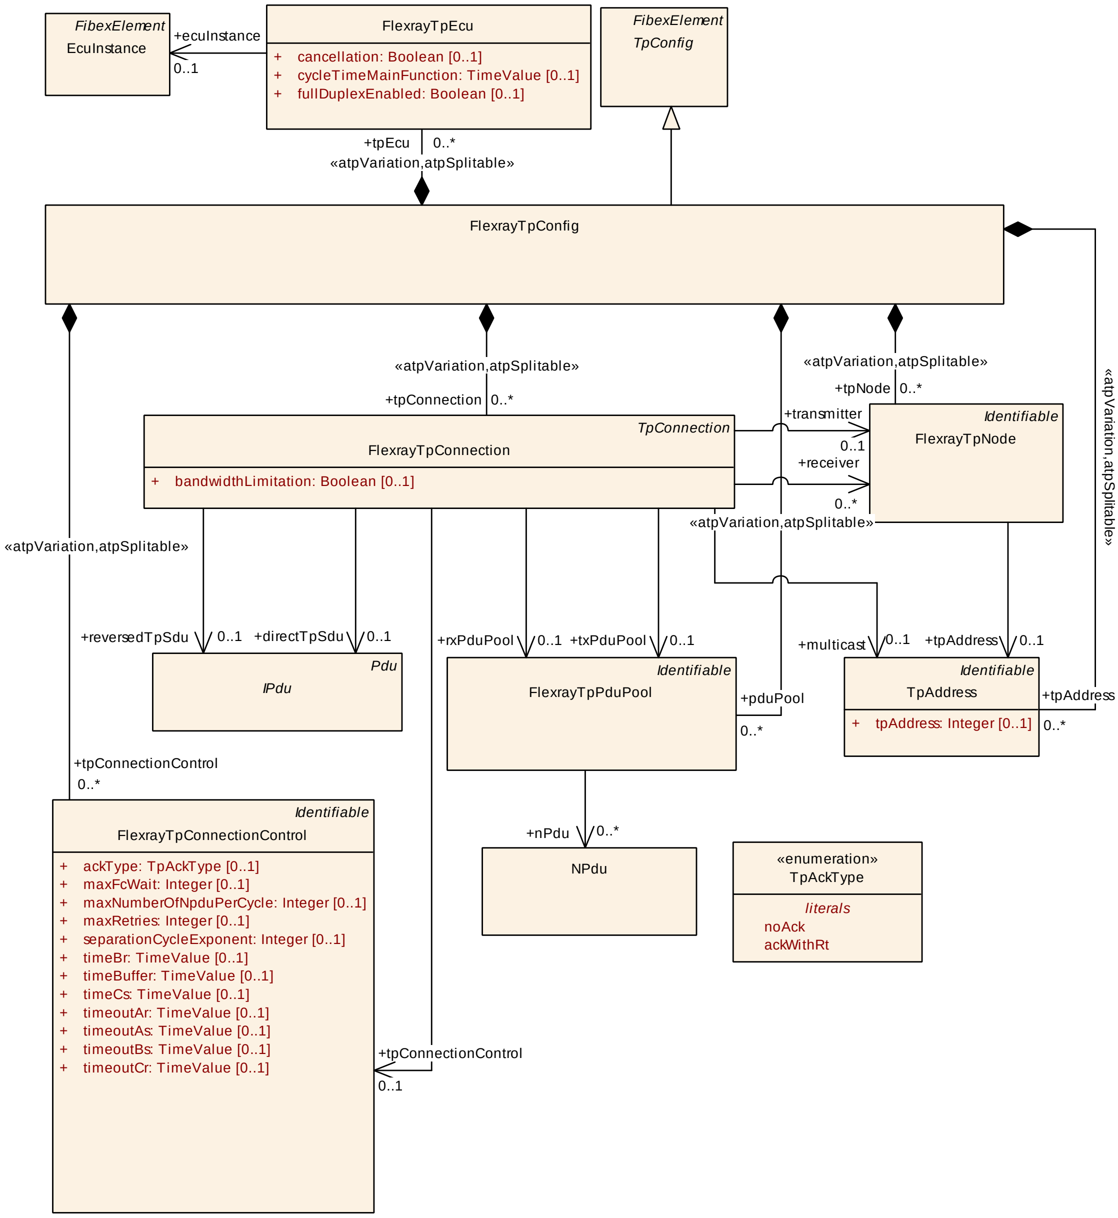

Figure 6.71: FlexRay ISO Transport Layer Configuration (TransportProtocols: FlexRay-IsoTransportProtocol)

FlexrayTpConnections are specifically used for communication between one source and one or several target devices. These communication partners are specified using the transmitter and receiver associations to FlexrayTpNodes, providing the diagnostic tpAddress and the connection to the topology.

[TPS_SYST_01104] FlexrayTpConnection with several receivers

Upstream requirements: RS_SYST_00014

⌈In case of several receivers a multicast tpAddress shall be used.⌋

The actual payload to be transported by the FlexrayTpConnection is specified by using either one or two references to IPdus, depending on whether the connection shall be used unidirectional (one reference) or bidirectional (two references).

Class	**FlexrayTpConfig**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	This element defines exactly one FlexRay ISO TP Configuration. One FlexRayTpConfig element shall be created for each FlexRay Network in the System that uses Flex Ray Iso Tp. **Tags:** atp.recommendedPackage=TpConfigs

Class	**FlexrayTpConnectionControl**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	Configuration parameters to control a FlexRay TP connection.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	FlexrayTpConfig.tpConnectionControl			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
ackType	TpAckType	0..1	attr	This parameter defines the type of acknowledgement which is used for the specific channel.
maxFcWait	Integer	0..1	attr	This attribute defines the maximum number of Flow Control N-PDUs with FlowState "WAIT".
maxNumberOfNpduPerCycle	Integer	0..1	attr	This parameter limits the number of N-Pdus the sender is allowed to transmit within a FlexRay cycle.
maxRetries	Integer	0..1	attr	This parameter defines the maximum number of retries (if retry is configured for the particular channel).
separationCycleExponent	Integer	0..1	attr	Exponent to calculate the minimum number of "Separation Cycles" the sender has to wait for the next transmission of an FrTp N-Pdu.
timeBr	TimeValue	0..1	attr	Time (in seconds) until transmission of the next Flow Control N-PDU.
timeBuffer	TimeValue	0..1	attr	This parameter defines the time of waiting for the next try to get a Tx or Rx buffer. This parameter is equivalent to the temporal distance between two FC.WT N-Pdus in case the buffer request returns busy. Specified in seconds.
timeCs	TimeValue	0..1	attr	Time (in seconds) until transmission of the next ConsecutiveFrame NPdu / LastFrame NPdu.
timeoutAr	TimeValue	0..1	attr	This parameter states the timeout between the PDU transmit request of the Transport Layer to the FlexRay Interface and the corresponding confirmation of the Flex Ray Interface on the receiver side (for FC or AF). Specified in seconds.

▽

△

Class	**FlexrayTpConnectionControl**			
timeoutAs	TimeValue	0..1	attr	This attribute states the timeout between the PDU transmit request for the first PDU of the group used in the current connection of the Transport Layer to the FlexRay Interface and the corresponding confirmation of the Flex Ray Interface (when having sent the last PDU of the group used in this connection) on the sender side (SF-x, FF-x, CF or FC (in case of Transmit Cancellation)). Specified in seconds.
timeoutBs	TimeValue	0..1	attr	This parameter defines the timeout in seconds for waiting for an FC or AF on the sender side in a 1:1 connection.
timeoutCr	TimeValue	0..1	attr	This parameter defines the timeout value in seconds for waiting for a CF or FF-x (in case of retry) after receiving the last CF or after sending an FC or AF on the receiver side. Specified in seconds.

Table 6.241: FlexrayTpConnectionControl

Class	**FlexrayTpConnection**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	A connection identifies the sender and the receiver of this particular communication. The FlexRayTp module routes a Pdu through this connection. In a System Description the references to the PduPools are mandatory. In an ECU Extract these references can be optional: On unicast connections these references are always mandatory. On multicast the txPduPool is mandatory on the sender side. The rxPduPool is mandatory on the receiver side. On Gateway ECUs both references are mandatory.			
Base	*ARObject*, *TpConnection*			
Aggregated by	FlexrayTpConfig.tpConnection			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
bandwidth Limitation	Boolean	0..1	attr	Specifies whether the connection requires a bandwidth limitation or not.
directTpSdu	IPdu	0..1	ref	Reference to the IPdu that is segmented by the Transport Protocol.
multicast	TpAddress	0..1	ref	TP address for 1:n connections.
receiver	FlexrayTpNode	*	ref	The target of the TP connection.
reversedTpSdu	IPdu	0..1	ref	Reference to the IPdu that is segmented by the Transport Protocol. If support of both sending and receiving is used, this association references the IPdu used for the additional second direction.
rxPduPool	FlexrayTpPduPool	0..1	ref	A connection has a reference to a set of NPdus (FrTpRx PduPool) which are defined for receiving data via this particular connection. The following constraint is valid only for the System Extract/ECU Extract: In case this connection is applied to the transmitter the rxPduPool holds the actually received NPdus. In case this connection is applied to the receiver the rxPduPool holds the actually sent NPdus.
tpConnection Control	FlexrayTpConnection Control	0..1	ref	Reference to the connection control.
transmitter	FlexrayTpNode	0..1	ref	The source of the TP connection.

▽

△

Class	FlexrayTpConnection			
txPduPool	FlexrayTpPduPool	0..1	ref	A connection has a reference to a set of NPdus (FrTpTx PduPool) which are defined for sending data via this particular connection. The following constraint is valid only for the System Extract/ECU Extract: In case this connection is applied to the transmitter the txPduPool holds the actually sent NPdus. In case this connection is applied to the receiver the txPduPool holds the actually received NPdus.

Table 6.242: FlexrayTpConnection

[constr_9231] Existence of FlexrayTpConnection.directTpSdu

Imposition time: IT_SysDesc

⌈For each FlexrayTpConnection, the reference to IPdu in the role directTpSdu shall exist.⌋

[constr_9233] Existence of FlexrayTpConnection.receiver

Imposition time: IT_SysDesc

⌈For each FlexrayTpConnection, the reference to FlexrayTpNode in the role receiver shall exist at least once.⌋

[constr_9234] Existence of FlexrayTpConnection.tpConnectionControl

Imposition time: IT_SysDesc

⌈For each FlexrayTpConnection, the reference to FlexrayTpConnectionControl in the role tpConnectionControl shall exist.⌋

[constr_9235] Existence of FlexrayTpConnection.transmitter

Imposition time: IT_SysDesc

⌈For each FlexrayTpConnection, the reference to FlexrayTpNode in the role transmitter shall exist.⌋

The FlexrayTpConnection refers to the FlexrayTpPduPool in two roles: rxPduPool and txPduPool.

[TPS_SYST_01064] Transmit/Receive Semantics of Pdu Pools ⌈The transmit/receive semantics of Pdu Pools depends on the role of the regarded ECU:

- If the ECU is the transmitter then the txPduPool holds the sent NPdus and the rxPduPool holds the received NPdus.
- If the ECU is the receiver then the txPduPool holds the received NPdus and the rxPduPool holds the sent NPdus.

⌋

The following example shows how this differentiation may be used:

System Description:
SENDER = A
RECEIVER = B
TxPool = PDU_1
RxPool = PDU_2

ECU Extract of A:
SENDER = A
TxPool = PDU_1 -> sent Pdus
RxPool = PDU_2 -> received Pdus

Since on receiver side the PDU_1 is received and PDU_2 is sent (from a local point of view) the export shall look like this:
ECU Extract of B:
RECEIVER = B
TxPool = PDU_1 -> received Pdus
RxPool = PDU_2 -> sent Pdus

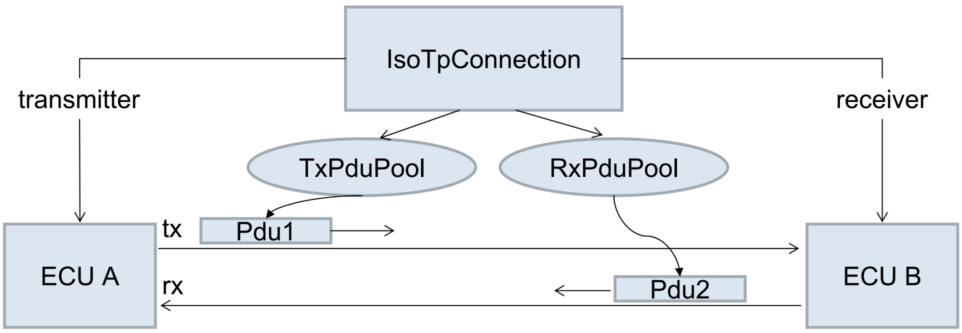

Figure 6.72: IsoTp Example

Imposition time: IT_SysDesc

⌈For each FlexrayTpEcu, the reference to EcuInstance in the role ecuInstance shall exist.⌋

[constr_9237] Existence of FlexrayTpEcu.fullDuplexEnabled

Imposition time: IT_SysDesc

⌈For each FlexrayTpEcu, the attribute fullDuplexEnabled shall exist.⌋

[constr_5374] IPdu shall only be referenced once from a FlexrayTpConnection in the role directTpSdu or reversedTpSdu on a FlexrayCluster

Imposition time: IT_SysDesc

⌈Each IPdu that is referenced in the role directTpSdu or reversedTpSdu from a FlexrayTpConnection that is aggregated by a FlexrayTpConfig that references a FlexrayCluster shall not be referenced a second time in the role directTpSdu or reversedTpSdu from any FlexrayTpConnection that is aggregated by a FlexrayTpConfig that references the same FlexrayCluster.⌋

6.8.3 FlexRay AUTOSAR Transport Layer

This section describes a Non-ISO FlexRay TP protocol that is supported by AUTOSAR in addition to the FlexRay ISO 10681-2 TP (see section 6.8.2). The Non-ISO FlexRay Transport Layer supports multiple sessions, i.e. multiple segmented transfers can be handled at the same time.

A FlexrayArTpChannel provides a Tx and an Rx pool of NPdus which are used by the associated FlexrayArTpConnections.

FlexrayArTpConnections are used for communication between one source and one or more target device(s). These communication partners are specified by the source and target associations to FlexrayArTpNodes, providing the diagnostic TpAddresses and the connection to the topology description. The actual payload to be transported by the FlexrayArTpConnection is identified by the references directTpSdu and reversedTpSdu to IPdus. When one of the two SDUs is omitted, the connection shall be used unidirectional.

[constr_5315] FlexrayArTpConnections within the same FlexrayArTpChannel not allowed to have the same address information

Imposition time: IT_SysDesc

⌈FlexrayArTpConnections that are aggregated by the same or reverse FlexrayArTpChannel are not allowed to reference the same pair of FlexrayArTpNodes.⌋

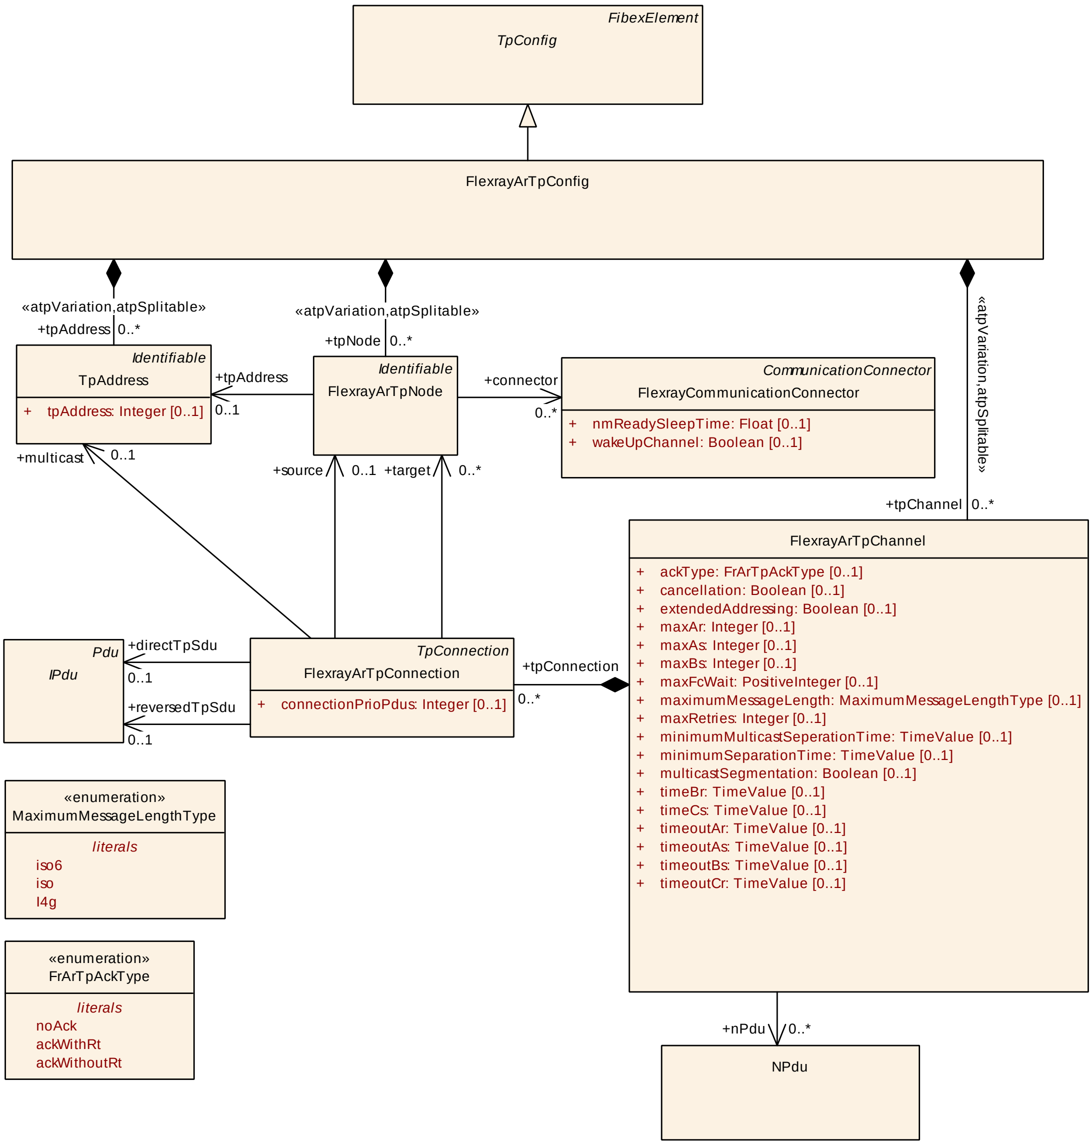

Figure 6.73: FlexRay Autosar Transport Layer Configuration (TransportProtocols: FlexRayAutosarTransportProtocol)

minimum Multicast SeperationTime	TimeValue	0..1	attr	This attribute defines the minimum amount of time between two succeeding CFs of a 1:n segmented transmission in seconds. Valid values are 0, 100µs, 200µs ... 900µs, 1ms, 2ms .. 127ms. The value can be changed at runtime using the FrArTp_ChangeParameter interface. minimumMulticastSeparationTime shall be an integer multiple of the cycle length multiplied with the multiplexing factor, i.e. minimumMulticastSeparationTime = n * cycle * m, where n is an integer >= 0, cycle is Flexray Cluster.cycle, and m is the cycle multiplexor of those cycles where PDUs of the PDU pool are scheduled. Please note: Due to the scheduling strategies of FrTp, minimumMulticastSeparationTime can only be kept to a degree defined by the maximum temporal distance of the PDUs of a PDU pool within one FlexRay cycle. Range: 0 .. 0.127
minimum SeparationTime	TimeValue	0..1	attr	This attribute defines the minimum amount of time between two succeeding CFs of a 1:1 segmented transmission in seconds. Valid values are 0, 100µs, 200µs .. 900µs, 1ms, 2ms .. 127ms. The value can be changed at runtime using the FrArTp_ChangeParameter interface. The minimumSeparationTime shall be an integer multiple of the cycle length multiplied with the multiplexing factor, i.e. minimumSeparationTime = n * cycle * m, where n is an integer >=0, cycle is FlexrayCluster.cycle, and m is the cycle multiplexor of those cycles where PDUs of the PDU pool are scheduled. Please note: Due to the scheduling strategies of FrTp, minimumSeparationTime can only be kept to a degree defined by the maximum temporal distance of the PDUs of a PDU pool within one FlexRay cycle. Range: 0 .. 0.127
multicast Segmentation	Boolean	0..1	attr	This attribute defines whether segmentation within a 1:n connection is allowed or not.
nPdu	NPdu	*	ref	A FlexRayTpChannel references a set of NPdus. These NPdus are logically assembled into a pool of Rx NPdus and another pool of Tx NPdus. It shall be ensured that a second channel either references all NPdus of such a pool, or none.
timeBr	TimeValue	0..1	attr	This attribute defines the time in seconds between receiving the last CF of a block or an FF-x (or SF-x) and sending out an FC or AF.
timeCs	TimeValue	0..1	attr	This attribute defines the time in seconds between the sending of two consecutive frames or between a consecutive frame and a flow control (for Transmit Cancellation) or between reception of an flow control or Acknowledgement Frame and sending of the next consecutive frame or a flow control (for Transmit Cancellation).
timeoutAr	TimeValue	0..1	attr	This attribute states the timeout in seconds between the PDU transmit request of the Transport Layer to the Flex Ray Interface and the corresponding confirmation of the FlexRay Interface on the receiver side (for FC or AF).

▽

△

Class	FlexrayArTpChannel			
timeoutAs	TimeValue	0..1	attr	This attribute states the timeout in seconds between the PDU transmit request for the first PDU of the group used in the current connection of the Transport Layer to the FlexRay Interface and the corresponding confirmation of the FlexRay Interface (when having sent the last PDU of the group used in this connection) on the sender side (SF-x, FF-x, CF).
timeoutBs	TimeValue	0..1	attr	This attribute defines the timeout in seconds for waiting for an FC or AF on the sender side in a 1:1 connection.
timeoutCr	TimeValue	0..1	attr	This attribute defines the timeout value in seconds for waiting for a CF or FF-x (in case of retry) after receiving the last CF or after sending an FC or AF on the receiver side.
tpConnection	FlexrayArTpConnection	*	aggr	Group of connections that can be used in this channel.

Enumeration	**MaximumMessageLengthType**
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols
Note	Type of Acknowledgement.
Aggregated by	FlexrayArTpChannel.maximumMessageLength
Literal	***Description***
I4g	SF-E allowed (SF of arbitrary length depending on FrTpPduLength), up to (2**32)-1 byte message length (all FF-x allowed). **Tags:** atp.EnumerationLiteralIndex=0
iso	Up to (2**12)-1 Byte message length (No FF-Ex or SF-E or AF shall be used and recognized). **Tags:** atp.EnumerationLiteralIndex=1
iso6	As ISO, but the maximum payload length is limited to 6 byte (SF-I, FF-I, CF). This is necessary to route TP on CAN when using Extended Addressing or Mixed Addressing on CAN. **Tags:** atp.EnumerationLiteralIndex=2

Table 6.251: MaximumMessageLengthType

[constr_5375] IPdu shall only be referenced once from a FlexrayArTpConnection in the role directTpSdu or reversedTpSdu on a FlexrayCluster

Imposition time: IT_SysDesc

⌈Each IPdu that is referenced in the role directTpSdu or reversedTpSdu from a FlexrayArTpConnection that is aggregated by a FlexrayArTpConfig that references a FlexrayCluster shall not be referenced a second time in the role directTpSdu or reversedTpSdu from any FlexrayArTpConnection that is aggregated by a FlexrayArTpConfig that references the same FlexrayCluster.⌋

6.8.4 CAN Transport Layer

The CAN Transport Layer supports multiple sessions by means of CanTpChannels: Each CanTpChannel uses its own resources, such as internal buffer, timer, state machine and thus can operate independently and simultaneously to other CanTpChannels. The same session can be reused for an arbitrary number of CanTpConnections.

Each CanTpConnection uses its own pair of NPdus: One NPdu, the dataPdu is mandatory for each CanTpConnection, the flowControlPdu is optional depending whether only Single Frames are transferred over the connection.

A CanTpConnection is specifically used for communication between source and target devices. These communication partners are specified using the transmitter and receiver associations to CanTpNode, providing the diagnostic tpAddress and the connection to the topology.

[TPS_SYST_01146] Generic CanTpConnections ⌈If the transmitter or the receiver of a CanTpConnection is not specified then the CanTpConnection is a generic one (address information is not determined).⌋

[TPS_SYST_01105] CanTpConnection with several receivers

Upstream requirements: RS_SYST_00014

⌈In case of several receivers a multicast tpAddress shall be used.⌋

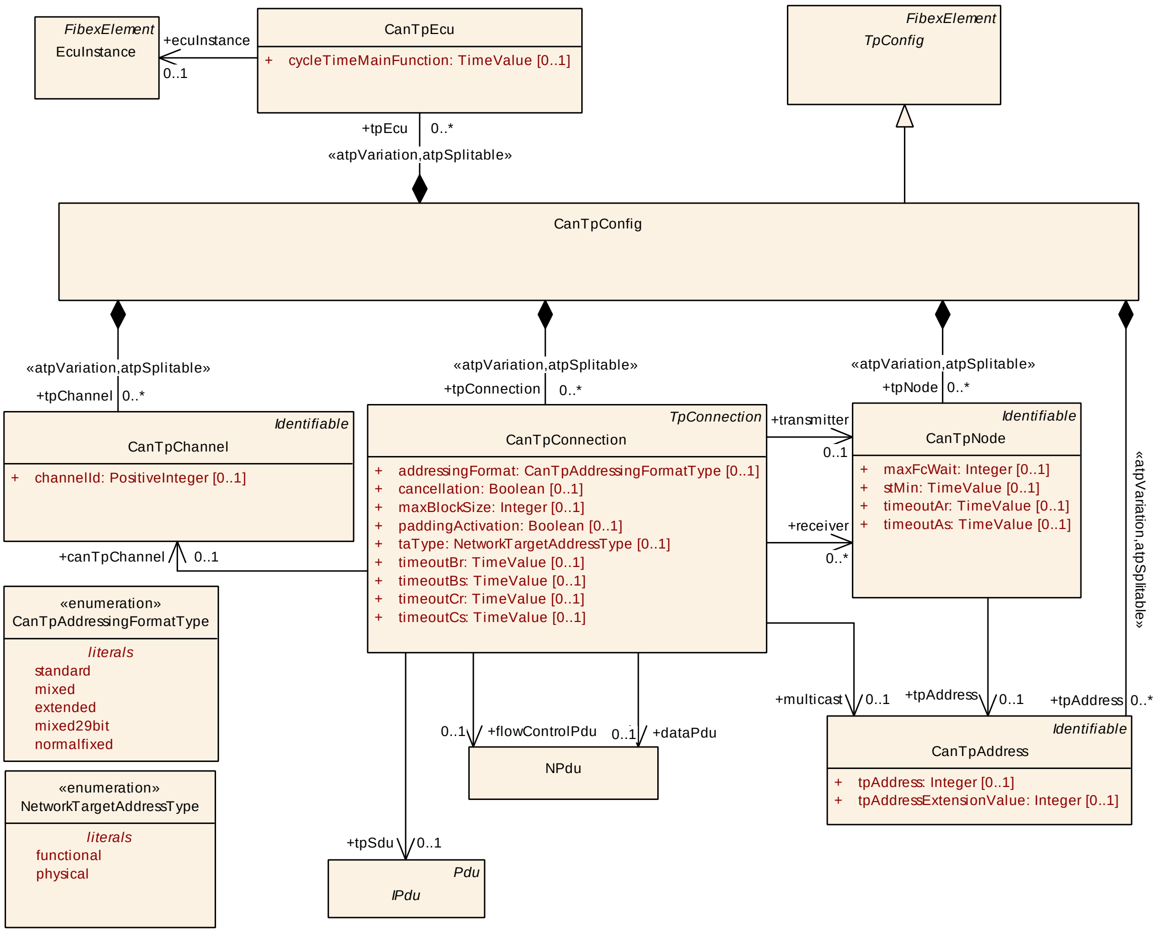

Figure 6.74: CAN Transport Layer Configuration (TransportProtocols: CanTransportProtocol)

The actual payload to be transported by the `CanTpConnection` is specified by the reference `tpSdu` to `IPdu`.

The `N_TAtype` communication models as defined in ISO 15765-2 [34] can be expressed using a combination of the attributes `addressingFormat` (`CanTpAddressingFormatType`) and `taType` (`NetworkTargetAddressType`).

Aggregated by	CanTpConfig.tpConnection			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
addressingFormat	CanTpAddressingFormatType	0..1	attr	Declares which communication addressing mode is supported.
cancellation	Boolean	0..1	attr	With this switch Tx Cancellation can be turned on or off. Please note that the Rx Cancellation is always enabled.
canTpChannel	CanTpChannel	0..1	ref	Reference to the CanTpChannel on which this CanTp Connection is realized.
dataPdu	NPdu	0..1	ref	Reference to an Data NPdu.
flowControlPdu	NPdu	0..1	ref	Reference to the Flow Control NPdu.

▽

△

Class	CanTpConnection			
maxBlockSize	Integer	0..1	attr	The maximum number of N-PDUs the CanTp receiver allows the sender to send, before waiting for an authorization to continue transmission of the following N-PDUs. For further details on this parameter value see ISO 15765-2 specification. Note: For reasons of buffer length, the CAN Transport Layer can adapt the BS value within the limit of this maximum BS
multicast	CanTpAddress	0..1	ref	TP address for 1:n connections.
padding Activation	Boolean	0..1	attr	This specifies whether or not Sfs, FCs and the last CF shall be padded to 8 bytes length in case it contains less payload. true: The N-PDU received uses padding for SF, FC and the last CF. (N-PDU length is always 8 bytes) false: The N-PDU received does not use padding for SF, CF and the last CF. (N-PDU length is dynamic)
receiver	CanTpNode	*	ref	The target of the TP connection.
taType	NetworkTargetAddress Type	0..1	attr	Network Target Address type.
timeoutBr	TimeValue	0..1	attr	Value in seconds of the performance requirement for (N_Br + N_Ar). N_Br is the elapsed time between the receiving indication of a FF or CF or the transmit confirmation of a FC, until the transmit request of the next FC.
timeoutBs	TimeValue	0..1	attr	This parameter defines the timeout for waiting for an FC or AF on the sender side in an 1:1 connection. Specified in seconds.
timeoutCr	TimeValue	0..1	attr	This parameter defines the timeout value for waiting for a CF or FF-x (in case of retry) after receiving the last CF or after sending an FC or AF on the receiver side. Specified in seconds.
timeoutCs	TimeValue	0..1	attr	The attribute timeoutCs represents the time (in seconds) which elapses between the transmit request of a CF N-PDU until the transmit request of the next CF N-PDU.
tpSdu	IPdu	0..1	ref	Reference to an IPdu that is segmented by the Transport Protocol.
transmitter	CanTpNode	0..1	ref	The source of the TP connection.

6.8.5 LIN Transport Layer

LinTpConnection is used for modeling communication resources required for using the LIN Transport Layer. Contrary to the FlexRay and CAN Transport Layers, LIN TP only supports one session per PhysicalChannel.

An arbitrary number of LinTpConnections per LinTpConfig can be defined since the transmission of data from master to slave, using the MasterRequest frame, and the transmission of data from slave to master, using the SlaveResponse frame, needs to be described per NAD the LinMaster uses to address one or more of its LinSlaves.

LinTpConnection uses the dataPdu reference for specifying exactly one NPdu which is to be used for transmitting the data, and it optionally references a flowControl NPdu in order to handle Flow Control Frames if required.

One LinTpConnection is specifically used for communication between one source and one or several target devices. These communication partners are specified using the transmitter and receiver associations to LinTpNode, providing the diagnostic tpAddress and the connection to the topology. In case of several receivers a multicast tpAddress shall be used.

The actual payload to be transported by the LinTpConnection is specified by the reference linTpNSdu to IPdu.

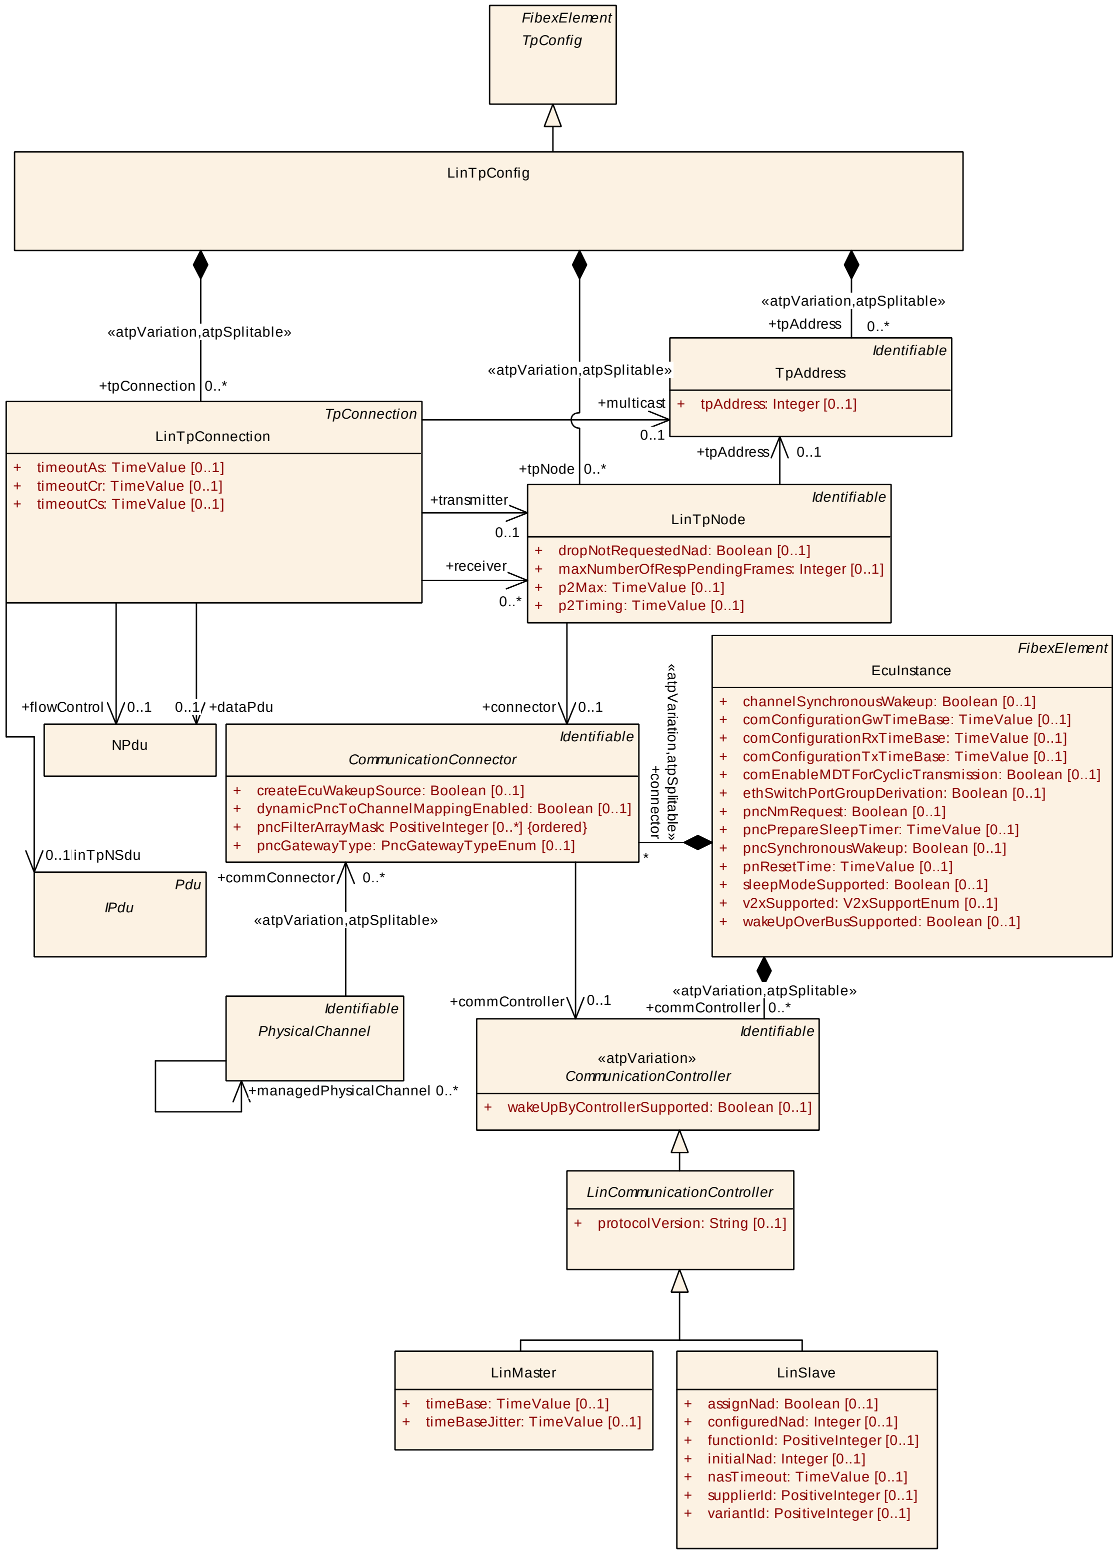

Figure 6.75: LIN Transport Layer Configuration

Class	LinTpConfig

△

Class	**LinTpNode**			
connector	Communication Connector	0..1	ref	Association to a CommunicationConnector in the topology description. In a System Description this reference is mandatory. In an ECU Extract this reference is optional (references to ECUs that are not part of the ECU Extract shall be avoided).
dropNot RequestedNad	Boolean	0..1	attr	Configures if TP Frames of not requested LIN-Slaves are dropped or not.
maxNumberOf RespPending Frames	Integer	0..1	attr	Configures the maximum number of allowed response pending frames.
p2Max	TimeValue	0..1	attr	After reception of a response pending frame the P2 timeout counter is reloaded with the timeout time P2max.
p2Timing	TimeValue	0..1	attr	P2 timeout observation parameter.
tpAddress	TpAddress	0..1	ref	Reference to the TP Address that is used by the TpNode. This reference is optional in case that the multicast TP Address is used (reference from TpConnection).

Table 6.261: LinTpNode

Class	**LinTpConnection**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	A LinTP channel represents an internal path for the transmission or reception of a Pdu via LinTp and describes the sender and the receiver of this particular communication. LinTp supports (per Lin Cluster) the configuration of one Rx Tp-SDU and one Tx Tp-SDU per NAD the LinMaster uses to address one or more of its Lin Slaves. To support this an arbitrary number of LinTp Connections shall be described.			
Base	*ARObject*, *TpConnection*			
Aggregated by	LinTpConfig.tpConnection			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
dataPdu	NPdu	0..1	ref	Reference to an NPdu (Single Frame, First Frame or Consecutive Frame). The Single Frame network protocol data unit (SF N_PDU) shall be sent out by the sending network entity and can be received by one or multiple receiving network entities. The Single Frame (SF N_PDU) shall be sent out to transfer a service data unit that can be transferred via a single service request to the data link layer. This network protocol data unit shall be sent to transfer unsegmented messages. The First Frame network protocol data unit (FF N_PDU) identifies the first network protocol data unit (N_PDU) of a segmented message transmitted by a network sending entity and received by a receiving network entity. The Consecutive Frame network protocol data unit (CF N_PDU) transfers segments (N_Data) of the service data unit message data (<MessageData>). All network protocol data units (N_PDUs) transmitted by the sending entity after the First Frame network protocol data unit (FF N_PDU) shall be encoded as Consecutive Frames network protocol data units (CF N_PDUs).

▽

△

Class	LinTpConnection			
flowControl	NPdu	0..1	ref	Reference to the Flow Control NPdu. The Flow Control network protocol data unit (FC N_PDU) is identified by the Flow Control protocol control information (FC N_PCI). The Flow Control network protocol data unit (FC N_PDU) instructs a sending network entity to start, stop or resume transmission of CF N_PDUs. The Flow Control network protocol data unit shall be sent by the receiving network layer entity to the sending network layer entity, when ready to receive more data, after correct reception of: a) First Frame network protocol data unit (FF N_PDU) b) the last Consecutive Frame network protocol data unit (CF N_PDU) of a block of Consecutive Frames (CF N_PDU) if further Consecutive Frame network protocol data unit (CF N_PDU) need(s) to be sent.
linTpNSdu	IPdu	0..1	ref	Reference to the IPdu that is segmented by the Transport Protocol.
multicast	TpAddress	0..1	ref	TP address for 1:n connections.
receiver	LinTpNode	*	ref	The target of the TP connection.
timeoutAs	TimeValue	0..1	attr	Time for transmission of the LIN frame (any N-PDU) on the sender side. Specified in seconds.
timeoutCr	TimeValue	0..1	attr	This attribute defines the timeout value for waiting for a CF or FF-x (in case of retry) after receiving the last CF or after sending an FC or AF on the receiver side. Specified in seconds.
timeoutCs	TimeValue	0..1	attr	The attribute timeoutCs represents the time (in seconds) which elapses between the transmit request of a CF N-PDU until the transmit request of the next CF N-PDU.
transmitter	LinTpNode	0..1	ref	The source of the TP connection.

⌈For each LinTpConnection, the reference to NPdu in the role dataPdu shall exist.⌋

[constr_9261] Existence of LinTpConnection.linTpNSdu

Imposition time: IT_SysDesc

⌈For each LinTpConnection, the reference to IPdu in the role linTpNSdu shall exist.⌋

[constr_9262] Existence of LinTpConnection.receiver

Imposition time: IT_SysDesc

⌈For each LinTpConnection, at least one reference to LinTpNode in the role receiver shall exist.⌋

[constr_9263] Existence of LinTpConnection.transmitter

Imposition time: IT_SysDesc

⌈For each LinTpConnection, the reference to LinTpNode in the role transmitter shall exist.⌋

[constr_5377] IPdu shall only be referenced once from a LinTpConnection in the role linTpNSdu on a LinCluster

Imposition time: IT_SysDesc

⌈Each IPdu that is referenced in the role linTpNSdu from a LinTpConnection that is aggregated by a LinTpConfig that references a LinCluster shall not be referenced in the role linTpNSdu from a different LinTpConnection that is aggregated by a LinTpConfig that references the same LinCluster.⌋

6.8.6 Ethernet Transport Layer

The Transport Layer in the AUTOSAR Ethernet protocol stack is defined by the TcpIp module. For the transmission of an upper layer module Pdu via an UDP or TCP socket, the AUTOSAR Socket Adaptor specifies a Pdu route which is linked to a socket connection. The upper layer module of the SoAd may use the Interface (IF) API or the Transport Protocol (TP) API for the transmit request and data provision respectively.

With the EthTpConnection it is possible to describe in a System Description that the TP API shall be used for a specific Pdu route. If a PduTriggering is not referenced by a EthTpConnection the IF API will be used.

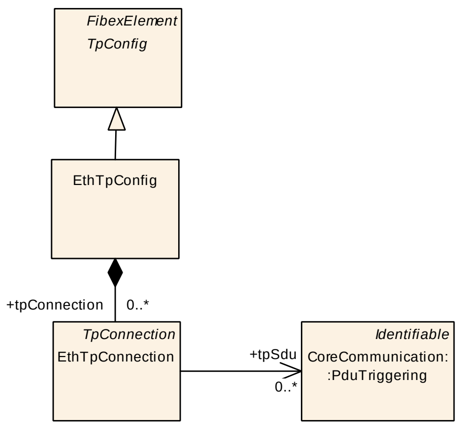

Figure 6.76: Modeling of EthTpConnection

Aggregated by	EthTpConfig.tpConnection			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
tpSdu	PduTriggering	*	ref	Reference to a PduTriggering that shall be transported using the "TP" semantics.

Table 6.264: EthTpConnection

6.8.7 SOME/IP segmenter

On the transmission side SOME/IP TP segments an incoming SOME/IP IPdu that does not fit into a single UDP Package into smaller GeneralPurposeIPdus with category SOMEIP_SEGMENTED_IPDU and allows to transport SOME/IP messages over UDP that are greater than 128KB. On the reception side the large IPdu is reassembled again. The Message Type field of the SOME/IP header contains a bit, which marks the SOME/IP message as a segment of an original SOME/IP message. Every segmented SOME/IP message adds SOME/IP TP specific fields to the SOME/IP header. These fields contain control information for the segmentation and the reassembly of original, large SOME/IP messages.

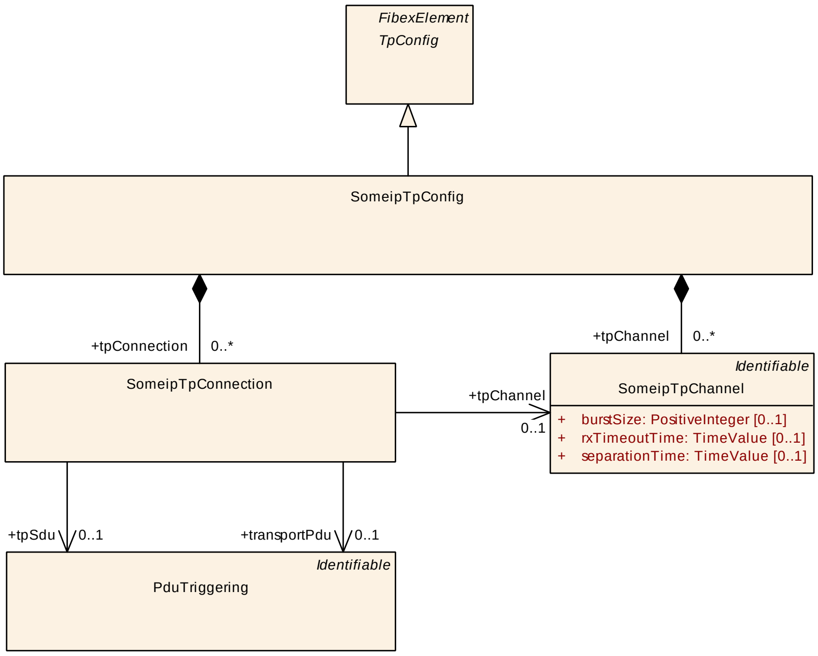

Figure 6.77: SOME/IP Segmenter

Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SomeipTpConfig.tpChannel			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
burstSize	PositiveInteger	0..1	attr	Specifies the number of segments that shall be transmitted in a burst ignoring separationTime. SeparationTime will then only be applied between bursts. If not configured, SeparationTime will be applied between all frames.
rxTimeoutTime	TimeValue	0..1	attr	Timer to monitor the successful reception. It is started when the first NPdu is received, restarted after reception of intermediate NPdus, and is stopped when the last NPdu has been received.
separationTime	TimeValue	0..1	attr	Sets the duration of the minimum time in seconds the SOME/IP TP module shall wait between the transmissions of NPdus.

Table 6.267: SomeipTpChannel

[constr_3328] `SomeipTpConnection.transportPdu` reference restriction

Imposition time: `IT_SysDesc`

⌈A `PduTriggering` that is referenced by a `SomeipTpConnection` in the role `transportPdu` shall reference a `GeneralPurposeIPdu` with category SOMEIP_SEGMENTED_IPDU in the role `iPdu`.⌋

[constr_3329] `SomeipTpConnection.tpSdu` reference restriction

Imposition time: `IT_SysDesc`

⌈A `PduTriggering` that is referenced by a `SomeipTpConnection` in the role `tpSdu` shall reference an `IPdu` in the role `iPdu`.⌋

[TPS_SYST_02156] Length of GeneralPurposeIPdu with category SOMEIP_SEGMENTED_IPDU

Upstream requirements: RS_SYST_00050, RS_SYST_00039, RS_SYST_00014

⌈The length of GeneralPurposeIPdu with category SOMEIP_SEGMENTED_IPDU that is referenced by a PduTriggering in the role iPdu that in turn is referenced by a SomeipTpConnection in the role transportPdu defines the maximum size in bytes of a segment.⌋

Please note that the length of a GeneralPurposeIPdu with category SOMEIP_SEGMENTED_IPDU covers 8 bytes of the SOME/IP header, 4 bytes of the TP header, and the segment itself.

[constr_3330] Same transportPdu shall not be used in different SomeipTpConnections

Imposition time: IT_SysDesc

⌈A PduTriggering that is referencing a GeneralPurposeIPdu with category SOMEIP_SEGMENTED_IPDU in the role iPdu shall be referenced at most once by a SomeipTpConnection in the role transportPdu.⌋

[constr_5378] PduTriggering shall only be referenced once from a SomeipTpConnection in the role tpSdu

Imposition time: IT_SysDesc

⌈Each PduTriggering that is referenced in the role tpSdu from a SomeipTpConnection shall not be referenced in the role tpSdu from a different SomeipTpConnection.⌋

6.8.8 SAE J1939 Transport Layer

There are two transport protocol variants defined by J1939: BAM (Broadcast Announce Message), which is a broadcast protocol that does not use any flow control, and CMDT (Connection Mode Data Transfer), which is a point-to-point protocol with flow control and acknowledgment.

BAM uses two NPdus for transport, TP.CM (Transport Protocol Command, flowControlPdu) and TP.DT (Transport Protocol Data, dataPdu). CMDT uses three NPdus, because an additional TP.CM (flowControlPdu) in reverse direction is needed for flow control. The length of TP.CM and TP.DT NPdus is fixed to 8 bytes.

[TPS_SYST_01106] Usage of additional directPdu in case of variable length sdu

Upstream requirements: RS_SYST_00014, RS_SYST_00038

⌈In case of variable length sdu (with system signals of variable length) an additional directPdu is required:

- it is used if the current length of this sdu is up to 8 bytes.
- if the current length of this sdu is higher than 8 bytes the sdu will be transported via the dataPdu.

⌋

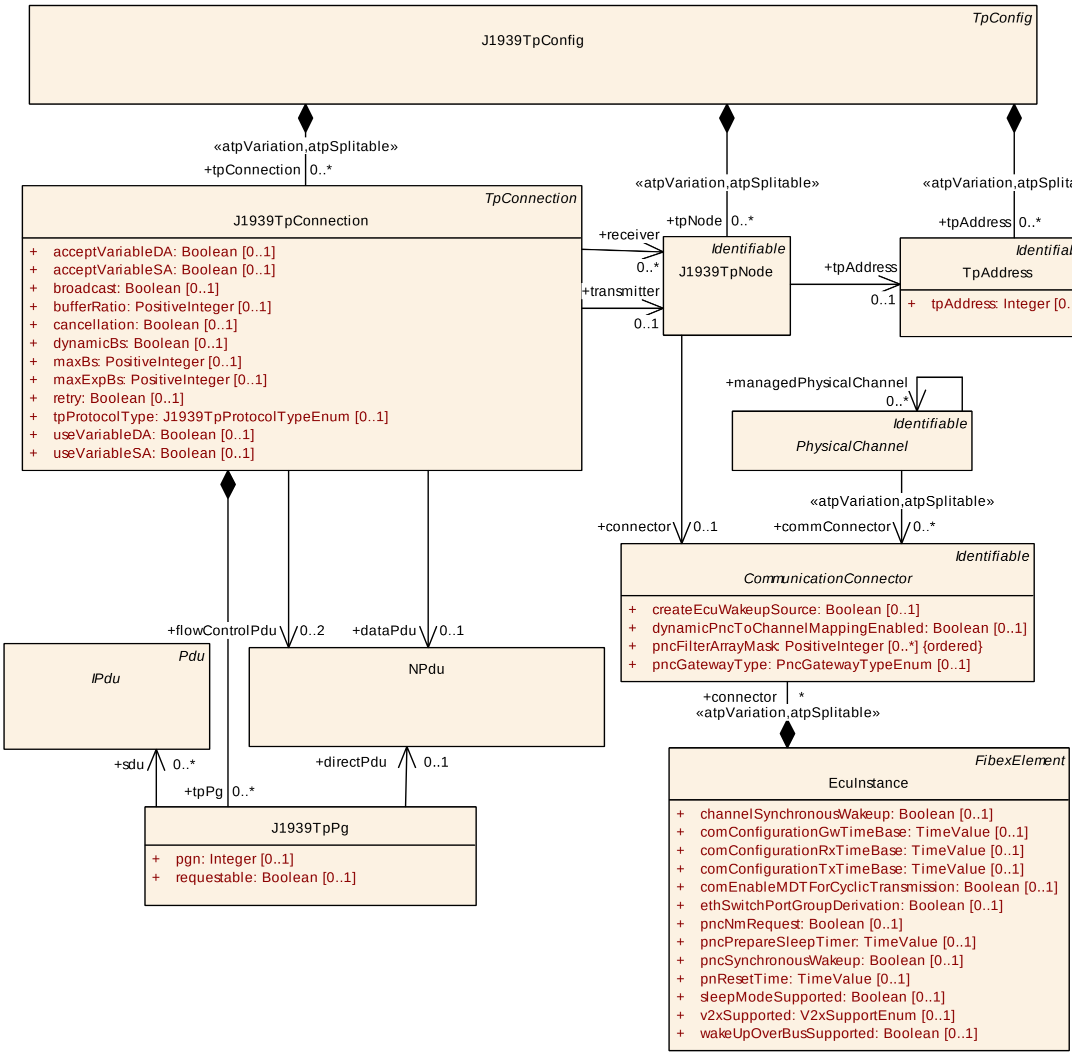

Figure 6.78: J1939 Transport Layer Configuration

A J1939TpConnection is specifically used for communication between source and target devices. These communication partners are specified using the transmitter and receiver associations to J1939TpNode, providing the diagnostic tpAddress and the connection to the topology.

[TPS_SYST_02190] J1939TpConnection.transmitter reference in case of broadcast connection

Upstream requirements: RS_SYST_00014, RS_SYST_00038

⌈In case of a broadcast connection the J1939TpConnection shall only reference the J1939TpNode in the role transmitter. The reason is that BAM (Broadcast Announce Message) is always directed at the target address 0xff and therefore no receiver reference is necessary.⌋

[TPS_SYST_02191] J1939TpConnection.transmitter reference in case that the source is an unknown node

Upstream requirements: RS_SYST_00014, RS_SYST_00038

⌈In case that the source is an unknown node, e.g. an arbitrary tester, the J1939TpConnection is allowed to omit the transmitter reference to J1939TpNode.⌋

[TPS_SYST_02192] J1939TpConnection.receiver reference in case that the destination is an unknown node

Upstream requirements: RS_SYST_00014, RS_SYST_00038

⌈In case that the destination is an unknown node, e.g. an arbitrary tester, the J1939TpConnection is allowed to omit the receiver reference to J1939TpNode.⌋

[TPS_SYST_02193] J1939TpConnection.receiver reference in case that the destination is connected to a configured J1939NmNode

Upstream requirements: RS_SYST_00014, RS_SYST_00038

⌈In case that the destination is connected to a configured J1939NmNode, the J1939TpConnection shall reference the J1939TpNode in the role receiver. It means that the receiving J1939TpNode is associated with an EcuInstance via the CommunicationConnector and this EcuInstance is associated with a J1939NmNode via the NmEcu. In this case the nmNodeId of the J1939NmNode corresponds to the TpAddress defined by J1939TpNode.⌋

The Parameter Group (PG) to be transported by the J1939TpConnection is specified by the tpPg aggregation.

[TPS_SYST_01147] Generic J1939TpConnections ⌈If the transmitter or the receiver of a J1939TpConnection is not specified then the J1939TpConnection is a generic one (address information is not determined).⌋

Class	**J1939TpConnection**			
Package	M2::AUTOSARTemplates::SystemTemplate::TransportProtocols			
Note	A J1939TpConnection represents an internal path for the transmission or reception of a Pdu via J1939Tp and describes the sender and the receiver of this particular communication. The J1939Tp module routes a Pdu (J1939 PGN) through the connection.			
Base	*ARObject*, *TpConnection*			
Aggregated by	J1939TpConfig.tpConnection			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
acceptVariableDA	Boolean	0..1	attr	The TP message is accepted independently of the actually used destination address (DA). Otherwise, only the destination address configured as receiver.tpAddress is accepted. Only derived for the receiving ECU.
acceptVariableSA	Boolean	0..1	attr	The TP message is accepted independently of the actually used source address (SA). Otherwise, only the source address configured as transmitter.tpAddress is accepted. Only derived for the receiving ECU.

▽

△

Class	**J1939TpConnection**			
broadcast	Boolean	0..1	attr	BAM (Broadcast Announce Message) is a broadcast protocol. If this attribute is set to true broadcast is used. Since address FF is the only broadcast address, there's no reason to configure it. **Tags:** atp.Status=obsolete
bufferRatio	PositiveInteger	0..1	attr	Defines usage of available data for dynamic block size calculation when protocol retry is enabled. This attribute describes in percent of available buffer that shall be used for retry.
cancellation	Boolean	0..1	attr	Enable support for Tx/Rx cancellation.
dataPdu	NPdu	0..1	ref	Data Message (TP.DT) used by CMDT and BAM. The DataNPdu has a fixed length of 8 bytes.
dynamicBs	Boolean	0..1	attr	Enable support for dynamic block size calculation.
flowControlPdu	NPdu	0..2	ref	Reference to the Command NPdus (TP.CM) that are used in the CMDT (Connection Mode Data Transfer) in both directions. BAM uses one TP.CM (Transport Protocol Command). The flowControlNPdu has a fixed length of 8 bytes. Please note that the role name "flowControlIPdu" is misleading and is kept for backward compatibilty reasons.
maxBs	PositiveInteger	0..1	attr	Set maximum block size (number of packets in TP.CM_CTS).
maxExpBs	PositiveInteger	0..1	attr	Set maximum for expected block size (maximum number of packets in TP.CM_RTS).
receiver	J1939TpNode	*	ref	The target of the TP connection.
retry	Boolean	0..1	attr	Enable support for protocol retry.
tpPg	J1939TpPg	*	aggr	J1939 messages (parameter groups, PGs) that can be transferred via this connection.
tpProtocolType	J1939TpProtocolTypeEnum	0..1	attr	Protocol type used by the J1939TpConnection
transmitter	J1939TpNode	0..1	ref	The source of the TP connection.
useVariableDA	Boolean	0..1	attr	The TP message is sent with variable destination address (DA). Otherwise, the destination address configured as receiver.tpAddress is always used. Only derived for the transmitting ECU.
useVariableSA	Boolean	0..1	attr	The TP message is sent with variable source address (SA). Otherwise, the source address configured as transmitter.tpAddress is always used. Only derived for the transmitting ECU.

Imposition time: IT_SysDesc

⌈Each IPdu that is referenced in the role sdu from a J1939TpPg that is aggregated by a J1939TpConfig that references a J1939Cluster shall not be referenced in the role sdu from a different J1939TpPg that is aggregated by a J1939TpConfig that references the same J1939Cluster.⌋

6.8.9 Unicast TP Example

The example in Figure 6.79 illustrate the usage of the System Template TP model. In this System Description example the Sender ECU (Tester) communicates with the Receiver ECU (Diagnostic Server) via two Gateways (GW1 and GW2).

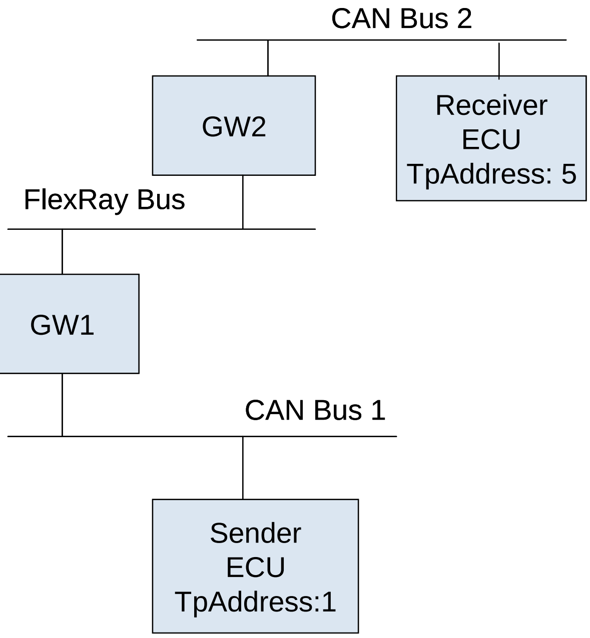

Figure 6.79: TP unicast Example

CAN Bus 1 (CanTpConfig 1):
  CanTpConnection (CanTpConnection1)
    transmitter TpNode: Sender ECU, TpAddress: 1
    receiver TpNode: GW1, TpAddress: 5
  CanTpConnection (CanTpConnection2):
    transmitter TpNode: GW1, TpAddress: 5
    receiver TpNode: Sender ECU, TpAddress: 1

FlexRay Bus (FlexRayTpConfig):
  FlexRayTpConnection (FlexrayTpConnection1):
    transmitter TpNode: GW1, TpAddress: 1
    receiver TpNode: GW2, TpAddress: 5

CAN Bus 2 (CanTpConfig 2):
  CanTpConnection (CanTpConnection3):
    transmitter TpNode: GW2, TpAddress: 1
    receiver TpNode: Receiver ECU, TpAddress: 5
  CanTpConnection (CanTpConnection4):
    transmitter TpNode: Receiver ECU, TpAddress: 5
    receiver TpNode: GW2, TpAddress: 1

DiagnosticConnection:
  physicalRequest TpConnection: CanTpConnection3
  response TpConnection: CanTpConnection4

Please note that two different CanTpConfig elements are created for the two CAN networks. The TpAddress of the transmitter TpNode is always 1 and the TpAddress of the receiver TpNode is always 5, even in the FlexrayTpConfig where Gateway ECU1 communicates with Gateway ECU2. The original transmitter and the final receiver are addressed in each connection. Please note that for CanTp for each direction an own CanTpConnection is used.

The DiagnosticConnection is modeled only for the last segment to which the Receiver ECU that represents the diagnostic server is connected.

6.8.10 Multicast TP Example

A second example illustrates the usage of the multicast reference.

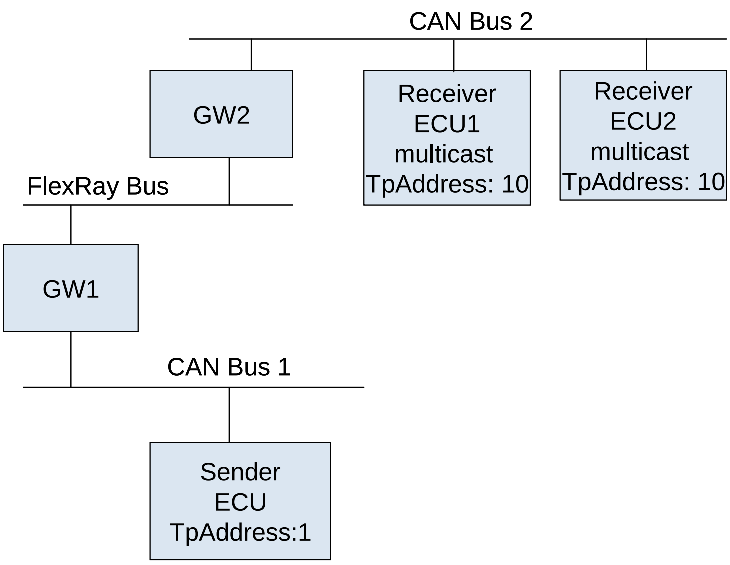

Figure 6.80: TP multicast Example

```
Can Bus 1 (CanTpConfig1):
CanTpConnection
  source TpNode: Sender ECU, TpAddress: 1
  target TpNode: GW1
  multicast TpAddress: 10

FlexRay Bus  (FlexRayTpConfig):
FlexRayTpConnection
  source TpNode: GW1, TpAddress: 1
  target TpNode: GW2
  multicast TpAddress: 10

CAN Bus 2 (CanTpConfig 2):
CanTpConnectionChannel
  source TpNode: GW2, TpAddress: 1
  target TpNode: Receiver ECU1
  target TpNode: Receiver ECU2
```

```
multicast TpAddress: 10
```

Please note that the target TpNode does not contain a reference to the TpAddress. The multicast TpAddress is described by a direct reference from the connection.

6.8.11 Diagnostic Connection

A prominent use of the TP in automotive systems is the implementation of diagnostic communication. Data send from and to the tester frequently exceeds the native size of a communication package on typical bus systems used for this purpose.

However, the mere usage of TP channels for diagnostic purposes is missing one important aspect: TP channels, as defined by the AUTOSAR standard, are unidirectional by nature.

For diagnostic communication, it is very important to be able to define pairs of TP connections that can be taken to send related *request* and *response* messages.

In order to support this use case the meta-class `DiagnosticConnection` has been introduced.

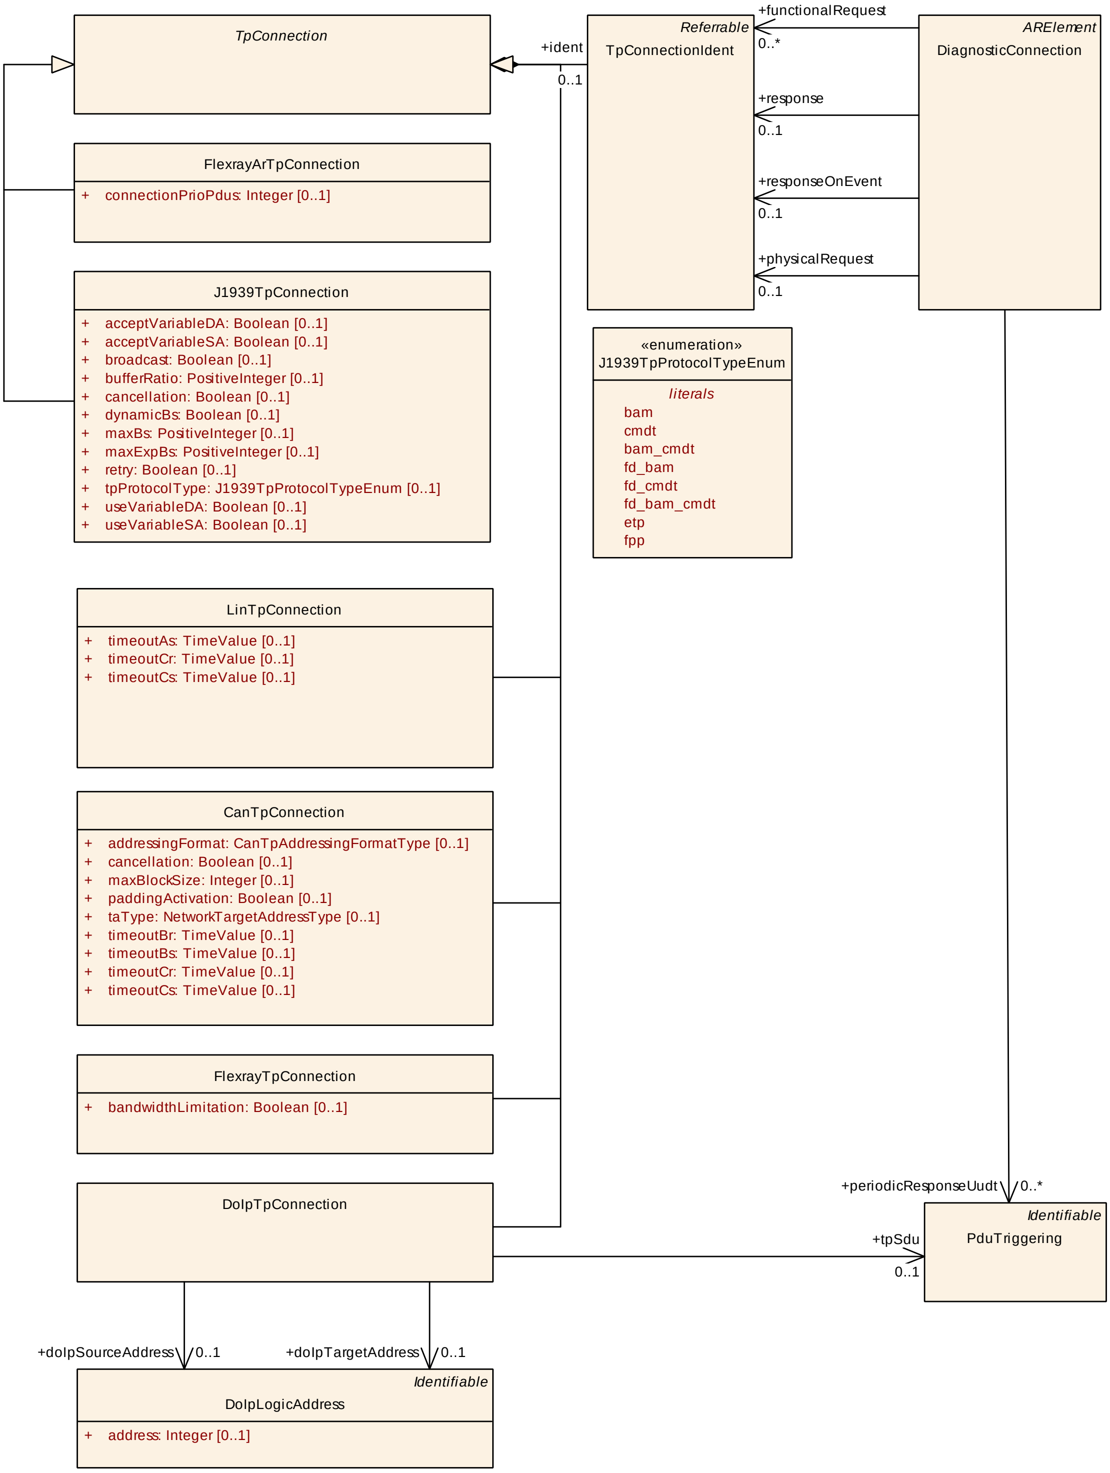

Figure 6.81: Modeling of DiagnosticConnection

[TPS_SYST_05003] Usage of DiagnosticConnection in combination with a TP
⌈DiagnosticConnection allows for the dedicated identification of TP connections used for the various diagnostic message sending use cases:

- functionalRequest

- physicalRequest
- responseOnEvent
- response

⌋

[TPS_SYST_05004] Usage of DiagnosticConnection in combination with UUDT ⌈In addition to the usage of TP connections, the DiagnosticConnection foresees the transmission of UUDT message for **periodic response**. For this purpose, the role periodicResponseUudt is supported.⌋

[constr_1367] periodicResponseUudt.periodicResponseUudt shall only refer to a DcmIPdu

Imposition time: IT_SysDesc

⌈If the role periodicResponseUudt exists then every PduTriggering referenced in the role periodicResponseUudt shall only refer to a DcmIPdu.⌋

Please note that the meta-class TpConnectionIdent (derived from Referrable) has been introduced for the purpose of allowing sub-classes of TpConnection to become the target of a reference while preserving full backwards-compatibility to the previous modeling.

This means in particular that the existence of a shortName is only required if the sub-class of TpConnection shall actually represent the target of a reference in the context of the definition of a DiagnosticConnection.

This, however, is kind of self-evident (because the reference would not work without the existence of a shortName at the reference target) and therefore it is not necessary to formulate an explicit constraint that clarifies this issue.

[constr_1368] Limitation of the target of references from DiagnosticConnection

Imposition time: IT_SysDesc

⌈DiagnosticConnection shall only reference (via the indirection created by TpConnectionIdent) the following sub-classes of the meta-class TpConnection:

- CanTpConnection
- FlexrayTpConnection
- FlexrayArTpConnection
- DoIpTpConnection

⌋

6.8.12 IEEE1722 Transport Layer

`IEEE1722Tp` is a transport protocol for Time-Sensitive Applications [35].

On the Ethernet IEEE1722Tp is represented by an own AVTP Ethertype [35]. From an AUTOSAR layered architecture perspective the IEEE1722Tp messages are handled by the IEEE1722Tp module.

In AUTOSAR the Audio Video Transport Protocol (AVTP) supports two major use-cases:

- clock reference, audio, and video transport
- control message transport (e.g. CAN frame transport).

The elaborate modelling of the IEEE1722Tp subtype messages (e.g. for audio, video, or control data) provides details about the kind of messages transported. Thus producer and consumer have a common understanding of the payload.

This elaborate modelling of the IEEE1722Tp subtype messages allows also for a detailed definition of the actually required bandwidth on the ethernet channel. This supports the calculation of the busload.

The common parts to define an IEEE1722Tp message are described using the IEEE1722TpConnection.

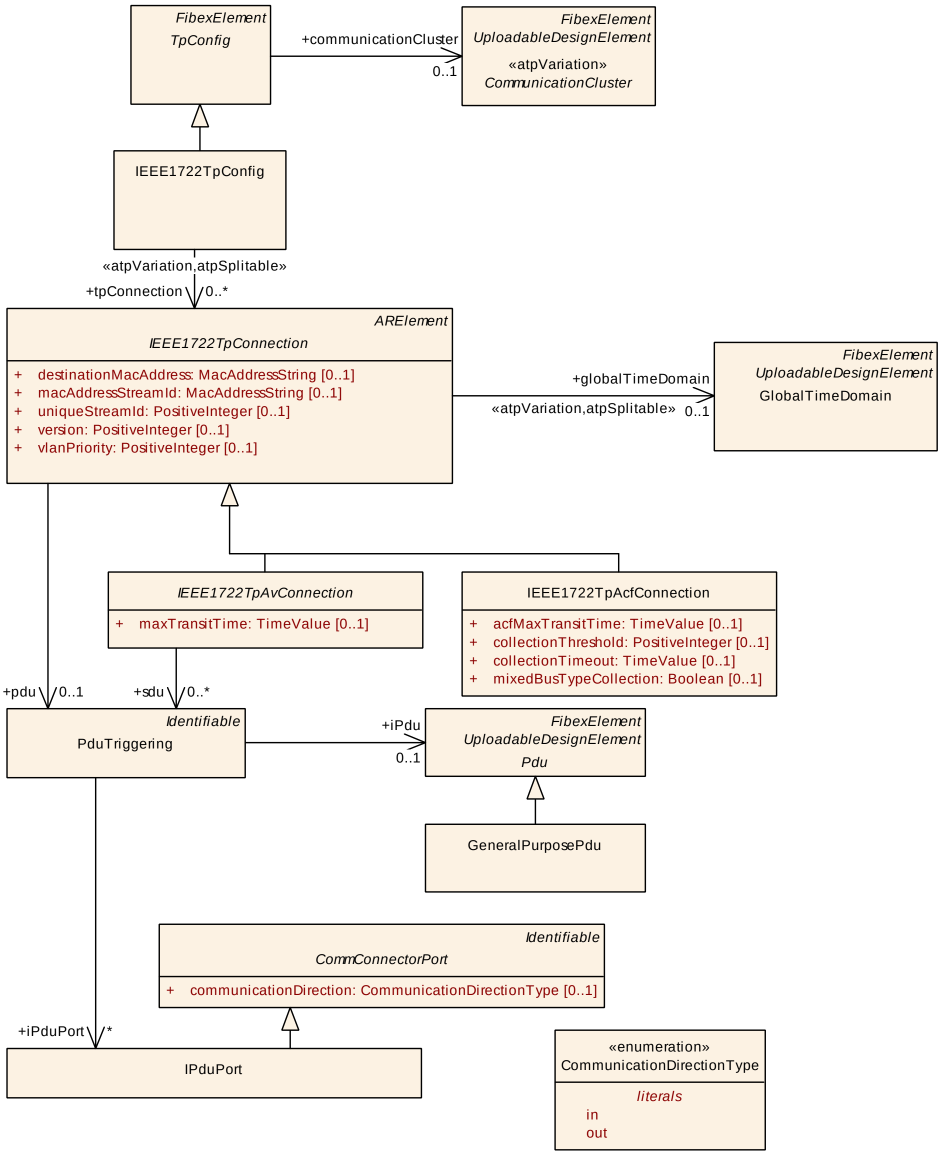

Figure 6.82: Modeling of IEEE1722TpConnection

The packet identification (Stream Id) is defined by the two attributes macAddressStreamId and uniqueStreamId.

[TPS_SYST_03098] IEEE1722Tp Stream Id definition

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The attributes IEEE1722TpConnection.macAddressStreamId and IEEE1722TpConnection.uniqueStreamId are concatenated to form the stream_id [35] value for an IEEE1722Tp message.⌋

[constr_3743] Allowed values for IEEE1722TpConnection.uniqueStreamId

Status: DRAFT
Imposition time: IT_SysDesc

⌈The value for IEEE1722TpConnection.uniqueStreamId shall be in the range between 0 and 65535.⌋

[constr_3747] Existence of attribute IEEE1722TpConnection.uniqueStreamId

Status: DRAFT
Imposition time: IT_SysDesc

⌈For each IEEE1722TpConnection, the attribute uniqueStreamId shall exist.⌋

[constr_3748] Existence of attribute IEEE1722TpConnection.macAddressStreamId

Status: DRAFT
Imposition time: IT_SysDesc

⌈For each IEEE1722TpConnection, the attribute macAddressStreamId shall exist.⌋

[TPS_SYST_03100] IEEE1722Tp destination MAC address definition

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈In case the IEEE1722Tp message is sent, then the destination MAC address is determined in one of two ways:

- explicitly using the IEEE1722TpConnection.destinationMacAddress definition,
- or, if destinationMacAddress is not defined, implicitly using the IEEE1722TpConnection.macAddressStreamId definition.

⌋

[TPS_SYST_03099] IEEE1722Tp Stream Version definition

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The attribute version defines the version [35] value for an IEEE1722Tp message.⌋

[constr_3744] Allowed values for IEEE1722TpConnection.version

Status: DRAFT
Imposition time: IT_SysDesc

⌈The value for IEEE1722TpConnection.version shall be in the range between 0 and 7.⌋

[constr_3749] Existence of attribute IEEE1722TpConnection.version

Status: DRAFT
Imposition time: IT_SysDesc

⌈For each IEEE1722TpConnection, the attribute version shall exist.⌋

The reference IEEE1722TpConnection.pdu refers to a PduTriggering which in turn refers to a GeneralPurposePdu of category IEEE1722TP, This GeneralPurposePdu is used for the transport of all the IEEE1722Tp messages on a specific EthernetPhysicalChannel in one IPduPort.communicationDirection (either CommunicationDirectionType.in or CommunicationDirectionType.out) as defined by the PduTriggering. As the lower layers (below IEEE1722Tp) are not able to differentiate between different IEEE1722Tp messages (based on the Stream Id or other IEEE1722Tp specific criteria) only one GeneralPurposePdu of category IEEE1722TP per EthernetPhysicalChannel and communicationDirection is required and supported.

[constr_3745] category of GeneralPurposePdu referenced in the role IEEE1722TpConnection.pdu

Status: DRAFT
Imposition time: IT_EcuExt

⌈The GeneralPurposePdu referenced by the PduTriggering which in turn is referenced in the role pdu by the IEEE1722TpConnection shall have the category set to IEEE1722TP.⌋

[constr_3750] Existence of attribute IEEE1722TpConnection.pdu

Status: DRAFT
Imposition time: IT_EcuExt

⌈For each IEEE1722TpConnection, the reference pdu shall exist.⌋

[TPS_SYST_03109] Transmission of an IEEE1722TpConnection

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈If the IEEE1722TpConnection references a PduTriggering in role pdu and that PduTriggering refers to an IPduPort (in the context of an EcuInstance) in the role iPduPort with communicationDirection set to CommunicationDirectionType.out,

then the IEEE1722TpConnection is transmitted by that EcuInstance.⌋

In the IEEE1722Tp context [35] a transmitting EcuInstance (according to [TPS_SYST_03109]) is also called a talker or producer.

[TPS_SYST_03110] Reception of an IEEE1722TpConnection

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈If the IEEE1722TpConnection references a PduTriggering in role pdu and that PduTriggering refers to an IPduPort (in the context of an EcuInstance) in the role iPduPort with communicationDirection set to CommunicationDirectionType.in,

then the IEEE1722TpConnection is received by that EcuInstance.⌋

In the IEEE1722Tp context [35] a receiving EcuInstance (according to [TPS_SYST_03110]) is also called a listener or consumer.

Table 6.285: IEEE1722TpAafAes3DataTypeEnum

An example of an IEEE1722TpAafConnection is illustrated in figure 6.87.

The IEEE1722TpAafConnection defines the audio stream credentials for this AAF stream.

In figure 6.87 the producer part of the IEEE1722TpAafConnection is shown. This is recognizable because the IEEE1722TpAafConnection refers to an PduTriggering *ProducerTransportPduTriggering* in the role pdu and that PduTriggering refers to an IPduPort *ProducerPort* that has the communicationDirection defined as CommunicationDirectionType.out.

During runtime the producer software will create the content of the *StreamPdu* and pass it to the IEEE1722Tp module. The IEEE1722Tp is able to match the GeneralPurposePdu *StreamPdu* with this IEEE1722TpAafConnection and will create the header of the IEEE1722Tp message according to the configuration details given in *AafConnection*. The IEEE1722Tp message is then handed to the Ethernet stack as the GeneralPurposePdu *GPP_1722TpTransportPdu* for sending on the network.

Whether the actual stream data is copied or handled via DMA during this process is up to the hardware capabilities and the configuration of the IEEE1722Tp module.

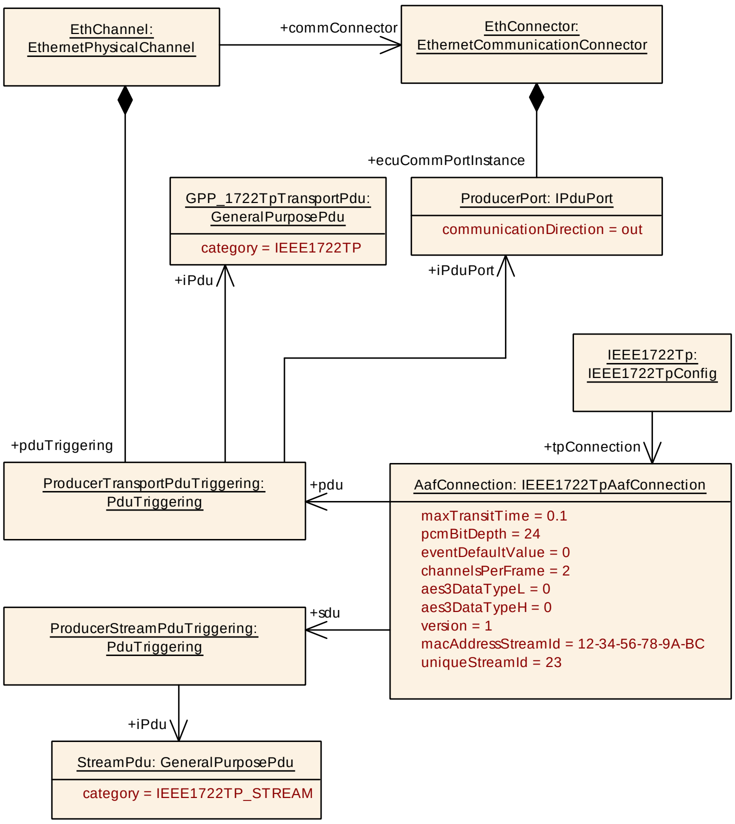

Figure 6.87: Example model of IEEE1722TpAafConnection producer

In figure 6.88 the same IEEE1722TpAafConnection is shown for the consumer part. Here the IPduPort *ConsumerPort* that has the communicationDirection defined as CommunicationDirectionType.in.

During runtime the IEEE1722Tp message is received and (due to the Ethertype for IEEE1722Tp) handed to the IEEE1722Tp module as GeneralPurposePdu *GPP_1722TpTransportPdu*. Based on the used stream id ([TPS_SYST_03098]) the IEEE1722Tp message is associated with this IEEE1722TpAafConnection and is indicated to the actual consumer software as GeneralPurposePdu *StreamPdu*.

Whether the actual stream data is copied or handled via DMA during this process is up to the hardware capabilities and the configuration of the IEEE1722Tp module.

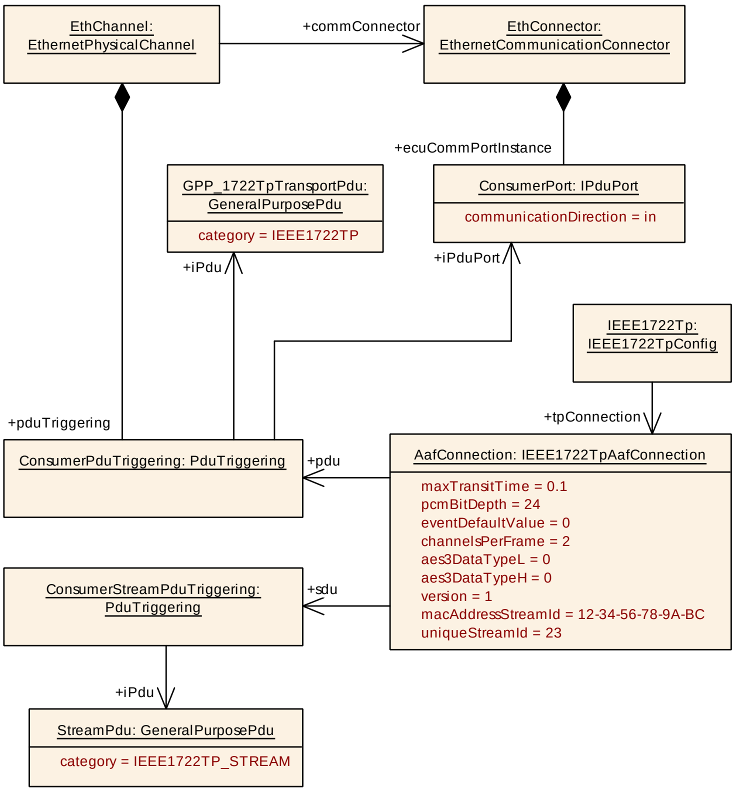

Figure 6.88: Example model of IEEE1722TpAafConnection consumer

6.8.12.4 Audio Video Transport IIDC

The AVTP IIDC format provides a mechanism for transporting audio and video data over an AVTP network.

The configuration details are shown in figure 6.89 and defined using IEEE1722TpIidcConnection.

Table 6.291: IEEE1722TpRvfFrameRateEnum

6.8.12.6 Control Data Transport

The AVTP Control Format (ACF) can be used to transport control messages (e.g. CAN or LIN messages) using an AVTP stream.

Note that in AUTOSAR `R23-11` this ACF transport feature is not fully supported yet, as parts of the AUTOSAR Basic software are not yet adapted for this transport.

Figure 6.91 shows an example of connecting two CAN nodes (*Node3* and *Node4*) via an *Ethernet Network*. CAN communication originating at *Node3* is sent on *CanCluster A* and received in *Node1*. *Node1* is also connected to the *Ethernet Network*. The `IEEE1722Tp` stream configuration in *Node1* can be set up to take the CAN messages of *CanCluster A* and put the CAN messages into an `IEEE1722Tp` ACF stream. *Node1* is the producer of that `IEEE1722Tp` ACF stream.

Node2 is the consumer of the `IEEE1722Tp` ACF stream. *Node2* takes the CAN messages from the stream and sends them on *CanCluster B* where the CAN messages can eventually be received by CAN *Node4*.

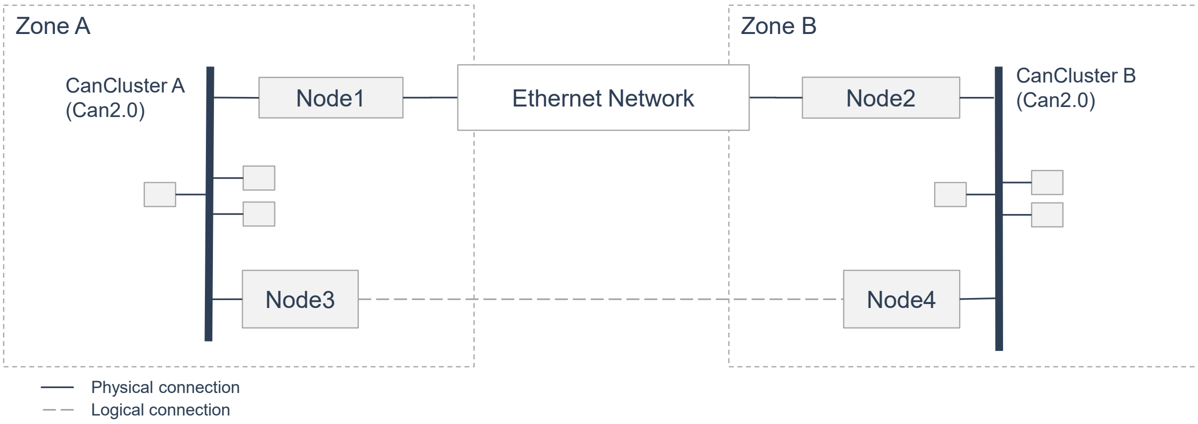

Figure 6.91: Example of IEEE1722Tp ACF stream transporting CAN messages

The IEEE1722TpAcfConnection may be configured to use either *Time-Synchronous Control Format* or *Non-Time-Synchronous Control Format*. This is defined by the existence of the attribute IEEE1722TpAcfConnection.acfMaxTransitTime.

[TPS_SYST_03116] Definition of Time-Synchronous Control Format

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈If the attribute IEEE1722TpAcfConnection.acfMaxTransitTime is defined, then the IEEE1722TpAcfConnection is transported using the *Time-Synchronous Control Format (TSCF)*.

If the attribute IEEE1722TpAcfConnection.acfMaxTransitTime is not defined, then the IEEE1722TpAcfConnection is transported using the *Non-Time-Synchronous Control Format (NTSCF)*.⌋

The IEEE1722TpAcfConnection defines an IEEE1722Tp stream which can transport control messages from one or multiple busses. Each transported bus is defined as an instance of IEEE1722TpAcfBus and is aggregated at the IEEE1722TpAcfConnection.acfTransportedBus.

Each transported bus defines a IEEE1722TpAcfBus.busId which is used to distinguish the potential multiple messages originating from different busses transported inside the IEEE1722Tp stream.

[constr_3751] Allowed values for IEEE1722TpAcfBus.busId

Status: DRAFT
Imposition time: IT_SysDesc

⌈The value for IEEE1722TpAcfBus.busId shall be in the range between 0 and 31.⌋

[constr_3752] Existence of attribute IEEE1722TpAcfBus.busId

Status: DRAFT
Imposition time: IT_SysDesc

⌈For each IEEE1722TpAcfBus, the attribute busId shall exist.⌋

[TPS_SYST_03102] Values of IEEE1722TpAcfBus.busId per bus system

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The values for IEEE1722TpAcfBus.busId are defined per bus system in the scope of one IEEE1722TpAcfConnection.

It is valid to define a transported IEEE1722TpAcfCan CAN bus with the identical busId value as a transported IEEE1722TpAcfLin LIN bus in the same IEEE1722TpAcfConnection. The bus kind in combination with the busId is used to distinguish the messages.⌋

The control messages that are put into one IEEE1722TpAcfConnection are typically much smaller than the size of one IEEE1722Tp ACF message. Thus a collection of several control messages into one IEEE1722Tp ACF message is supported. This may introduce a slight delay in the transport of individual control messages as the IEEE1722Tp ACF message is waiting to be filled with several control messages. The time for collection and the fill rate are defined according to [TPS_SYST_03101].

[TPS_SYST_03101] Collection of several control messages in one IEEE1722TpAcfConnection

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The attributes IEEE1722TpAcfConnection.collectionTimeout and IEEE1722TpAcfConnection.collectionThreshold control the collection behavior of the IEEE1722TpAcfConnection.⌋

If an individual control massage is put into the IEEE1722Tp ACF message it can be defined whether that specific control massage (defined as IEEE1722TpAcfBusPart) triggers the IEEE1722Tp ACF message to be sent immediately.

[TPS_SYST_03104] Triggering the immediate transmission of an IEEE1722Tp ACF message

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The attribute IEEE1722TpAcfBusPart.collectionTrigger defines whether that IEEE1722TpAcfBusPart triggers immediate sending of the IEEE1722Tp ACF message.⌋

6.8.12.7 Control Data Transport CAN

For the transport of CAN messages over an IEEE1722Tp ACF stream the definition of the IEEE1722TpAcfCan is used.

[TPS_SYST_03103] Abbreviated CAN message transport

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The attribute IEEE1722TpAcfCan.messageType defines whether the CAN messages shall be transported in an abbreviated format (IEEE1722TpAcfCanMessageTypeEnum.canBrief) or in an non-abbreviated format (IEEE1722TpAcfCanMessageTypeEnum.can) in the IEEE1722Tp ACF stream.⌋

[constr_3754] Existence of attribute IEEE1722TpAcfCan.messageType

Status: DRAFT
Imposition time: IT_SysDesc

⌈For each IEEE1722TpAcfCan, the attribute messageType shall exist.⌋

Which CAN messages are transported on an IEEE1722Tp ACF stream in the context of a dedicated IEEE1722TpAcfCan bus is defined using the IEEE1722TpAcfBus.acfPart aggregation.

[constr_3755] Consistend aggregation of IEEE1722TpAcfCanPart

Status: DRAFT
Imposition time: IT_SysDesc

⌈An IEEE1722TpAcfCan shall only aggregate IEEE1722TpAcfCanParts in the role IEEE1722TpAcfCan.acfPart.⌋

[TPS_SYST_03107] Definition of CAN message transport in IEEE1722Tp ACF stream

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈Each CAN message to be transported on an IEEE1722Tp ACF stream is defined by having a dedicated IEEE1722TpAcfCanPart and referring from that IEEE1722TpAcfCanPart to a PduTriggering in the role sdu. This PduTriggering defines which Pdu shall be transported via the iPdu reference.⌋

[TPS_SYST_03108] Definition of CAN Id in IEEE1722Tp ACF stream

Status: DRAFT
Upstream requirements: RS_SYST_00063

⌈The CAN Id to be used when transporting a CAN message on an IEEE1722Tp ACF stream is defined using the IEEE1722TpAcfCanPart.canIdentifier.⌋

[constr_3758] Allowed values for IEEE1722TpAcfCanPart.canIdentifier

Status: DRAFT
Imposition time: IT_SysDesc

⌈The value for IEEE1722TpAcfCanPart.canIdentifier shall be in the range between 0 and 536870911.⌋

The CAN basic software supports the definition if CAN Id range reception (CanFrameTriggering.rxIdentifierRange). Thus it is not required to define an individual Pdu in the ECU that handles the transport of the CAN messages in the IEEE1722Tp ACF stream (both transmission and reception) for every Pdu that is transported in the IEEE1722Tp ACF stream.

If the ECU is not interested in the content of a set of CAN messages (because this message is neither produced nor consumed at this ECU), then a whole range of CAN messages (based on their CAN Id) can be handled as one GeneralPurposePdu with category set to IEEE1722TP_ID_RANGE.

In case the CAN messages are received on a CAN bus at the ECU and transmitted in an IEEE1722Tp ACF stream, the range reception may be configured at the CanFrameTriggering. All CAN messages out of the defined rxIdentifierRange will be transported in an anonymous way as the GeneralPurposePdu of category IEEE1722TP_ID_RANGE. The actually CAN Id is then transported along the GeneralPurposePdu in its MetaData.

There is however a special case for the range based reception of CAN messages: If for a specific CAN Id which is in a defined CAN Id reception range rxIdentifierRange there exists also a dedicated reception defined with the CanFrameTriggering.identifier attribute, then this CAN message will only be handled in the specific Pdu. Such a CAN message will not be handled additionally as the GeneralPurposePdu of category IEEE1722TP_ID_RANGE. This behavior needs to be considered when defining which Pdus shall be put into an IEEE1722Tp ACF stream.

[constr_3759] Existence of attribute IEEE1722TpAcfCanPart.canIdentifier for IEEE1722Tp ACF stream transmission

Status: DRAFT
Imposition time: IT_SysDesc

⌈If an IEEE1722TpAcfCanPart is part of an IEEE1722TpAcfConnection which, according to [TPS_SYST_03109], is transmitted in that IEEE1722TpAcfConnection and the IEEE1722TpAcfCanPart refers to a PduTriggering in the role sdu which in turn refers to a Pdu that is NOT a GeneralPurposePdu of category IEEE1722TP_ID_RANGE,

then the attribute IEEE1722TpAcfCanPart.canIdentifier shall exist.⌋

In case the CAN messages are received as part of an IEEE1722Tp ACF stream at the ECU and shall be sent on a CAN bus, the range reception may be configured at the IEEE1722TpAcfCanPart. All CAN messages out of the defined canIdentifierRange will be transported in an anonymous way as the GeneralPurposePdu of category IEEE1722TP_ID_RANGE. The actually CAN Id is then transported along the GeneralPurposePdu in its MetaData.

[constr_3760] Existence of attribute IEEE1722TpAcfCanPart.canIdentifierRange or canIdentifierMask for IEEE1722Tp ACF stream reception

Status: DRAFT
Imposition time: IT_SysDesc

⌈If an IEEE1722TpAcfCanPart is part of an IEEE1722TpAcfConnection which, according to [TPS_SYST_03110], is received in that IEEE1722TpAcfConnection and

the IEEE1722TpAcfCanPart refers to a PduTriggering in the role sdu which in turn refers to a Pdu that is NOT a GeneralPurposePdu of category IEEE1722TP_ID_RANGE,

then the attribute IEEE1722TpAcfCanPart.canIdentifierRange or canIdentifierMask shall exist.⌋

Enumeration	**IEEE1722TpAcfCanMessageTypeEnum**
can	Defines the ACF CAN stream to use the ACF_CAN message type. **Tags:** atp.EnumerationLiteralIndex=0
canBrief	Defines the ACF CAN stream to use the ACF_CAN_BRIEF message type. **Tags:** atp.EnumerationLiteralIndex=1

Table 6.297: IEEE1722TpAcfCanMessageTypeEnum

In the example figure 6.94 two use cases are shown:

- local reception of a dedicated CAN message from a CanPhysicalChannel and the transport of that CAN message to an IEEE1722Tp ACF stream
- transport of a CAN Id message range from a CanPhysicalChannel to an IEEE1722Tp ACF stream.

The local reception is defined to be a CAN message with the CAN identifier *23* and being configured to be handled as an ISignalIPdu *IndividualReceptionPdu* for further processing in this ECU (e.g. handling in the COM module).

Additionally that received ISignalIPdu is configured to be transmitted in the IEEE1722TpAcfConnection *AcfConnection* using the IEEE1722TpAcfCanPart.sdu reference. The message in the IEEE1722Tp ACF stream will be qualified with the busId *4* and the canIdentifier *23*. The transport in the IEEE1722Tp ACF stream will use the IEEE1722TpAcfCanMessageTypeEnum.canBrief format.

The transport of a CAN Id message range can be configured by first defining a CAN range reception using the CanFrameTriggering.rxIdentifierRange. This setup will put all CAN messages in the defined CAN Id range of *0* - *3000* into the GeneralPurposePdu *RangeReceptionPdu*. Additionally it is expected that the actual CAN identifier for a specific received CAN message will be put into the MetaData of that GeneralPurposePdu.

The GeneralPurposePdu *RangeReceptionPdu* is configured to be transmitted in the IEEE1722TpAcfConnection *AcfConnection* using the IEEE1722TpAcfCanPart.sdu reference. The message in the IEEE1722Tp ACF stream will be qualified with the busId *4* and will use the IEEE1722TpAcfCanMessageTypeEnum.canBrief format.

The actual CAN Id to be used when putting the CAN message into the IEEE1722Tp ACF stream is then taken from the MetaData of the GeneralPurposePdu. Therefore it is not required to define a canIdentifier at the IEEE1722TpAcfCanPart *RangeIdPart* of the IEEE1722TpAcfCan *AcfCan*.

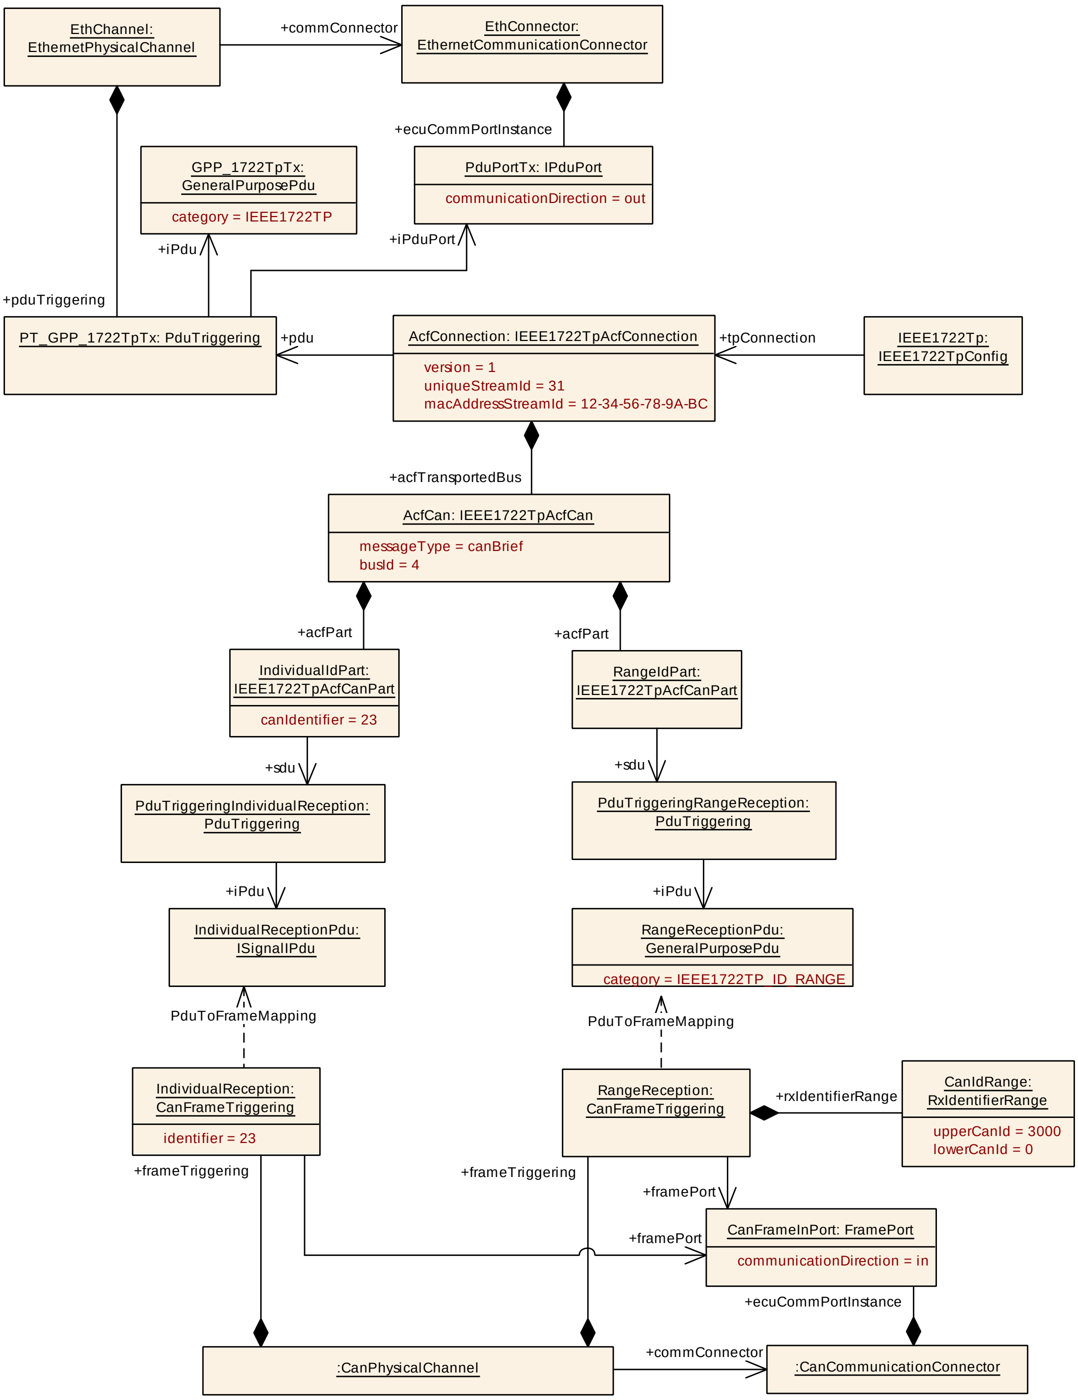

Figure 6.94: Example model of IEEE1722TpAcfCan transport

In the example figure 6.95 an ISignalIPdu is produced locally in this ECU and is sent to a CAN bus. This is configured in the lower part of the figure where the ISignalIPdu *LocalProducedPdu* is eventually mapped to a CanFrameTriggering (the mapping details are skipped here as they are not relevant for this use case). The ISignalIPdu is sent on the CanPhysicalChannel using the CAN identifier *7*.

Additionally to this transport on the CanPhysicalChannel the same ISignalIPdu *LocalProducedPdu* is configured to be transmitted in the

IEEE1722TpAcfConnection *AcfConnection* using the IEEE1722TpAcfCanPart.sdu reference. The message in the IEEE1722Tp ACF stream will be qualified with the busId *4* and the canIdentifier *7*. The transport in the IEEE1722Tp ACF stream will use the IEEE1722TpAcfCanMessageTypeEnum.canBrief format.

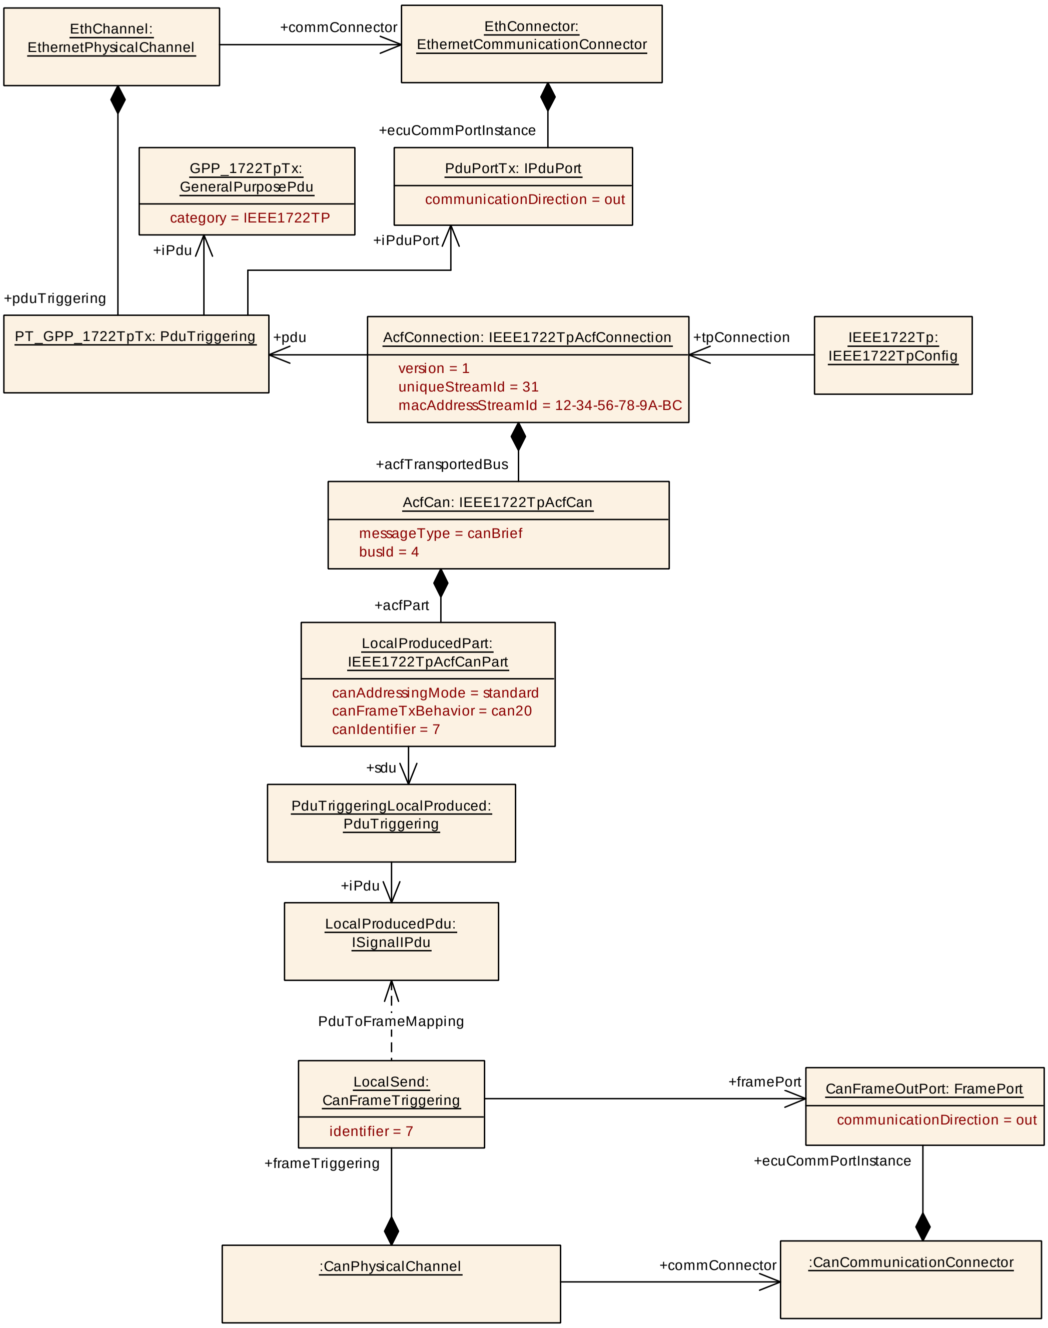

Figure 6.95: Example model of IEEE1722TpAcfCan transport of locally produced Pdu

6.8.12.8 Control Data Transport LIN

For the transport of LIN messages over an IEEE1722Tp ACF stream the definition of the IEEE1722TpAcfLin is used.

Which LIN messages are transported on an IEEE1722Tp ACF stream in the context of a dedicated IEEE1722TpAcfLin bus is defined using the IEEE1722TpAcfBus.acfPart aggregation.

6.9 Network Management

The NM specification of AUTOSAR consist of a Generic Network Management Interface Module and of bus specific Network management adaptation layers (CanNm, FrNm, UdpNm, J1939Nm). The AUTOSAR Generic NM Interface module acts as a bus-independent adaptation layer between the bus-specific Network Management modules and the AUTOSAR basic software module Communication Manager. The AUTOSAR Generic NM Interface module is represented by NmCluster, NmEcu, NmCoordinator and NmNode. The bus-specific Network Management attributes are represented by BusspecificNmEcu. See also figure 6.97.

[constr_5032] Maximal one NmConfig per System is allowed to be defined

Imposition time: IT_SysDesc

⌈Each System element is allowed to reference at most one NmConfig element with the fibexElement reference.⌋

[constr_3057] Maximal one BusspecificNmEcu per NmEcu and bus system is allowed to be defined

Imposition time: IT_SysDesc

⌈For each NmEcu, at most one BusspecificNmEcu per bus system (FlexRay/Can/Udp/J1939) is allowed to be defined.⌋

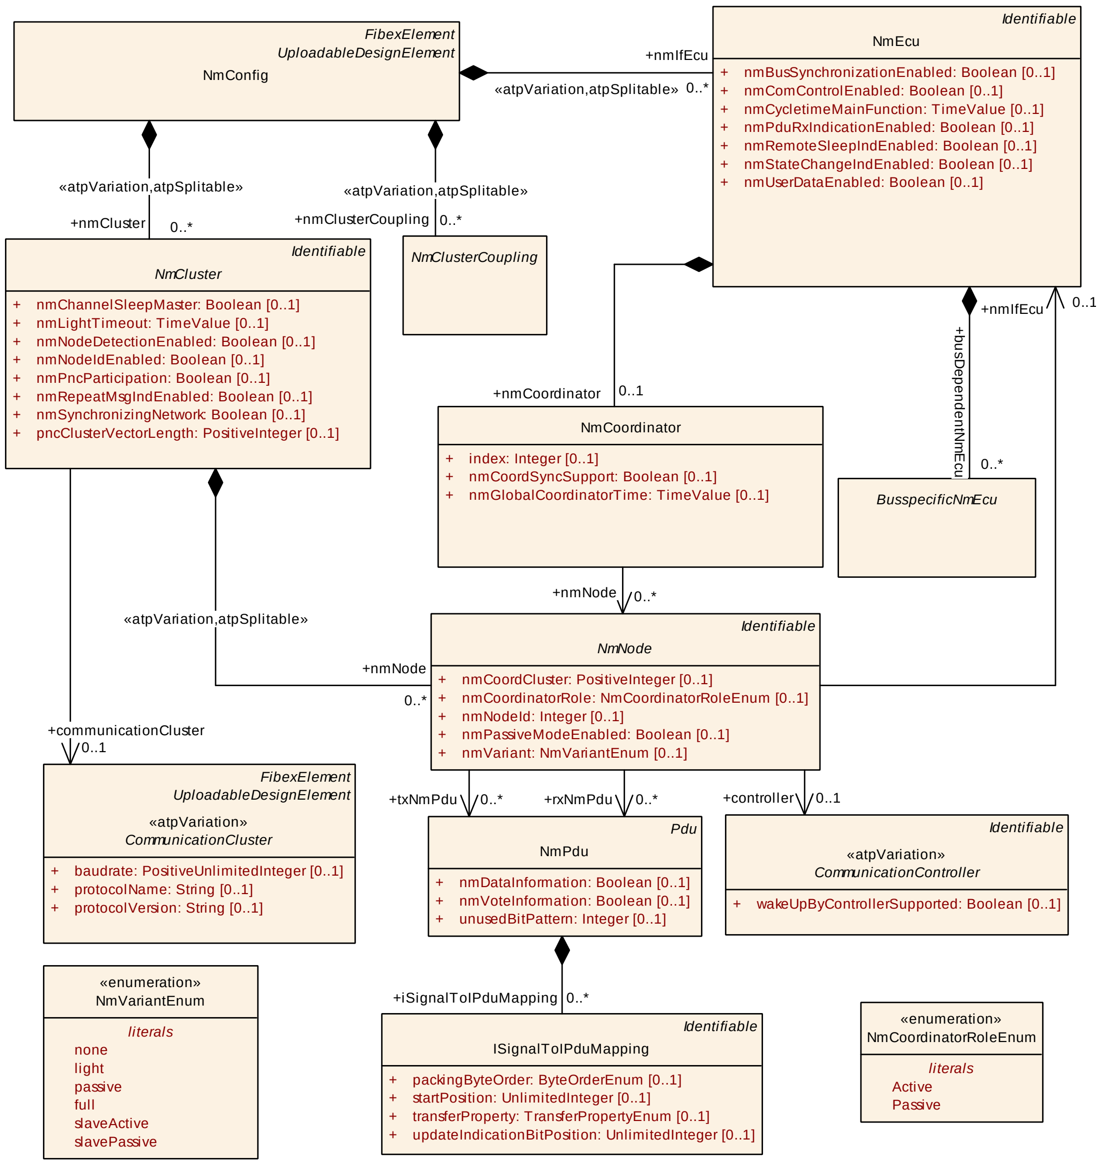

Figure 6.97: Generic Nm elements

The NmCluster contains a set of NmNodes.

The NmNodes are associated with the CommunicationController in the topology and belong to exactly one NmEcu. The reception and transmission of NmPdus is specified with the rxNmPdu and txNmPdu associations to NmPdus.

[TPS_SYST_01107] Definition of NmCoordinator ⌈An nmCoordinator is connected to two or more CommunicationClusters (via NmNodes) out of which at least two contain the requirement to shutdown synchronously.⌋

Aggregated by	NmConfig.nmCluster			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
communicationCluster	CommunicationCluster	0..1	ref	Association to a CommunicationCluster in the topology description.
nmChannelSleepMaster	Boolean	0..1	attr	This parameter shall be set to indicate if the sleep of this network can be absolutely decided by the local node only and that no other nodes can oppose that decision.
nmLightTimeout	TimeValue	0..1	attr	Defines the timeout (in seconds) after COMM_FULL_COMMUNICATION sub-state COMM_FULL_COM_READY_SLEEP is left.

▽

△

Class	*NmCluster* (abstract)			
nmNode	NmNode	*	aggr	Collection of NmNodes of the NmCluster. atpVariation: Derived, because NmNode can be variable. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=nmNode.shortName, nmNode.variationPoint.shortLabel vh.latestBindingTime=postBuild
nmNodeDetectionEnabled	Boolean	0..1	attr	Enables the Request Repeat Message Request support. Only valid if nmNodeIdEnabled is set to true.
nmNodeIdEnabled	Boolean	0..1	attr	Enables the source node identifier.
nmPncParticipation	Boolean	0..1	attr	Defines whether this NmCluster contributes to the partial network mechanism.
nmRepeatMsgIndEnabled	Boolean	0..1	attr	Switch for enabling the Repeat Message Bit Indication.
nmSynchronizingNetwork	Boolean	0..1	attr	If this parameter is true, then this network is a synchronizing network for the NM coordination cluster which it belongs to. The network is expected to call Nm_SynchronizationPoint() at regular intervals.
pncClusterVectorLength	PositiveInteger	0..1	attr	Optionally defines the length of the PNC Vector per CommunicationCluster (and VLAN in case of UdpNm). If not defined then System.pncVectorLength applies. Should only make the PNC Vector shorter (or same length as defined in System.pncVectorLength).

Table 6.301: NmCluster

[constr_3771] Range of NmCluster.nmLightTimeout

Imposition time: IT_SysDesc

⌈The value given for NmCluster.nmLightTimeout shall be in the range from 0 to 255.⌋

For the placement of user data in an NmPdu several boundaries and constraints have to be respected.

[TPS_SYST_03069] User data shall be defined within empty space of the NmPdu
⌈If user data is defined it shall be located within the not already used bounds of the NmPdu, specifically user data shall:

- not exceed NmPdu.length
- not be defined in the location where CBV and/or Nid are defined (nmCbvPosition and nmNidPosition are configured
- not be defined where the PncBitVector is located.

⌋

[TPS_SYST_03070] User data shall be before the PncBitVector or after the PncBitVector ⌈If NmCluster.nmPncParticipation is set to true then user data shall be placed either:

- between CBV (control bit vector) and PncBitVector or
- after the PncBitVector.

There shall not be two sections with user data in one NmPdu if PncBitVector (one before the PncBitVector and one after the PncBitVector).⌋

[TPS_SYST_03071] Available space of user data with PncBitVector ⌈If NmCluster.nmPncParticipation is set to true (i.e. partial network is enabled on that NmCluster) then user data may be defined in the range:

- if the user data is mapped between the NM system bytes (CBV, Nid) and the PncBitVector, then the size of user data range is determined by the difference between System.pncVectorOffset and the length of the system bytes (Nid, CBV).
- if the user data is mapped after the PncBitVector, then the size of user data range is determined by the difference between NmPdu.length and the last byte position of the PncBitVector.

⌋

[TPS_SYST_03072] Available space of user data without PncBitVector ⌈If NmCluster.nmPncParticipation is set to false (i.e. no partial network is enabled on that NmCluster) then user data may be defined in the range between the NM system bytes (CBV, Nid) and the end of the NmPdu. The size of user data range is determined by the difference between NmPdu.length and the length of the system bytes (Nid, CBV).⌋

[constr_3044] CBV configuration in case partial network is used

Imposition time: IT_SysDesc

⌈In case a partial network is used the control bit vector (CBV) shall be defined in Byte 0 of the NmPdu (nmCbvPosition = 0).⌋

[constr_3227] NmNode.nmPassiveModeEnabled setting

Imposition time: IT_SysDesc

⌈NmNode.nmPassiveModeEnabled shall be set to the same value in all NmClusters with the same bus protocol in the scope of one NmEcu.⌋

[constr_3767] NmNode.nmVariant setting to slavePassive

Imposition time: IT_SysDesc

⌈NmNode.nmVariant shall only be set to NmVariantEnum.slavePassive if an EthernetCommunicationController is referenced in the role NmNode.controller and the attribute slaveActAsPassiveCommunicationSlave in the referenced EthernetCommunicationController is set to true.⌋

[constr_3768] NmNode.nmVariant setting to slaveActive

Imposition time: IT_SysDesc

⌈NmNode.nmVariant shall only be set to NmVariantEnum.slaveActive if a LinSlave is referenced in the role NmNode.controller.⌋

6.9.2 CAN Network Management

The following class tables specify the configuration parameters of CAN Nm.

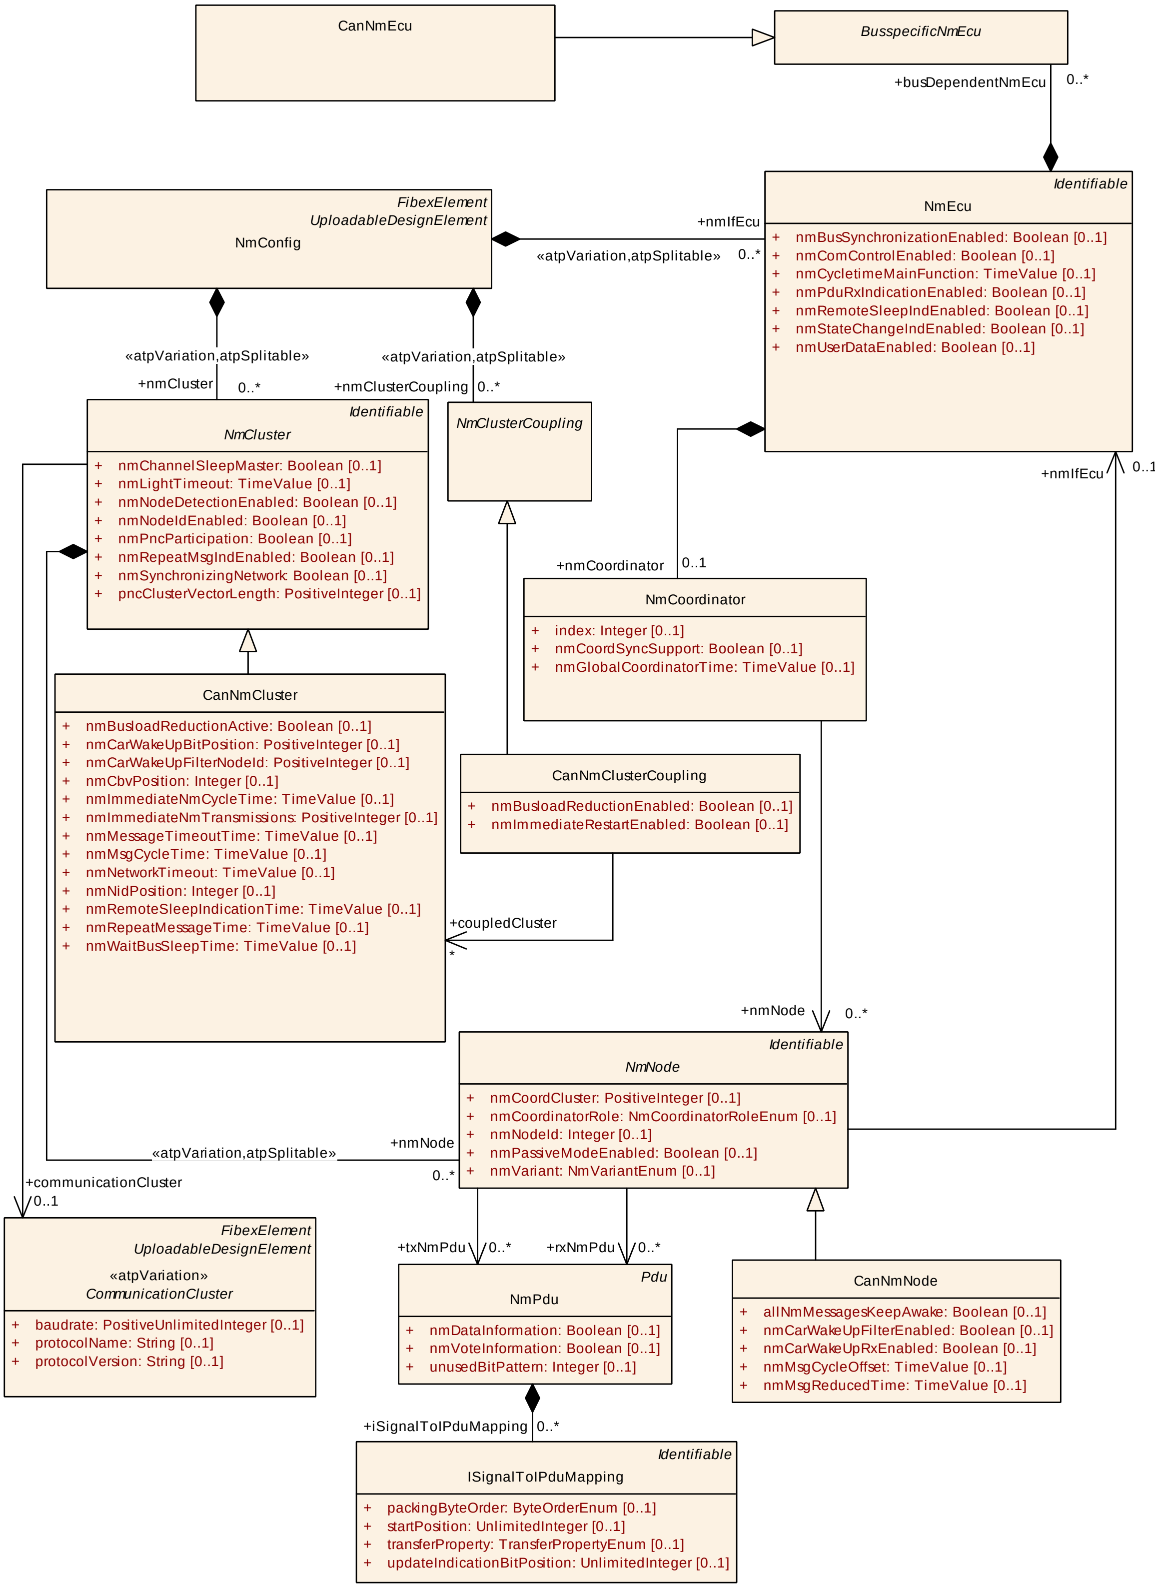

Figure 6.100: CAN Network Management Configuration (TransportProtocols: NmCan-Configuration)

Class	CanNmCluster			
Package	M2::AUTOSARTemplates::SystemTemplate::NetworkManagement			
Note	Can specific NmCluster attributes			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *NmCluster*, *Referrable*			
Aggregated by	NmConfig.nmCluster			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
nmBusload ReductionActive	Boolean	0..1	attr	It determines if bus load reduction for the respective Can Nm channel is active or not.
nmCarWakeUp BitPosition	PositiveInteger	0..1	attr	Specifies the bit position of the CarWakeUp within the Nm Pdu.
nmCarWakeUp FilterNodeId	PositiveInteger	0..1	attr	Source node identifier for CarWakeUp filtering.
nmCbvPosition	Integer	0..1	attr	Defines the position of the control bit vector within the Nm Pdu (Byte position). If this attribute is not configured, the Control Bit Vector is not used.
nmImmediate NmCycleTime	TimeValue	0..1	attr	Defines the immediate NmPdu cycle time in seconds which is used for nmImmediateNmTransmissions NmPdu transmissions. This parameter is only valid if CanNm ImmediateNmTransmissions is greater one.
nmImmediate Nm Transmissions	PositiveInteger	0..1	attr	Defines the number of immediate NmPdus which shall be transmitted. If the value is zero no immediate NmPdus are transmitted. The cycle time of immediate NmPdus is defined by nmImmediateNmCycleTime.
nmMessage TimeoutTime	TimeValue	0..1	attr	Timeout of an NmPdu in seconds. It determines how long the NM shall wait with notification of transmission failure while communication errors occur on the bus.
nmMsgCycle Time	TimeValue	0..1	attr	Period of a NmPdu in seconds. It determines the periodic rate in the periodic transmission mode with bus load reduction and is the basis for transmit scheduling in the periodic transmission mode without bus load reduction.
nmNetwork Timeout	TimeValue	0..1	attr	Network Timeout for NmPdus in seconds It denotes the time how long the CanNm shall stay in the Network Mode before transition into Prepare Bus-Sleep Mode shall take place.
nmNidPosition	Integer	0..1	attr	Defines the byte position of the source node identifier within the NmPdu. If this attribute is not configured, the Node Identification is not used.
nmRemote SleepIndication Time	TimeValue	0..1	attr	Timeout for Remote Sleep Indication in seconds. It defines the time how long it shall take to recognize that all other nodes are ready to sleep.
nmRepeat MessageTime	TimeValue	0..1	attr	Timeout for Repeat Message State in seconds. Defines the time how long the NM shall stay in the Repeat Message State.
nmWaitBus SleepTime	TimeValue	0..1	attr	Timeout for bus calm down phase in seconds. It denotes the time how long the CanNm shall stay in the Prepare Bus-Sleep Mode before transition into Bus-Sleep Mode shall take place.

allNmMessages KeepAwake	Boolean	0..1	attr	Specifies if Nm drops irrelevant NM PDUs. false: Only NM PDUs with a Partial Network Information Bit (PNI) = true and containing a Partial Network request for this ECU trigger the standard RX indication handling and thus keep the ECU awake true: Every NM PDU triggers the standard RX indication handling and keeps the ECU awake
nmCarWakeUp FilterEnabled	Boolean	0..1	attr	If this attribute is set to true the CareWakeUp filtering is supported.
nmCarWakeUp RxEnabled	Boolean	0..1	attr	If set to true this attribute enables the support of CarWake Up bit evaluation in received NmPdus.
nmMsgCycle Offset	TimeValue	0..1	attr	Node specific time offset in the periodic transmission node. It determines the start delay of the transmission. Specified in seconds.
nmMsg ReducedTime	TimeValue	0..1	attr	Node specific bus cycle time in the periodic transmission mode with bus load reduction. Specified in seconds.

Table 6.316: CanNmNode

6.9.3 UDP Network Management

The UPD Nm model is similar to the Nm models of the other communication buses but there are some specific characteristics due to the modeling of EthernetCluster and EthernetPhysicalChannel (see also chapter 3.3.6).

The UdpNmCluster corresponds to one EthernetPhysicalChannel (VLAN). Therefore it is required that for each EthernetPhysicalChannel on one EthernetCluster a respective UdpNmCluster with a reference to the EthernetPhysicalChannel is created. All of these UdpNmClusters point to the same EthernetCluster which the EthernetPhysicalChannels are contained in.

Thus, additionally to the reference from NmCluster to the CommunicationCluster (which applies to all Nm models), there is need for an Ethernet specific reference from the UdpNmCluster to the EthernetPhysicalChannel. This allows to specify for which VLAN this UdpNmCluster applies.

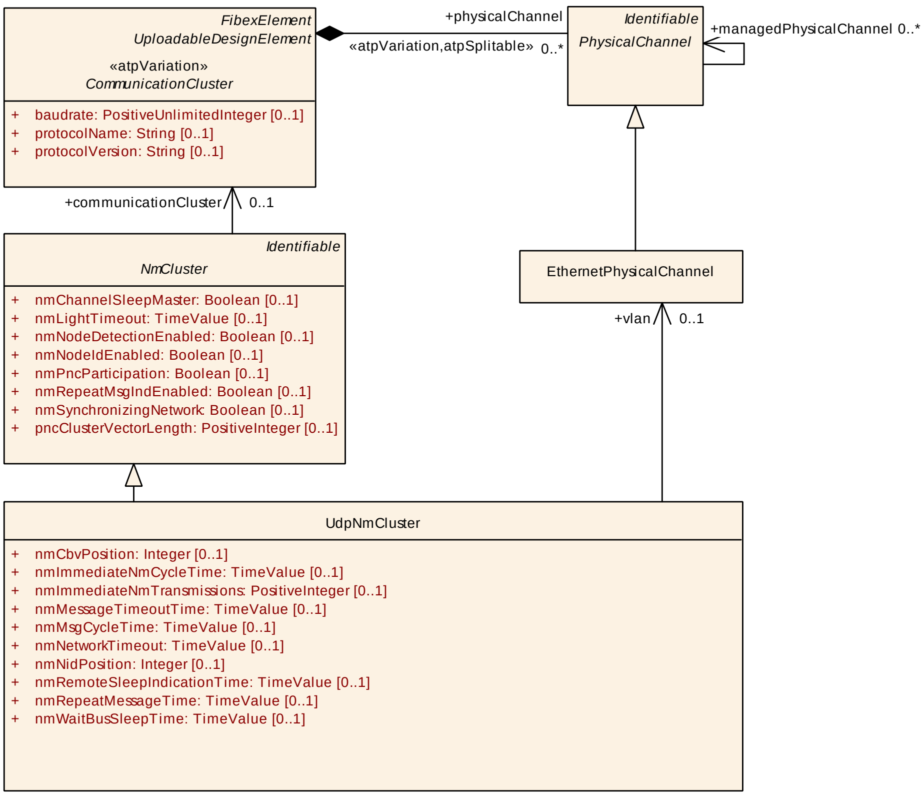

Figure 6.101: UdpNmCluster structure

The following class tables specify the configuration parameters of UDP Nm.

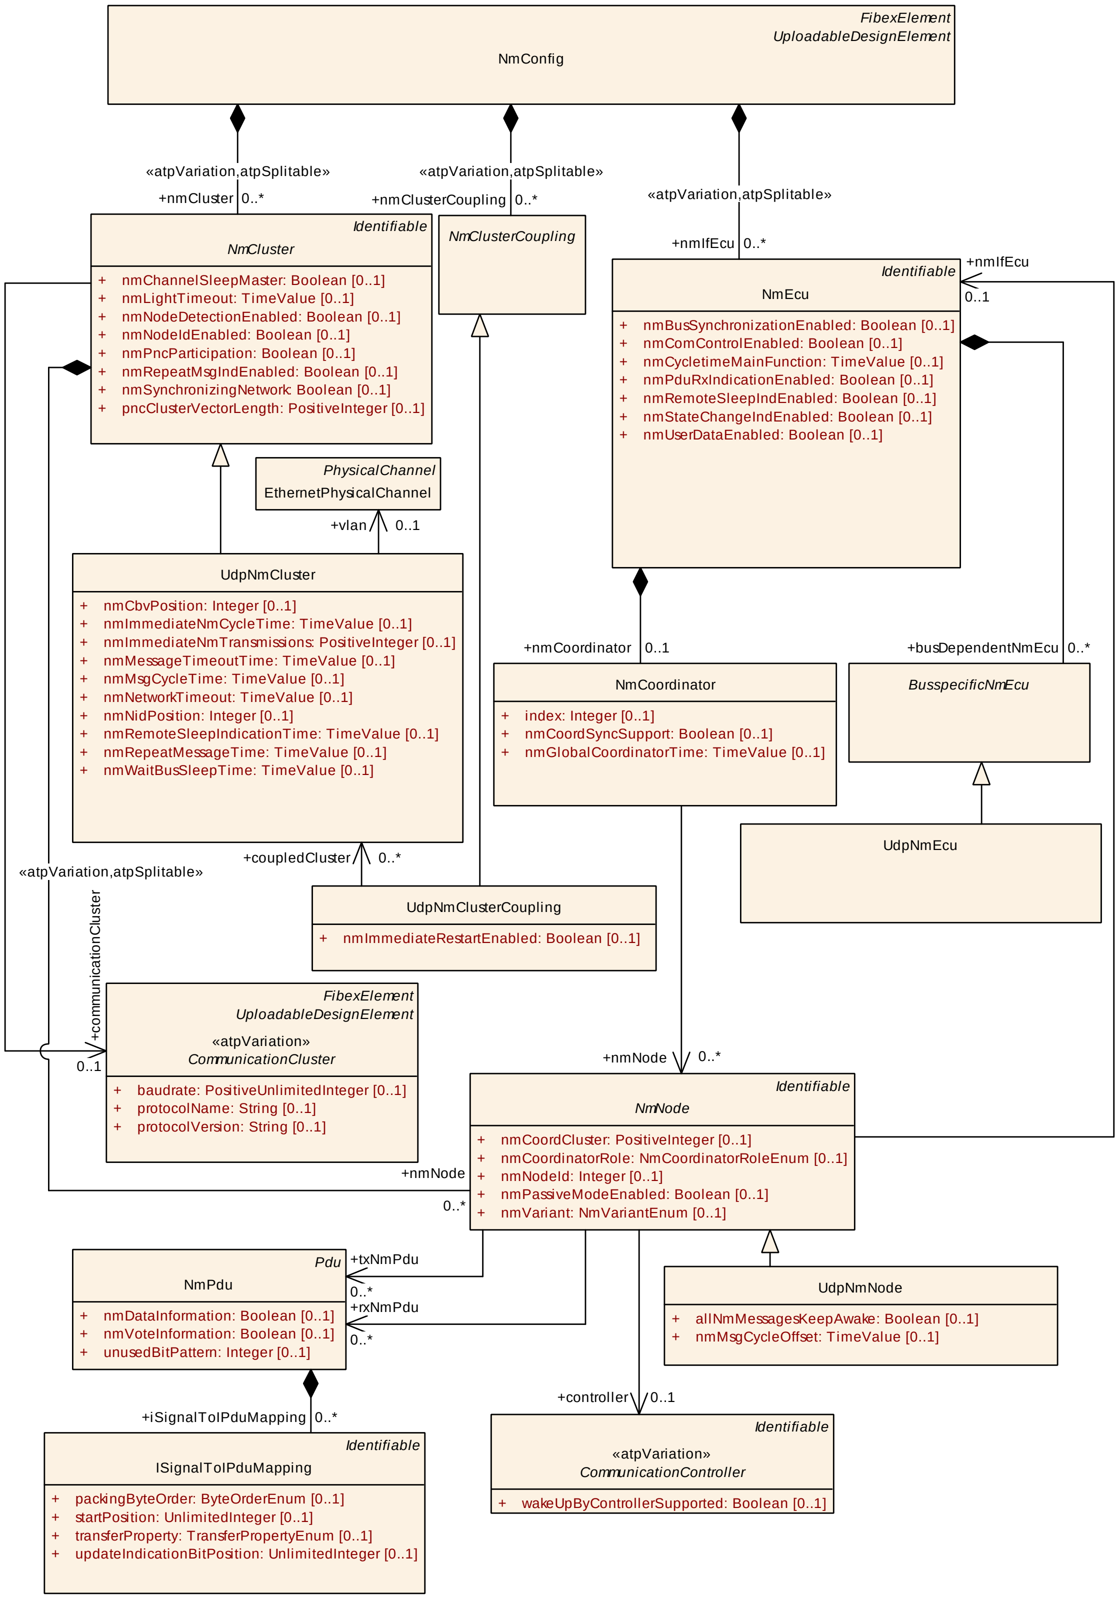

Figure 6.102: UDP Network Management Configuration (TransportProtocols: NmUdp-Configuration)

Class	UdpNmCluster

Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *NmCluster*, *Referrable*			
Aggregated by	NmConfig.nmCluster			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
nmCbvPosition	Integer	0..1	attr	Defines the position of the control bit vector within the Nm Pdu (Byte position). If this attribute is not configured, the Control Bit Vector is not used.
nmImmediate NmCycleTime	TimeValue	0..1	attr	Defines the immediate NmPdu cycle time in seconds which is used for nmImmediateNmTransmissions NmPdu transmissions. This attribute is only valid if nmImmediate NmTransmissions is greater one.
nmImmediate Nm Transmissions	PositiveInteger	0..1	attr	Defines the number of immediate NmPdus which shall be transmitted. If the value is zero no immediate NmPdus are transmitted. The cycle time of immediate NmPdus is defined by nmImmediateNmCycleTime.
nmMessage TimeoutTime	TimeValue	0..1	attr	Timeout of a NmPdu in seconds. It determines how long the NM shall wait with notification of transmission failure while communication errors occur on the bus.
nmMsgCycle Time	TimeValue	0..1	attr	Period of a NmPdu in seconds. It determines the periodic rate in the periodic transmission mode with bus load reduction and is the basis for transmit scheduling in the periodic transmission mode without bus load reduction.
nmNetwork Timeout	TimeValue	0..1	attr	Network Timeout for NmPdus in seconds. It denotes the time how long the UdpNm shall stay in the Network Mode before transition into Prepare Bus-Sleep Mode shall take place.
nmNidPosition	Integer	0..1	attr	Defines the byte position of the source node identifier within the NmPdu. If this attribute is not configured, the Node Identification is not used.
nmRemote SleepIndication Time	TimeValue	0..1	attr	Timeout for Remote Sleep Indication in seconds. It defines the time how long it shall take to recognize that all other nodes are ready to sleep.
nmRepeat MessageTime	TimeValue	0..1	attr	Timeout for Repeat Message State in seconds. Defines the time how long the NM shall stay in the Repeat Message State.
nmWaitBus SleepTime	TimeValue	0..1	attr	Timeout for bus calm down phase in seconds. It denotes the time how long the CanNm shall stay in the Prepare Bus-Sleep Mode before transition into Bus-Sleep Mode shall take place.
vlan	EthernetPhysical Channel	0..1	ref	Reference to the vlan (represented by the Ethernet PhysicalChannel) this UdpNmCluster shall apply to.

Table 6.326: J1939SharedAddressCluster

[TPS_SYST_02107] Shared address space for J1939 routing relations

Upstream requirements: RS_SYST_00038

⌈Address claims are routed between several CommunicationClusters independent of whether there are actual routings between individual nodes on respective CommunicationClusters. This means that the overall number of nodes in the shared CommunicationCluster cannot exceed 254, independently of the routing relations.⌋

[TPS_SYST_02108] Address proxying for J1939 routing relations

Upstream requirements: RS_SYST_00038

⌈The gateway claims all addresses used in routed messages on those CommunicationClusters to which the actual nodes are not connected. Thereby the address spaces are separate and only the nodes participating in a routing appear on more than one CommunicationCluster. The total number of nodes in the participating CommunicationClusters can be higher than 254, and the address arbitration is faster with less conflicts.⌋

[TPS_SYST_02109] Absence of participatingJ1939Cluster to a J1939Cluster

Upstream requirements: RS_SYST_00038

⌈If J1939Clusters exist that participate in a routing relation but are not referenced in the role J1939SharedAddressCluster.participatingJ1939Cluster by the same J1939SharedAddressCluster then gateway shall apply the address proxying according to [TPS_SYST_02108].⌋

6.9.5 Managed Channels

6.9.5.1 Ethernet VLANs

There is the use case to transmit NM frames on one VLAN (EthernetPhysicalChannel) and the application data on different VLANs. At the same time it shall be possible to indicate that a VLAN uses Network Management although no NmPdus are defined on this channel.

A reference between PhysicalChannels is used to express such a setting: The managing PhysicalChannel that contains configured NmPdus references PhysicalChannels in the role managedPhysicalChannel.

Since the reference managedPhysicalChannel is available on the abstract PhysicalChannel element it is not only usable in case of UdpNm and VLANs but also for similar cases on other bus networks.

[constr_3479] PhysicalChannel is not allowed to be a managedPhysicalChannel and a managing PhysicalChannel

Imposition time: IT_SysDesc

⌈If a PhysicalChannel is referenced in role managedPhysicalChannel, then it shall not be the source of another managedPhysicalChannel relation.⌋

[constr_3480] PhysicalChannel shall be referenced in the role managedPhysicalChannel only once

Imposition time: IT_SysDesc

⌈A PhysicalChannel shall be referenced in the role managedPhysicalChannel only up to once.⌋

[constr_3481] UdpNmCluster is not allowed to reference a managedPhysicalChannel in the role vlan

Imposition time: IT_SysDesc

⌈If an EthernetPhysicalChannel is target of a managedPhysicalChannel reference, then no UdpNmCluster shall reference this managedPhysicalChannel in the role vlan.⌋

[constr_3482] NmCluster is not allowed to reference a CommunicationCluster that aggregates a managedPhysicalChannel

Imposition time: IT_SysDesc

⌈If a PhysicalChannel, except EthernetPhysicalChannel, is target of a managedPhysicalChannel, then the aggregating CommunicationCluster shall not be referenced by any NmCluster in the role communicationCluster.⌋

6.9.5.2 Ethernet tunneling through CAN XL

For the use case of tunneling Ethernet frames through CAN XL (see Ch. 3.3.1.2.2), the following specifics regarding network management configuration need to be observed:

[constr_3708] No UDP network management in case of Ethernet tunneling through CAN XL

Imposition time: IT_SysDesc

⌈For an EthernetPhysicalChannel that is connected to an EthernetCommunicationController of category CAN_XL (i.e. an EthernetPhysicalChannel tunneled through CAN XL), no UDP network management shall be configured.⌋

Instead, the tunneled EthernetPhysicalChannel is managed by the CAN network management of the tunneling CAN XL network. This needs to be defined in the managed channel relationship:

[TPS_SYST_03077] Managed channel in case of Ethernet tunneling through CAN XL ⌈If a CanPhysicalChannel belonging to a CAN XL network is configured to tunnel Ethernet frames, then managedPhysicalChannel.CanPhysicalChannel shall refer to the EthernetPhysicalChannel that represents the tunneled Ethernet network.⌋

6.10 Bus Mirroring

Many communication buses in a vehicle are not directly accessible by a tester. To allow a tester to listen to the traffic on such internal communication buses the bus mirroring is introduced. The bus mirroring collects traffic from such an internal communication bus and forwards it to an intermediate destination bus or to a destination bus that is accessible by the tester.

Testers connected via CAN will receive unmodified CAN frames and LIN frames with special CAN IDs. Testers connected via Ethernet will receive a stream containing current time, identification, and content of CAN, LIN, and FlexRay frames.

On intermediate FlexRay buses, a set of PDUs is used to transport streams of mirrored frames with the same layout as on Ethernet.

[TPS_SYST_02202] Modeling of bus mirroring ⌈The BusMirrorChannelMapping defines the bus mirroring in which the communication traffic of the sourceChannel is forwarded to the targetChannel.⌋

6.11 Fan-out

AUTOSAR supports three different fan-outs:

- Signal fan-out
- Pdu fan-out
- Frame fan-out

Note that the specification in this section does not apply for Client/Server communication. The respective details are described in section 5.2.1.3.

6.11.1 Signal fan-out

A Signal fan-out can either be RTE signal fan-out or COM Signal Gateway fan-out. The details are explained in the following subchapters.

6.11.1.1 RTE signal fan-out

The RTE supports a “signal fan-out” where two or more ISignals of the same SystemSignal are sent in multiple ISignalIPdus to potentially multiple receivers.

[TPS_SYST_01109] RTE signal fan-out support for a SystemSignal ⌈The RTE signal fan-out from a SystemSignal to multiple ISignals is enabled in the System Description if the following conditions apply:

- several ISignals reference the SystemSignal in the role systemSignal and
- the SystemSignal is not referenced by a SystemSignalGroup
- a DataMapping references the SystemSignal and
- the DataMapping references an element in a PPortPrototype and
- the ISignals are transmitted by the EcuInstance on which the RTE is running, i.e. an ISignalTriggering exists that references the ISignal in the role iSignal and references a ISignalPort of the EcuInstance with communicationDirection out.

⌋

Figure 6.110 shows a scenario where the RTE does not need to perform a fan-out since each SystemSignal is referenced by exactly one ISignal.

Please note that in all example scenarios that are shown in this chapter the ISignalToIPduMappings shall be modeled for each ISignal or ISignalGroup. For simplicity reasons, the following diagrams leave the ISignalToIPduMappings out and just assume that they exist.

In addition for simplicity reasons the examples scenarios are showing always one OUT EcuPort and/or one IN EcuPort. But the different ISignalTriggerings are also allowed to reference own ISignalPorts that are defined on the EcuInstance.

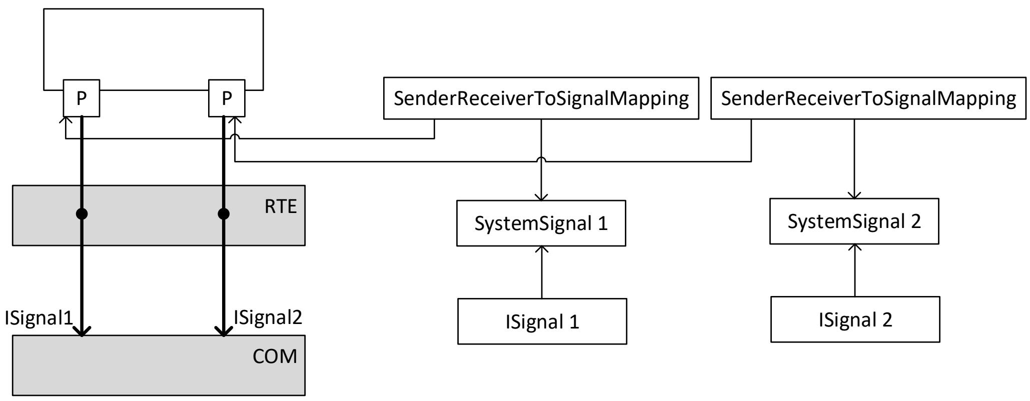

Figure 6.110: Scenario where RTE does not perform a fan-out

Figure 6.111 shows a scenario where the RTE needs to perform a fan-out since the SystemSignal is referenced by two ISignals, a SenderReceiverToSignalMapping is defined that maps a VariableDataPrototype in a SenderReceiverInterface of a PPortPrototype to the SystemSignal and the ISignals are both transmitted by the EcuInstance.

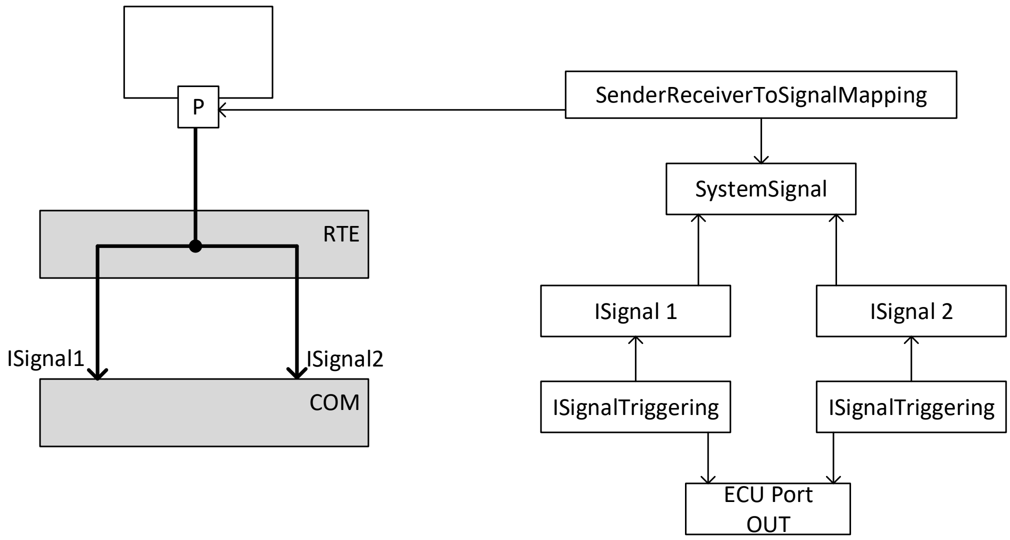

Figure 6.111: Scenario where RTE does perform a fan-out

Figure 6.112 shows a scenario where the RTE does not need to perform a fan-out since one of the ISignals that is referencing the SystemSignal is transmitted by the EcuInstance and the second ISignal is received. In addition the SenderReceiverToSignalMapping that references the SystemSignal references a VariableDataPrototype in a RPortPrototype and therefore [TPS_SYST_01109] is not fulfilled.

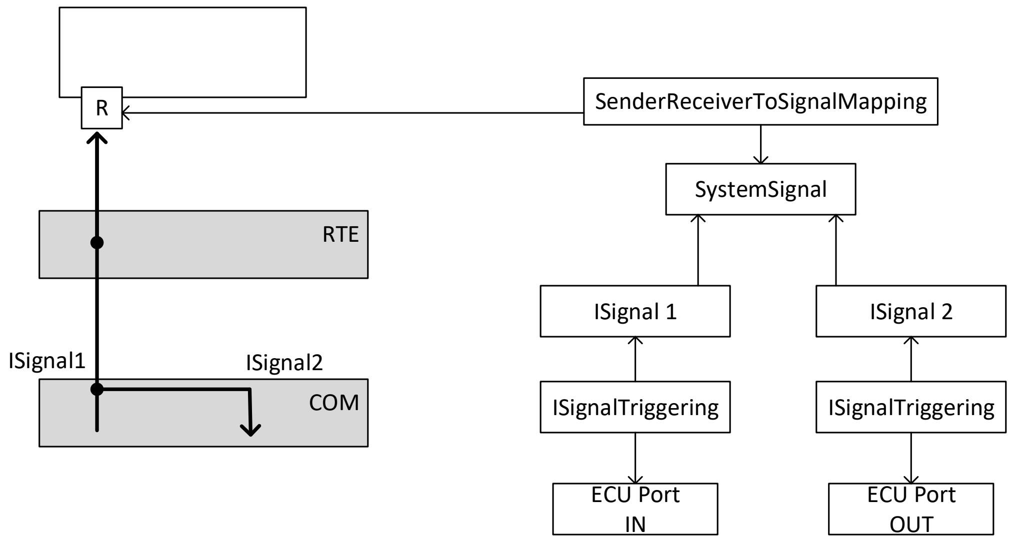

Figure 6.112: Scenario where RTE does not perform a fan-out since one ISignal is received and one is transmitted

[TPS_SYST_02309] RTE signal fan-out support for a SystemSignalGroup ⌈The RTE signal fan-out from a SystemSignalGroup to multiple ISignalGroups is enabled in the System Description if the following conditions apply:

- several ISignalGroups reference the SystemSignalGroup in the role systemSignalGroup and
- a DataMapping references the SystemSignalGroup and
- the DataMapping references an element in a PPortPrototype and
- each of the contained ISignals of the ISignalGroup refers to its corresponding SystemSignal which in turn is part of the SystemSignalGroup and
- the ISignalGroups are transmitted by the EcuInstance on which the RTE is running, i.e. an ISignalTriggering exists that references the ISignalGroup in the role iSignalGroup and references a ISignalPort of the EcuInstance with communicationDirection out.

⌋

In other words if two ISignalGroups reference the same SystemSignalGroup, but one of the ISignalGroups is received and one is transmitted no RTE signal fan-out is performed. Only if several ISignalGroups that are transmitted reference the same SystemSignalGroup the RTE signal fan-out is performed.

Figure 6.113 shows a scenario where the RTE needs to perform a fan-out since the SystemSignalGroup is referenced by two ISignalGroups, a SenderReceiverToSignalGroupMapping is defined that maps a VariableDataPrototype in a SenderReceiverInterface of a PPortPrototype to the SystemSignalGroup and both ISignalGroups are transmitted by the EcuInstance.

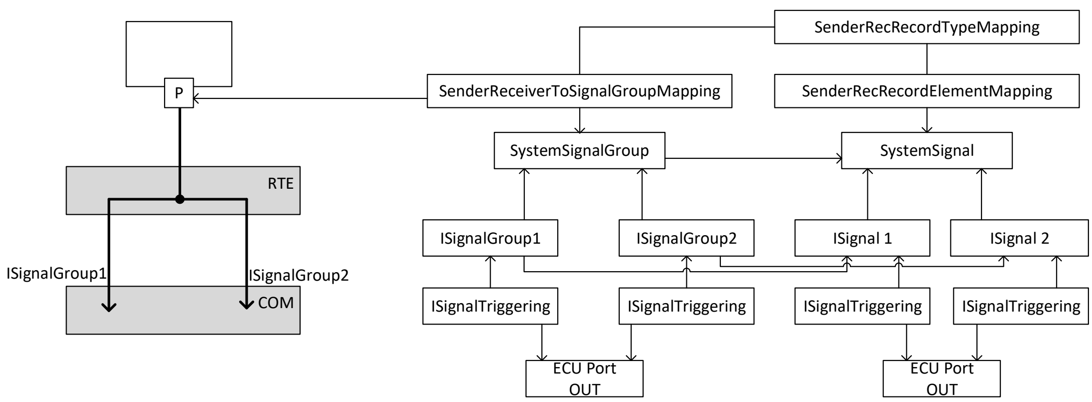

Figure 6.113: Scenario where RTE does perform a fan-out for a SystemSignalGroup

A combination of [TPS_SYST_01109] and [TPS_SYST_02309] is also supported, see also [TPS_SYST_01137] for the motivation of such a setup.

[TPS_SYST_03078] RTE signal fan-out support for a stand-alone SystemSignal out of a SystemSignalGroup ⌈The RTE signal fan-out of a SystemSignal inside a SystemSignalGroup to a stand-alone ISignal is enabled in the System Description if the following conditions apply:

- one or more ISignals reference the SystemSignal in the role systemSignal and
- the ISignals are not referenced by any ISignalGroup and
- a DataMapping references the SystemSignalGroup and
- the DataMapping references an element in a PPortPrototype and
- the ISignals are transmitted by the EcuInstance on which the RTE is running, i.e. an ISignalTriggering exists that references the ISignal in the role iSignal and references an ISignalPort of the EcuInstance with communicationDirection out.

⌋

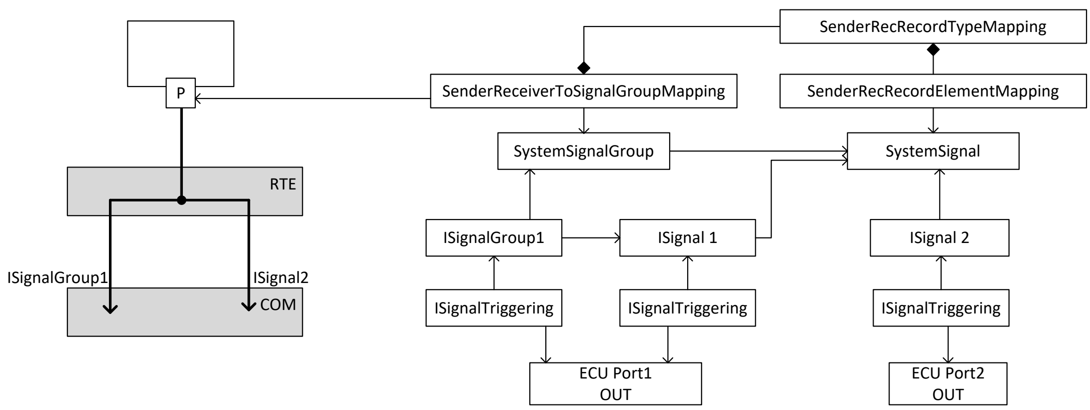

Figure 6.114: Scenario where RTE does perform a fan-out for a stand-alone SystemSignal out of a SystemSignalGroup

In the example in figure 6.114 the SystemSignal is part of a SystemSignalGroup and for that SystemSignalGroup a SenderReceiverToSignalGroupMapping is defined pointing to a PPortPrototype. Thus the application is able to send the payload of that SystemSignalGroup.

An ISignalGroup is defined referring to an ISignal (*ISignal1*) applicable for that SystemSignal. Thus [TPS_SYST_02309] applies and the SystemSignal will be sent as part of the SystemSignalGroup.

Also an ISignal applicable for the SystemSignal is defined (*ISignal2*), but *ISignal2* is not referenced by any ISignalGroup, thus it is intended to sent the SystemSignal as a standalone signal as well ([TPS_SYST_01109]).

6.11.1.2 COM Signal Gateway fan-out

In Com [21] the Signal Gateway supports a fan-out where an incoming signal is routed to several destinations.

[TPS_SYST_01110] Com Signal Gateway fan-out support ⌈A Signal Gateway fan-out (1:n routing) is described with the definition of several ISignalMappings in the Gateway description, which all refer to the same source ISignalTriggering.⌋

Note that [constr_3514] applies for the relation between ISignalToIPduMapping to ISignal.

Figure 6.115 shows a scenario where a Signal Gateway is defined in which the same source ISignalTriggering is mapped by two ISignalMappings to two dedicated target ISignalTriggerings. Since a DataMapping is not defined for the System-Signal that is referenced by the received and transmitted ISignals the RTE is not involved.

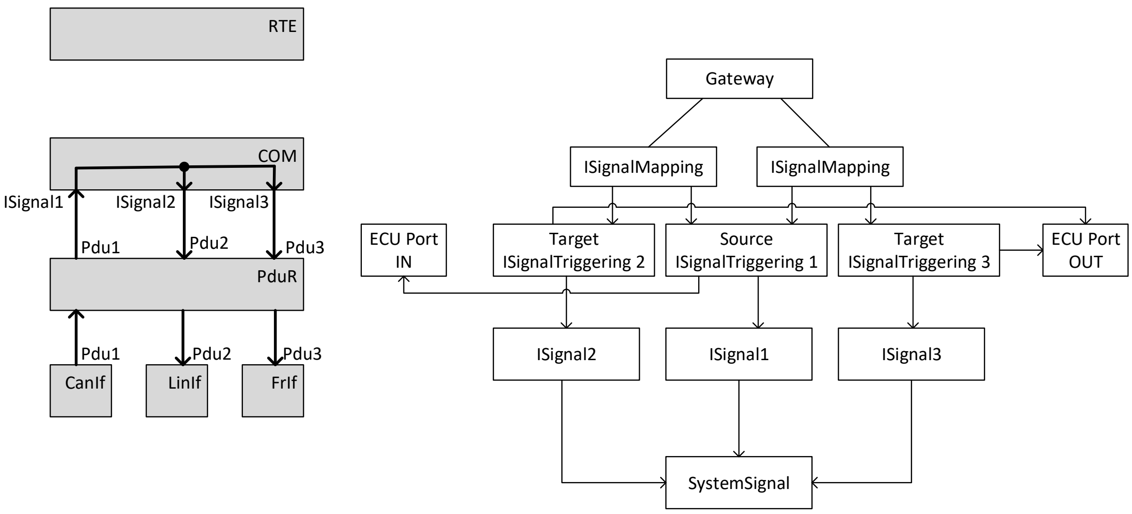

Figure 6.115: Scenario where the Com Gateway performs a fan-out and RTE is not involved

Figure 6.116 shows a scenario where a Signal Gateway is defined in which the same source ISignalTriggering is mapped by two ISignalMappings to two dedicated target ISignalTriggerings. A DataMapping is defined for the SystemSignal that is referenced by the received and transmitted ISignals. Therefore the RTE is involved. But the rule for the RTE signal fan-out (see [TPS_SYST_01109] does not apply since the DataMapping references an element in a RPortPrototype.

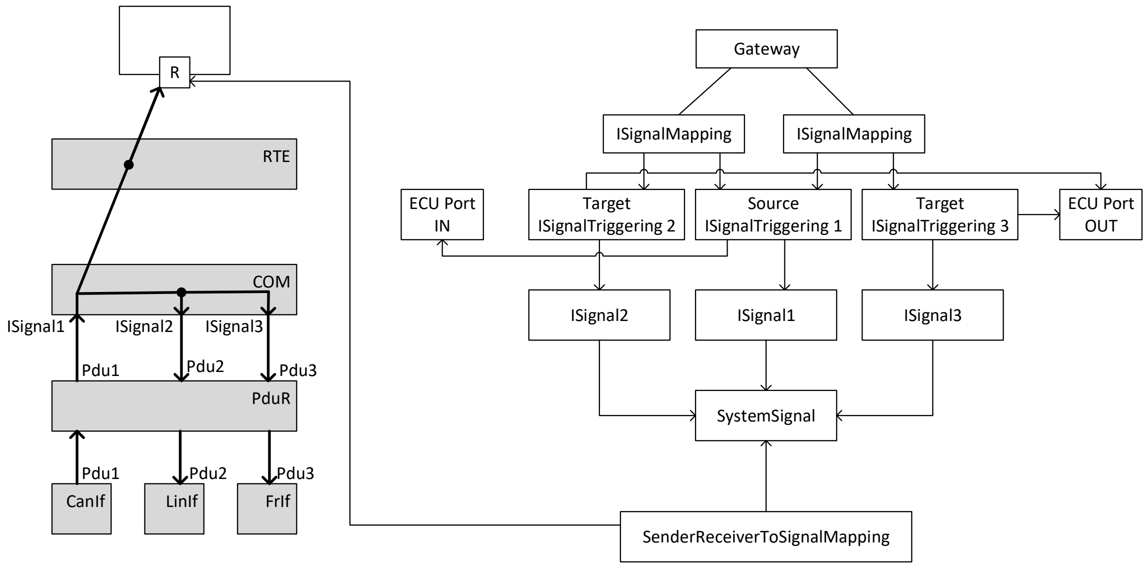

Figure 6.116: Scenario where the Com Gateway performs a fan-out and RTE is involved

6.11.2 Pdu fan-out

6.11.2.1 Pdu Router fan-out

The Pdu Router supports the "PDU fan-out" where one IPdu is sent to multiple destinations.

[TPS_SYST_01111] Pdu Router fan-out support ⌈The Pdu Router fan-out is described by several PduTriggering elements pointing to the same Pdu[3].

The sending ECU/PDU router has an output IPduPort that has the value of communicationDirection set to out and is referenced by the PduTriggering. According to the Cluster/Channel aggregation, the Pdu Router determines the clusters to use in its routing.⌋

[TPS_SYST_01112] FlexrayCluster Pdu Router interaction ⌈The following condition applies only in case of FlexRay on the same FlexrayCluster if two PduTriggerings refer to the same Pdu: this Pdu shall only be sent once to the FlexRay Interface. In other words the Pdu Router sends only one Pdu Transmission request to the FlexRay Interface.⌋

[3] AUTOSAR Layered Architecture [33] defines which Pdu types are routed by the Pdu Router

Several examples of various Pdu Router configurations are illustrated in the following section. In chapter 8.2.1 further examples of fan-out in combination with Pdu gateways are defined.

6.11.2.1.1 Pdu Router simple fan-out

The example in figure 6.117 shows a simple Pdu router fan-out where an ISignalIPdu is produced by the Com module and forwarded to the PduR. In the PduR a fan-out to two PhysicalChannels is performed.

For a simplified figure just one ISignal is shown to be part of the ISignalIPdu. Of course it is possible to define several ISignal being part of an ISignalIPdu.

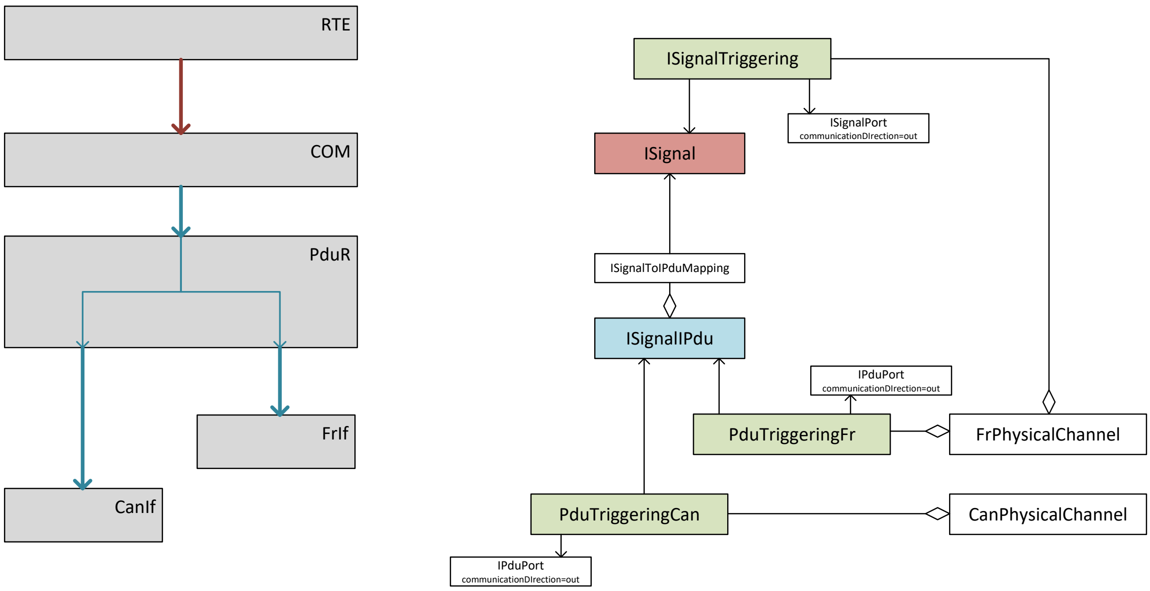

Figure 6.117: Pdu Router simple fan-out example

6.11.2.1.2 Pdu Router SecOC Pdu fan-out

In the example figure 6.118 the PduR takes an ISignalIPdu from the Com module and hands it over to the SecOC module. This is a plain forwarding operation (no fan-out involved here).

In the SecOC module a SecuredIPdu is created and handed back to the PduR. Then the PduR performs a fan-out to send the SecuredIPdu to two PhysicalChannels.

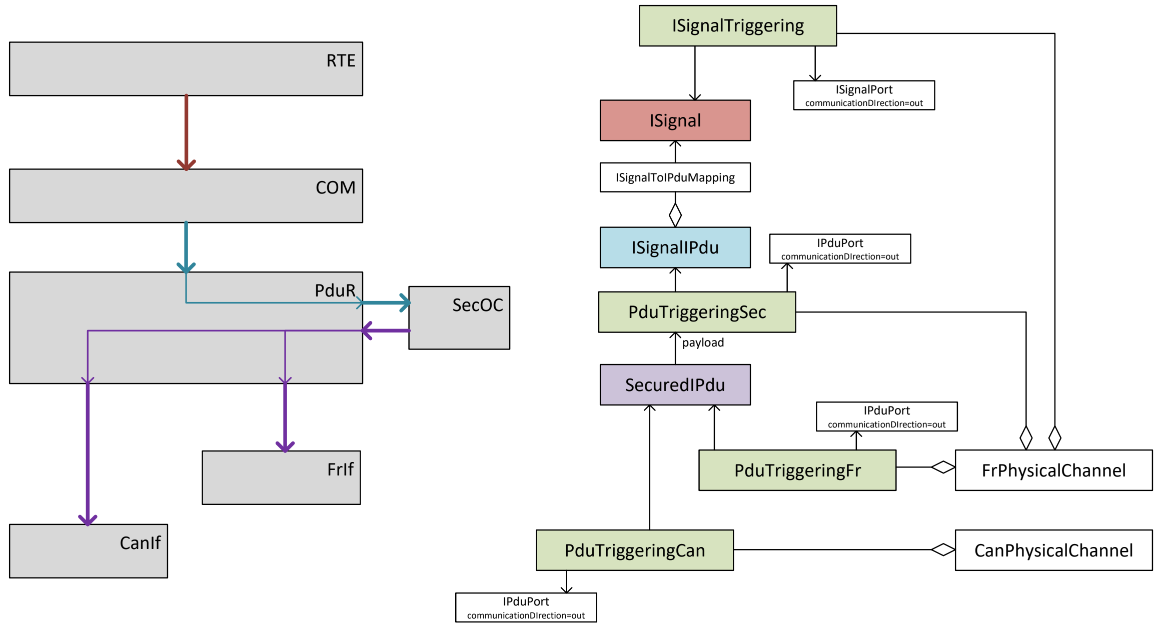

Figure 6.118: Pdu Router SecOC Pdu fan-out example

6.11.2.1.3 Pdu Router Container Pdu fan-out

In the example figure 6.119 the PduR takes one of several ISignalIPdus from the Com module and hands them over to the IpduM module. This is a plain forwarding operation (no fan-out involved here).

In the IpduM module a ContainerIPdu is created and handed back to the PduR. Then the PduR performs a fan-out to send the ContainerIPdu to two PhysicalChannels.

For a simplified figure just one ISignal is shown to be part of the *ISignalIPduB*. Of course also *ISignalIPduA* will have one or more ISignals defined as well.

Also *PduTriggeringContA* being owned by the *FrPhysicalChannel* is not shown, but will be part of the example model. As well as the reference from *PduTriggeringContA* to an IPduPort is not shown.

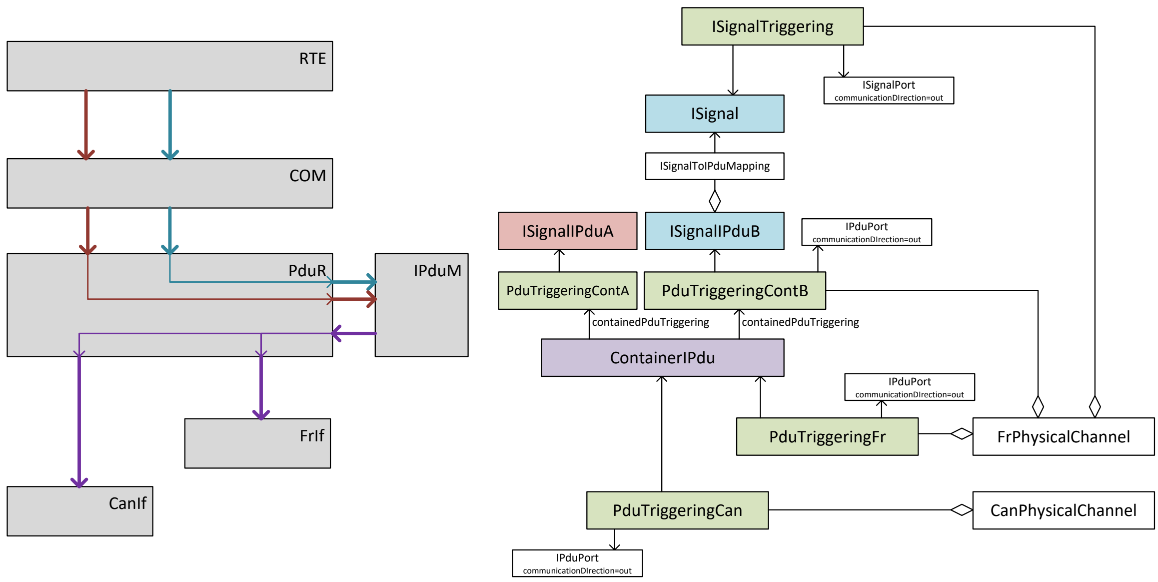

Figure 6.119: Pdu Router Container Pdu fan-out example

6.11.2.1.4 Pdu Router IPdu fan-out and SecOC / non SecOC

In the example figure 6.120 the PduR takes an ISignalIPdu from the Com module and performs a fan-out on that ISignalIPdu.

On one side the ISignalIPdu is handed over to the CanIf for direct transmission on the CanPhysicalChannel. The *PduTriggeringSec* is owned by the CanPhysicalChannel and has a corresponding *IPduPort* defined. Note that there is an alternative modeling approach discussed in section 6.1.1.

On the other side the ISignalIPdu is handed to the SecOC module. In the SecOC module a SecuredIPdu is created and handed back to the PduR. Then the PduR hands that SecuredIPdu to the FrIf for transmission on the FlexrayPhysicalChannel.

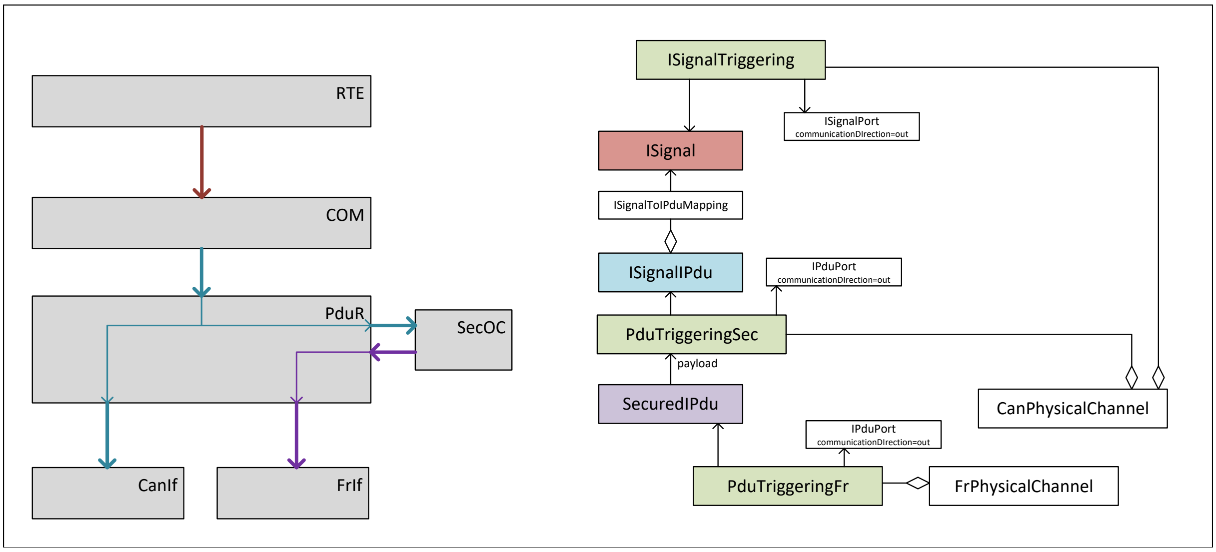

Figure 6.120: Pdu Router IPdu fan-out and SecOC / non SecOC example

6.11.2.2 Flexray Interface fan-out

The Flexray interface supports a fan-out where one Pdu is mapped into more than one frame on the same CommunicationCluster.

[TPS_SYST_01113] FlexRay Interface fan-out support ⌈The redundant transmission in the FlexRay Interface in the static segment is described by

- one FlexrayFrameTriggering on each PhysicalChannel
- both FlexrayFrameTriggerings refer to the same FlexrayFrame with the same Pdu
- each FlexrayFrameTriggering aggregates the same number of FlexrayAbsolutelyScheduledTimings
- for every FlexrayAbsolutelyScheduledTiming on one PhysicalChannel a corresponding FlexrayAbsolutelyScheduledTiming with identical values shall be defined on the other PhysicalChannel

⌋

If the fan-out is specified between different FlexRay channels of the same cluster it shall be handled by the FlexRay Interface.

The Flexray Interface does NOT handle fan-out/in between different clusters.

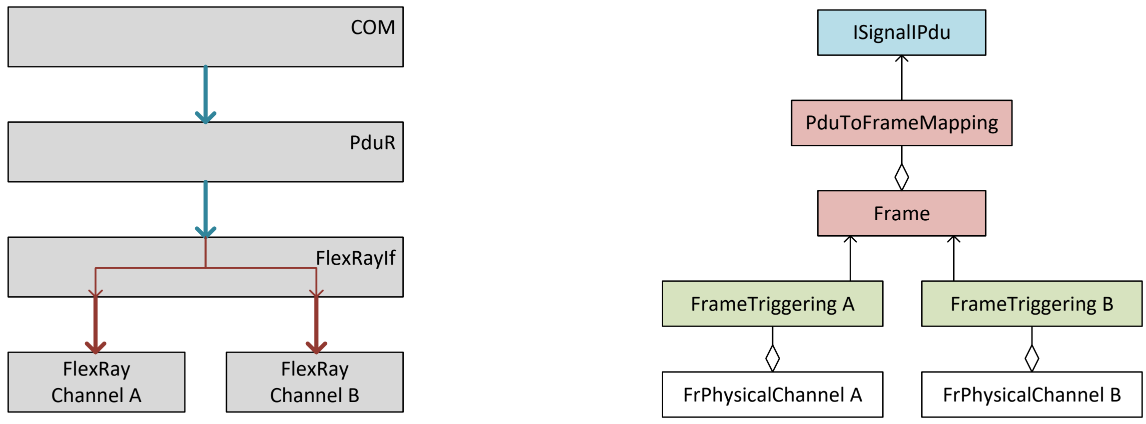

Figure 6.121: Bus Interface fan-out

6.11.2.3 Socket Adapter fan-out

The AUTOSAR Socket Adapter module [36] is capable to perform a PDU fan-out by itself.

In case of socket configuration for Service Discovery only the maximum number of socket connections is specified in the system description: AbstractServiceInstance refers to an ApplicationEndpoint with maxNumberOfConnections.

The example in figure 6.122 illustrates a ProvidedServiceInstance with a reference to an ApplicationEndpoint.maxNumberOfConnections set to 3. The Socket Adapter will be configured with 3 socket connections to be used for this ProvidedServiceInstance.

The payload used in this example is an ISignalIPdu which gets assigned a SOME/IP headerId via the aggregated SoConIPduIdentifier.

Depending on the actually subscribed clients the number of used socket connections will depend on the runtime situation.

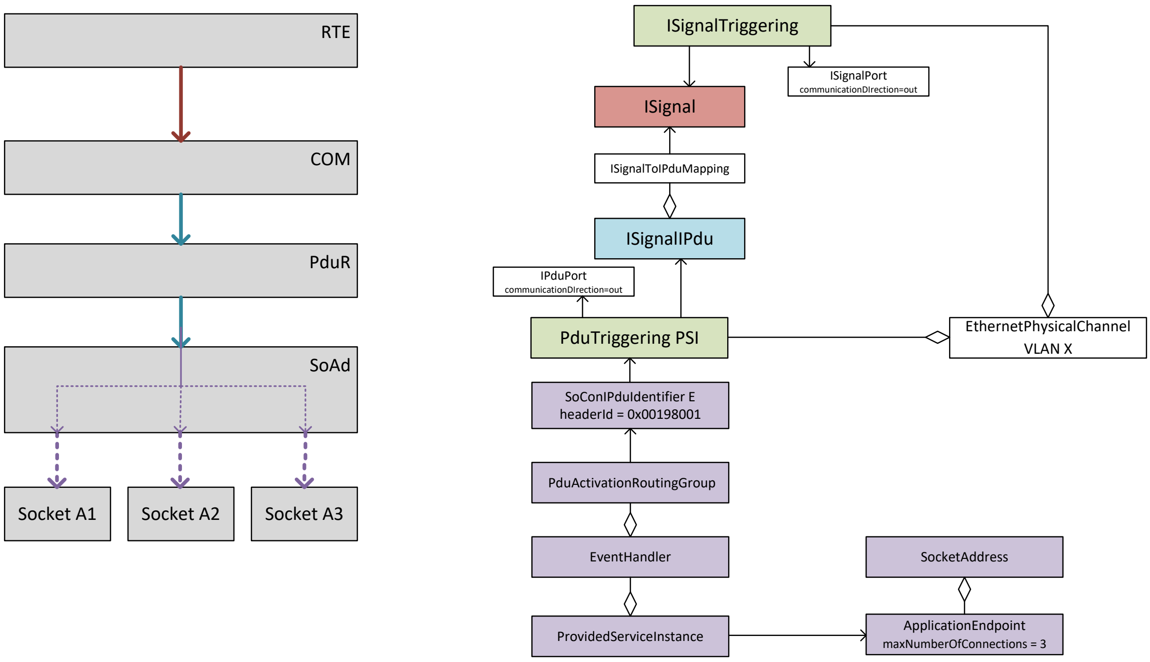

Figure 6.122: Socket Adapter fan-out with Service Discovery

In case of a static socket configuration the actual active number of possible Socket Adapter fan-out targets and their configuration is already known at configuration time. The example in figure 6.123 shows an `ISignalIPdu` which is fan-out to two statically configured VLANs.

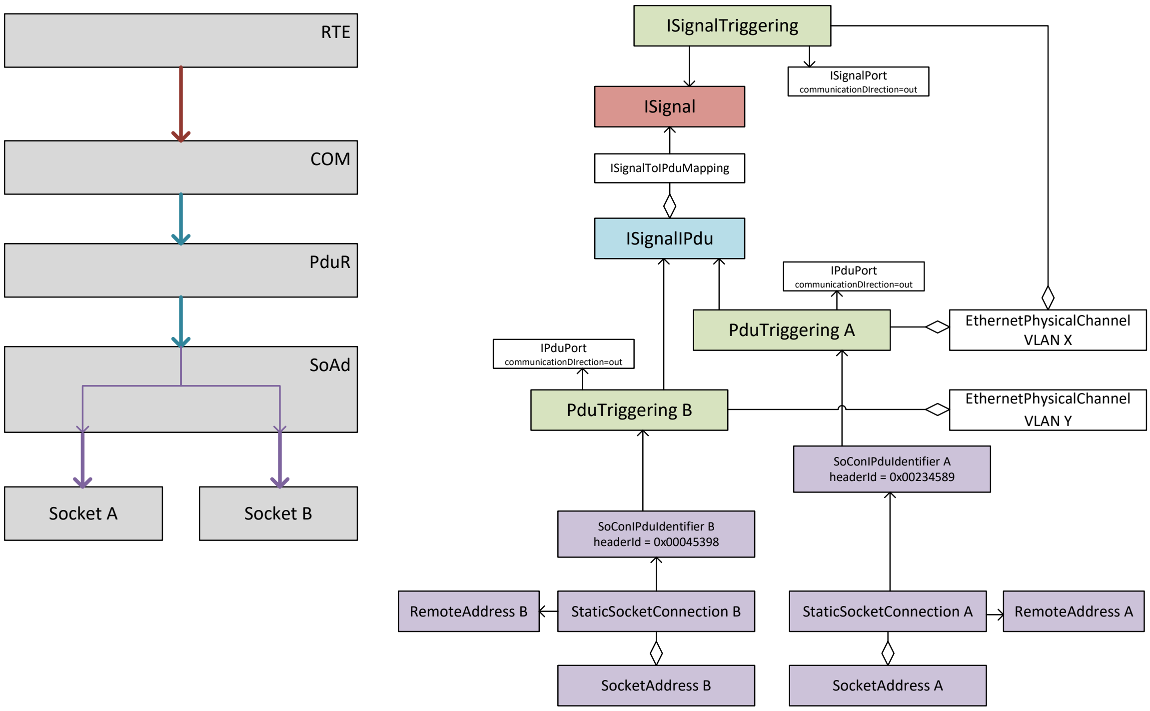

Figure 6.123: Static configured Socket Adapter fan-out to different VLANs

If the fan-out targets are located on the same VLAN several `StaticSocketConnections` can be defined referring to the same `SoConIPduIdentifier`. This is shown in figure 6.124.

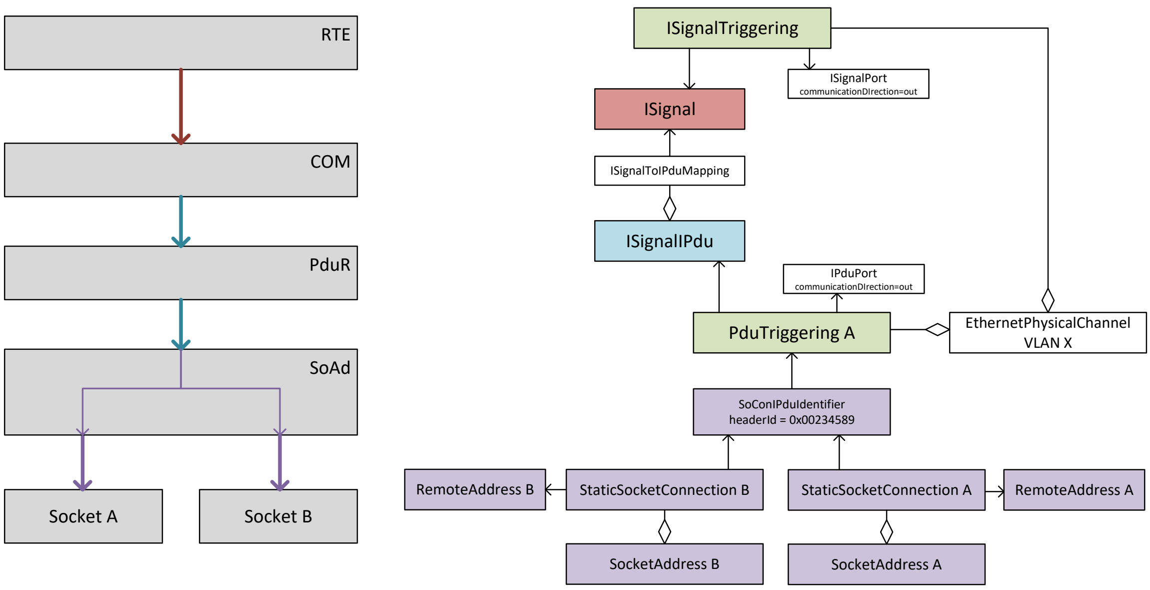

Figure 6.124: Static configured Socket Adapter fan-out to the same VLAN

6.11.3 Frame fan-out

[TPS_SYST_01114] Frame fan-out support ⌈AUTOSAR supports the Frame fan-out only on the FlexrayCluster (see [TPS_SYST_01113]).⌋

6.12 Fan-in

AUTOSAR supports the following fan-ins:

- RTE Signal fan-in
- Pdu fan-in
- IPdu Container fan-in

Note that the specification in this section does not apply for Client/Server communication. The respective details are described in section 5.2.1.3.

6.12.1 RTE fan-in

The RTE supports a "signal fan-in" where two or more ISignals of the same SystemSignal are received in multiple ISignalIPdus from potentially multiple senders, as described in [SWS_Rte_03760] and [SWS_Rte_03761].

[TPS_SYST_02357] RTE fan-in support for a SystemSignal ⌈RTE fan-in from multiple ISignals to a single SystemSignal is enabled in a System Description if the following conditions apply:

- several ISignals reference the SystemSignal in the role systemSignal and
- the SystemSignal is not referenced by a SystemSignalGroup
- a DataMapping references the SystemSignal and
- the DataMapping references an element in a RPortPrototype and
- the ISignals are received by the EcuInstance on which the RTE is running, i.e. an ISignalTriggering exists that references the ISignal in the role iSignal and references a ISignalPort of the EcuInstance with communicationDirection in.

⌋

Figure 6.110 shows a scenario where the RTE does not need to perform a fan-in since each SystemSignal is referenced by exactly one ISignal.

Please note that in all example scenarios that are shown in this chapter the ISignal-ToIPduMappings shall be modeled for each ISignal or ISignalGroup. For simplicity reasons, the following diagrams leave the ISignalToIPduMappings out and just assume that they exist.

In addition for simplicity reasons the examples scenarios are showing always one OUT EcuPort and/or one IN EcuPort. But the different ISignalTriggerings are also allowed to reference own ISignalPorts that are defined on the EcuInstance.

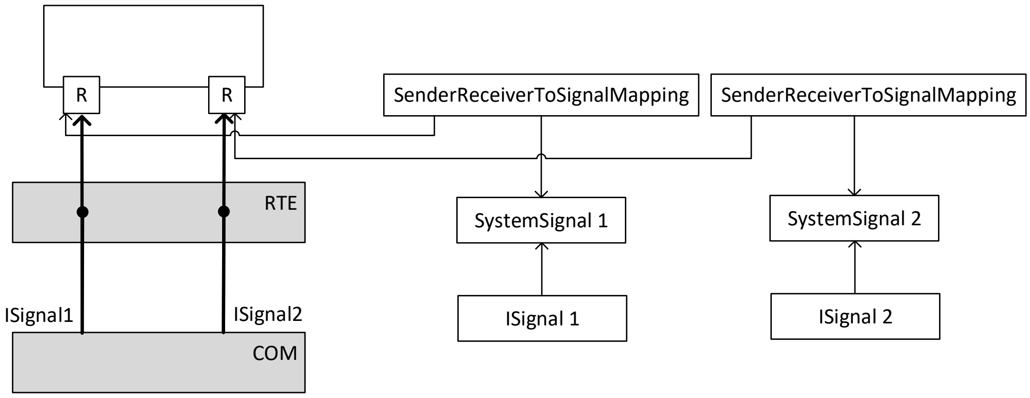

Figure 6.125: Scenario where RTE does not perform a fan-in

Figure 6.126 shows a scenario where the RTE needs to perform a fan-in since the SystemSignal is referenced by two ISignals, a SenderReceiverToSignalMapping is defined that maps a VariableDataPrototype in a SenderReceiverInterface of a RPortPrototype to the SystemSignal and the ISignals are both received by the EcuInstance.

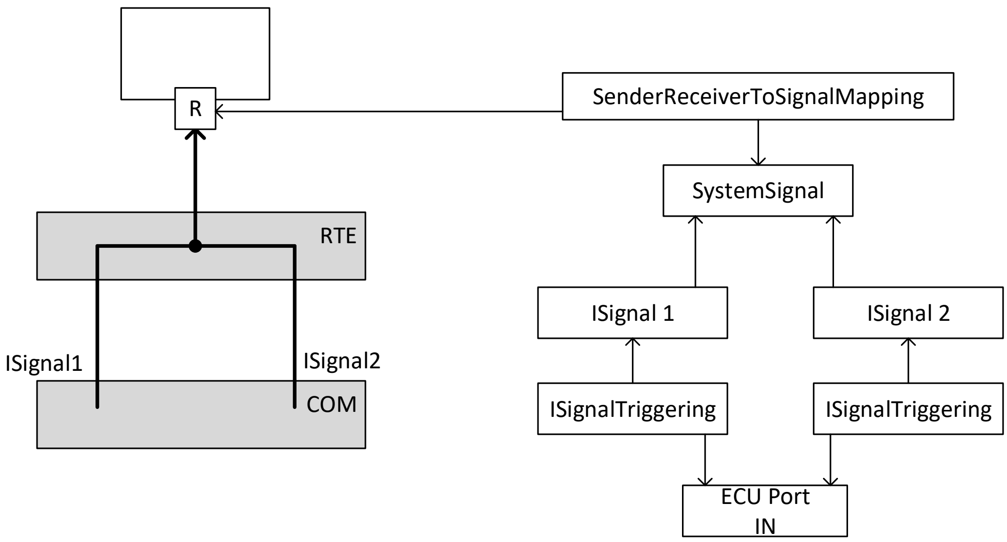

Figure 6.126: Scenario where RTE does perform a fan-in

A fan-in of two ISignalGroups can be modeled as well. In that case, two or more ISignalGroups refer to the same SystemSignalGroup, and each of the contained ISignals of the ISignalGroup needs to refer to its corresponding SystemSignal which in turn is part of the SystemSignalGroup.

[TPS_SYST_02358] RTE fan-in support for a SystemSignalGroup ⌈RTE fan-in from multiple ISignalGroups to a single SystemSignalGroup is enabled in a System Description if the following conditions apply:

- several ISignalGroups reference the SystemSignalGroup in the role systemSignalGroup and
- a DataMapping references the SystemSignalGroup and
- the DataMapping references an element in a RPortPrototype and
- each of the contained ISignals of the ISignalGroup refers to its corresponding SystemSignal which in turn is part of the SystemSignalGroup and
- the ISignalGroups are received by the EcuInstance on which the RTE is running, i.e. an ISignalTriggering exists that references the ISignalGroup in the role iSignalGroup and references a ISignalPort of the EcuInstance with communicationDirection in.

⌋

Figure 6.127 shows a scenario where the RTE needs to perform a fan-in since the SystemSignalGroup is referenced by two ISignalGroups, a SenderReceiverToSignalGroupMapping is defined that maps a VariableDataPrototype in a SenderReceiverInterface of a RPortPrototype to the SystemSignalGroup and both ISignalGroups are transmitted by the EcuInstance.

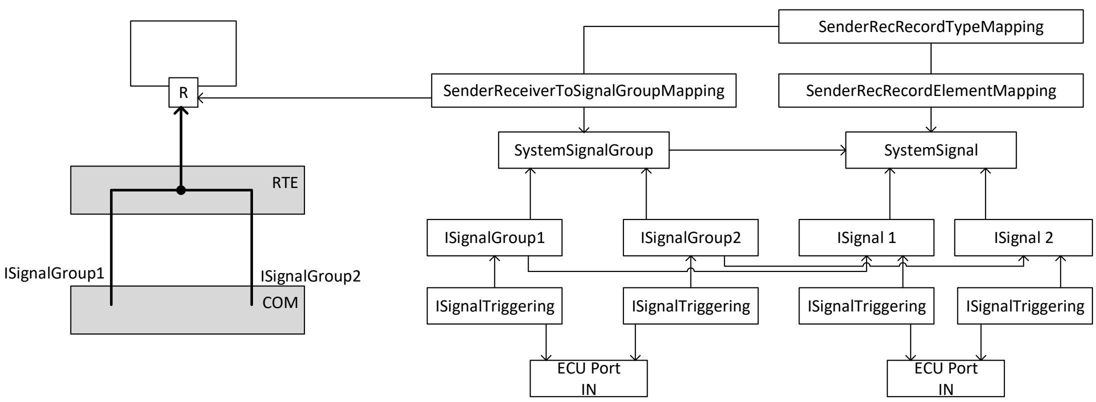

Figure 6.127: Scenario where RTE does perform a fan-in for a SystemSignalGroup

[TPS_SYST_03079] No RTE fan-in support for stand-alone SystemSignal and the same SystemSignal as part of a SystemSignalGroup ⌈There is no support by the RTE for a setup where a SystemSignal is received both, via a stand-alone ISignal as well as part of an ISignalGroup, if the DataMapping references the SystemSignalGroup.⌋

[TPS_SYST_03079] implies that [TPS_SYST_03078] does not apply for SystemSignalGroup reception. The rational for this restriction is that the DataMapping references the SystemSignalGroup, and thus the application software component expects a composed data element. But in the case of the single SystemSignal reception only one member of that composed data element would be available for update. This setup is excluded.

6.12.2 Pdu fan-in

The Pdu Router supports the “PDU fan-in” where one IPdu is received from several sources.

[TPS_SYST_02376] Pdu Router fan-in support ⌈The Pdu Router fan-in is described by several PduTriggering elements that are referencing the same Pdu and each of these PduTriggerings is referencing an IPduPort with communicationDirection set to in of the same EcuInstance. According to the Cluster/Channel aggregation, the Pdu Router determines the clusters to use in its routing.⌋

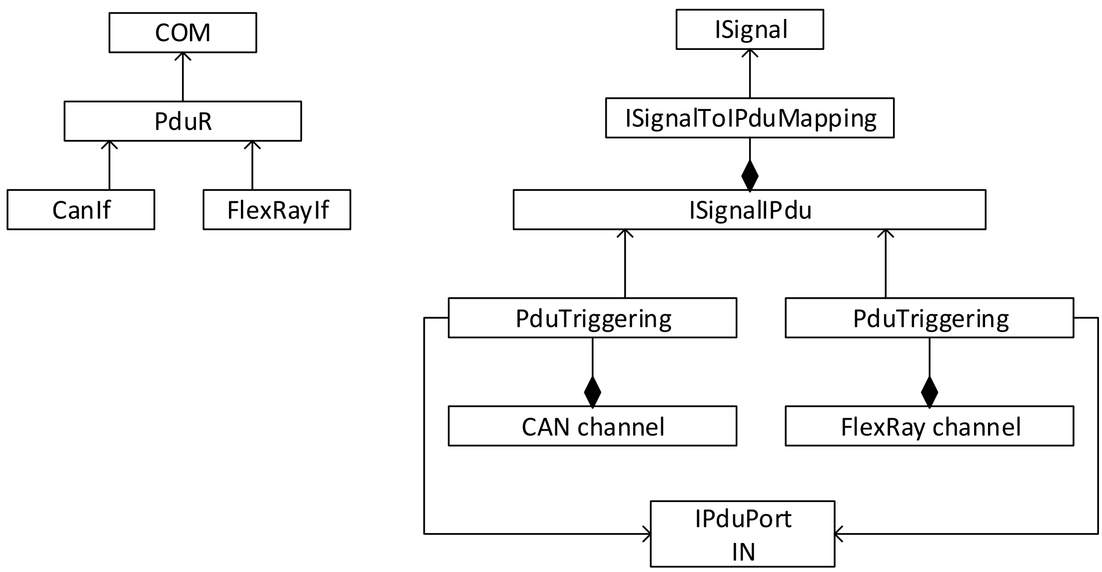

Figure 6.128: Scenario where PduR does perform a fan-in

6.12.3 IPdu Container fan-in

Using the ContainerIPdu (see section 6.3.1) it is possible to transport several Contained IPdus in one ContainerIPdu.

It is also possible to accept a Contained IPdu from any ContainerIPdu with ContainerIPdu.rxAcceptContainedIPdu set to RxAcceptContainedIPduEnum.acceptAll.

The example in figure 6.129 illustrates a scenario where in the configuration the ContainedIPdu is explicitly defined to be part of the two ContainerIPdus CIPdu1 and CIpdu3. Both ContainerIPdus have rxAcceptContainedIPdu set to acceptAll.

But also ContainerIPdu CIPdu2 has rxAcceptContainedIPdu set to acceptAll. And there is no explicit placement of ContainedIPdu in CIPdu2.

Due to the nature of acceptAll, if ContainedIPdu is received in CIPdu2 it will also be forwarded to the Pdu Router.

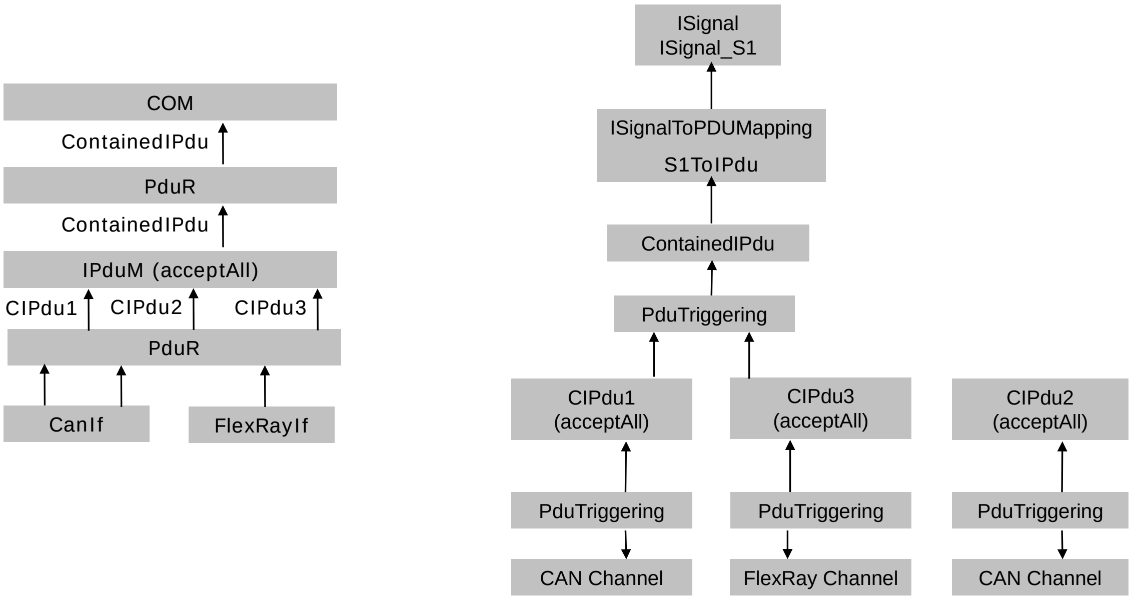

Figure 6.129: Container acceptAll fan-in

6.13 Log and Trace

The Dlt module collects debug information from applications or other software modules, adds metadata to the debug information, and sends the information to a Dlt sink.

The DltConfig element defines a Dlt module configuration for a specific EcuInstance and uses elements from the Log And Trace Extract Template to describe the source of log and trace messages (application or module that produces the logging information) and the DltMessage that is sent out from the source to a sink.

[TPS_SYST_02373] Assignment of a Dlt Ecu Identifier to an EcuInstance ⌈The EcuInstance is represented in the Log And Trace Extract by the DltEcu that is referenced from the EcuInstance via the aggregated DltConfig in the role dltEcu. The referenced DltEcu defines the ecuId that is transported in the standard header of the log and trace message.⌋

The DltApplication in the DltEcu is connected to a DltContext that is used to group DltMessages that are generated by the DltApplication. The PhysicalChannel on which the DltMessage is transported is represented by the DltLogChannel.

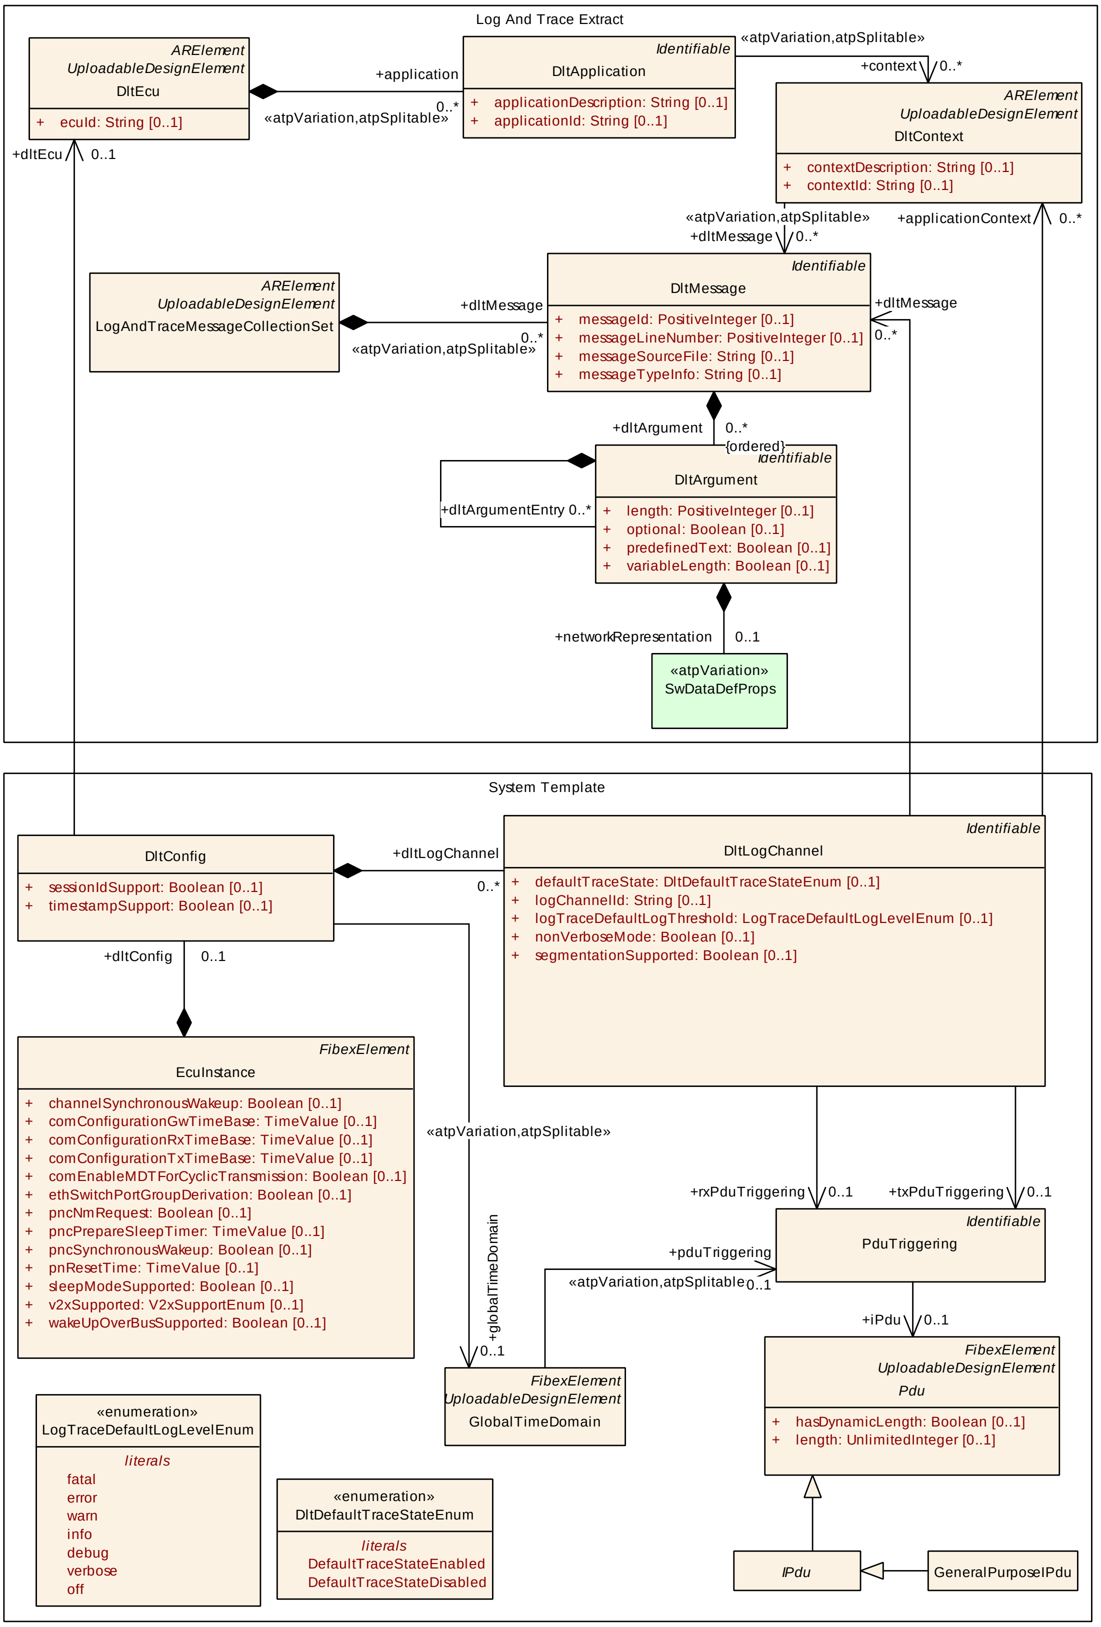

Figure 6.130: Dlt configuration of DltLogChannels and DltMessages

[TPS_SYST_02264] Usage of `DltLogChannel` ⌈In each `DltConfig` the `physicalChannels` that are used to transport the `DltMessages` are configured by the `DltLogChannel` elements.

Each `DltLogChannel` points to one `PduTriggering` in the role `txPduTriggering` to describe the Dlt Pdu that is transmitted by the `DltLogChannel`. The `rxPduTriggering` role is used to describe the Dlt Pdu that is received by the `DltLogChannel`.⌋

[TPS_SYST_02374] Assignment of `DltMessage` to `DltLogChannels` ⌈The assignment of `DltMessages` to a `DltLogChannel` for log/trace output is created with the `dltMessage` reference.⌋

[TPS_SYST_02375] Definition of `DltLogChannels` source ⌈The `DltLogChannel` references the `DltContext` in the role `applicationContext` to define the `contextId` and `applicationId` of the Software Component or Basic Software Module that produces the `DltMessage` for transmission to the sink.⌋

6.14 Support of Complex Drivers

The System Template allows the integration of custom communication means into AUTOSAR EcuInstances.

[TPS_SYST_01115] CDD communication support

Upstream requirements: RS_SYST_00043

⌈The elements UserDefinedPdu and UserDefinedIPdu shall be used to describe the Pdu-based communication via Complex Drivers.⌋

The UserDefinedPdu and UserDefinedIPdu elements are described in chapter 6.3 in more detail.

The UserDefinedIPdu can be used to describe the communication if a new BSW module was added above the PduR, e.g a Diagnostic Service.

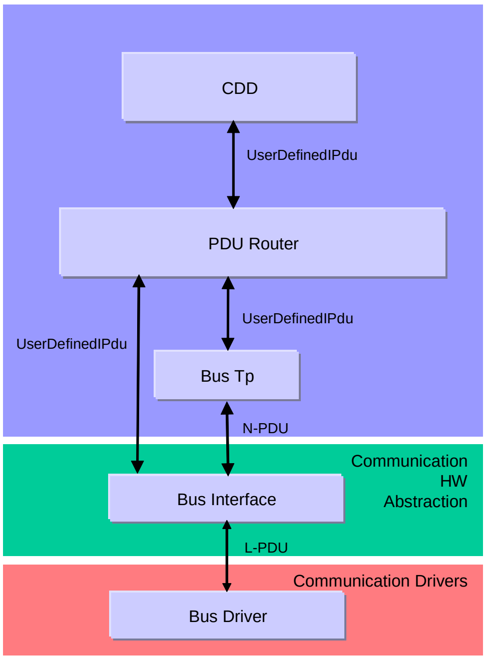

Figure 6.131: CDD over PduR

The UserDefinedPdu can be used to describe the communication if a new BSW module was added above an Interface, e.g. a new Nm module or XCP.

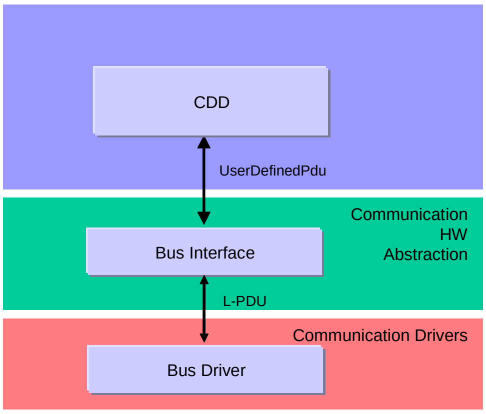

Figure 6.132: CDD over Bus Interface

6.15 MetaData in SenderReceiverInterface

As described in [4], there is the ability for the application software to unlock access to Pdu meta-data by using the aggregation SenderReceiverInterface.metaDataItemSet.

This modeling allows for the arbitrary definition of meta-data semantics that - of course - has to be supported by the Pdu where a specific dataElement is finally mapped to.

This consistency is ensured by deriving the Pdu meta-data from the modeling in SenderReceiverInterfaces. However, this approach can only work if all dataElements mapped to the given Pdu define the same meta-data structure or do not define the usage of meta-data at all.

[constr_5100] Compatibility of two MetaDataItemSets

Imposition time: IT_SysDesc

⌈Under the condition that sender and receiver typed by a SenderReceiverInterface use meta-data and are mapped to the same EcuInstance the following condition applies: two MetaDataItemSets are compatible if all of the following conditions are fulfilled:

- They aggregate the same number of MetaDataItems.
- The value of MetaDataItem.length of corresponding MetaDataItems is identical.
- The value of MetaDataItem.metaDataItemType of corresponding MetaDataItems is identical.

⌋

[constr_5101] Consistent Definition of meta-data

Imposition time: IT_SysDesc

⌈If the dataElement referenced by a SenderReceiverToSignalMapping is also referenced by a MetaDataItemSet in the role dataElement and the mapping via SystemSignal, ISignal, and ISignalToIPduMapping down to an ISignalIPdu exists then all other dataElements that are also mapped to the same ISignalIPdu shall either

- not be referenced by a MetaDataItemSet in the role dataElement (i.e. does not make use of meta-data) or
- the definition of meta-data in the context of the affected SenderReceiverInterfaces is compatible (according to the definition of compatible specification of meta-data described in [constr_5100]).

⌋

6.16 Signal Service Translation

AUTOSAR Adaptive Platform restricts communication paradigm to Service-oriented communication. A major part of the vehicle however still uses Signal-based communication means, therefore a translation of these two approaches has to be performed.

One major goal of AUTOSAR is that it covers both

- high-performance microprocessor Machines (connected via high payload and high bandwidth Ethernet networks)
- highly embedded microcontroller ECUs (connected via ethernet, but also via low payload and low bandwidth CAN and LIN networks).

A seamless development of a vehicle shall be supported with one AUTOSAR methodology. Therefore a translation is required which closes the gap between

- Signal-based communication on Classic platform
- Service-oriented communication on Adaptive platform.

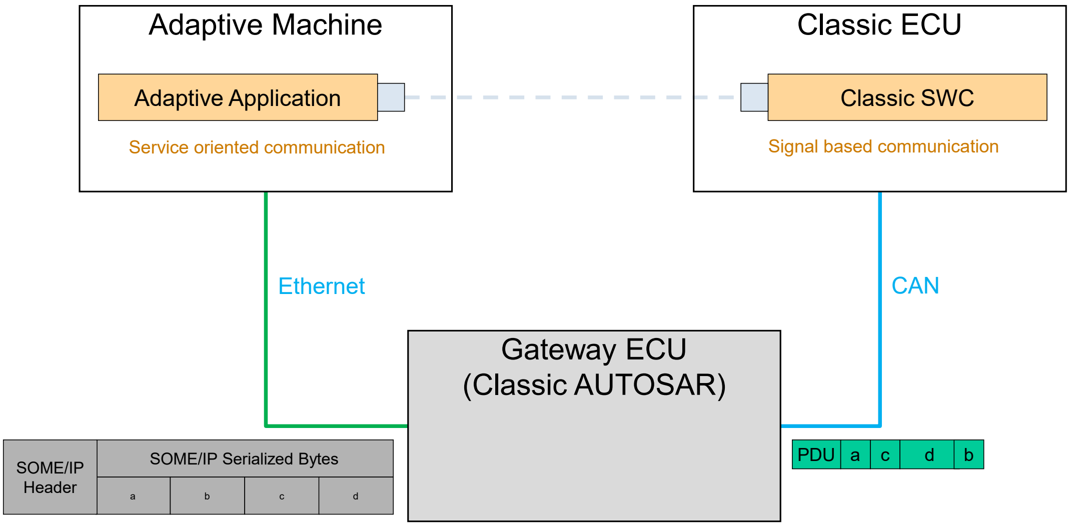

Figure 6.133: `Signal/Service Translation` in Classic platform gateway ECU

The goal of this chapter is to standardize a translation between the two communication transport configurations on an AUTOSAR Classic platform ECU. A similar approach is also provided in the Manifest specification for the Adaptive platform [32]. It is up to the vehicle architecture design to choose whether the `signal/service translation` shall be implemented on a Classic platform ECU or on an Adaptive platform Machine.

6.16.1 Architectural setup

The implementation of the `signal/service translation` on the Classic platform is done in an Application Software Component above the RTE. This applies for *events* and *field notifiers*. Methods are handled separately (see section 6.16.1.1).

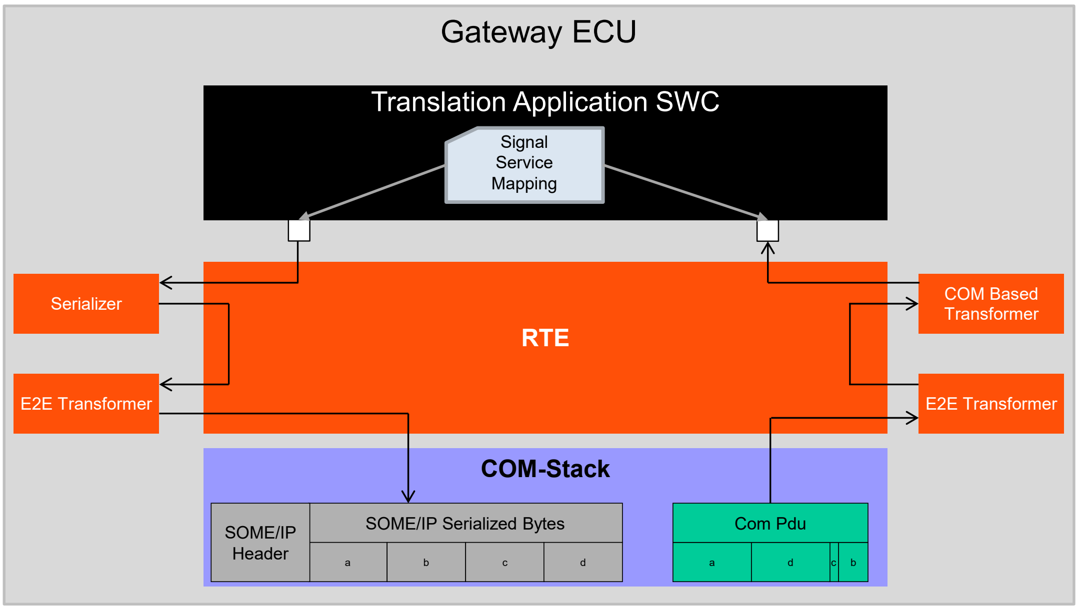

Figure 6.134: Signal/Service Translation Application Software Component

For the signal-based part the full functionality of the Classic platform COM-Stack is available and may be configured such that the signal-based ISignalIPdus may originate from a variety of sources (Can, Lin, FlexRay) and the ISignalIPdus may be safety and security protected.

For the service-oriented part it has to be guaranteed that the defined SOME/IP Service actually is compatible to the Adaptive platform. This applies for the payload part (e.g. the SOME/IP serializer has to be used) as well as for the control path using *BswM* and *ServiceDiscovery*.

The behavioral part of the Translation Software Component itself defines how the data from signal-based side is transported to the service-oriented side, and vice versa (see section 6.16.4).

The following terminology is used in the context of signal/service translation:

Signal/service translation defines the feature this chapter is concerned with. It does not prescribe a specific translation direction.

Signal-service-translation defines the translation direction from a signal-based to a service oriented representation.

Service-signal-translation defines the translation direction from a service oriented to a signal-based representation.

6.16.1.1 Method handling

The handling of methods (or getter/setter calls of fields) has to be serialized using the SOME/IP transformer. And this is only supported on Ethernet networks (see [constr_5117]).

Therefore there is no need to perform a translation because the methods are already usable on the adaptive platform.

6.16.2 Mapping description

Signal/service translation is used to alter the serialization representation of data to be compatible with the respective transport network. I.e. on an Ethernet network a SOME/IP serialized data representation is mostly suitable, while on a CAN network the packed signal-based data representation often required due to the low payload data size available.

As indicated in section 6.16.1 the implementation of the translation shall be done in an Application Software Component above the RTE. For the definition of the intended mapping and behavior however the CompositionSwComponentType is used. This allows to represent the requirements on the translation and still allow some freedom with respect to the actual implementation later on.

The element which defines the behavioral aspects of the signal/service translation is the meta-class SignalServiceTranslationProps. The references to the VariableDataPrototype in the role translationTarget define to which events the SignalServiceTranslationProps apply. For this reference a VariableDataPrototypeInSystemInstanceRef is used (see also chapter B.8).

- In case of signal-service-translation the SignalServiceTranslationProps.translationTarget collect all resulting events which belong to one provided service instance.
- In case of service-signal-translation the SignalServiceTranslationProps.translationTarget collect all resulting signals which are translated from one service instance.

Table 6.343: SignalServiceTranslationEventProps

A simple `signal/service translation` setup is to have a one-to-one correspondence between the signal-based data definition and the service-oriented data definition. This is illustrated in figure 6.136.

Here the setup allows for a simple `PassThroughSwConnector` because the involved `PortInterface`s are identical.

Please consult with [constr_1248] in the Software Component Template [4] for details on the compatibility of connected `PortInterface`s.

Note that the translated *P1.dataX* and *P2.dataB* may be configured in the COM-Stack to be events that belong to one service instance or to belong to two different service instances. The setup in the example of figure 6.136 uses two `SignalServiceTranslationProps` elements and those use `SignalServiceTranslationEventProps`, indicating that *P1.dataX* belongs to a different service instance than *P2.dataB*.

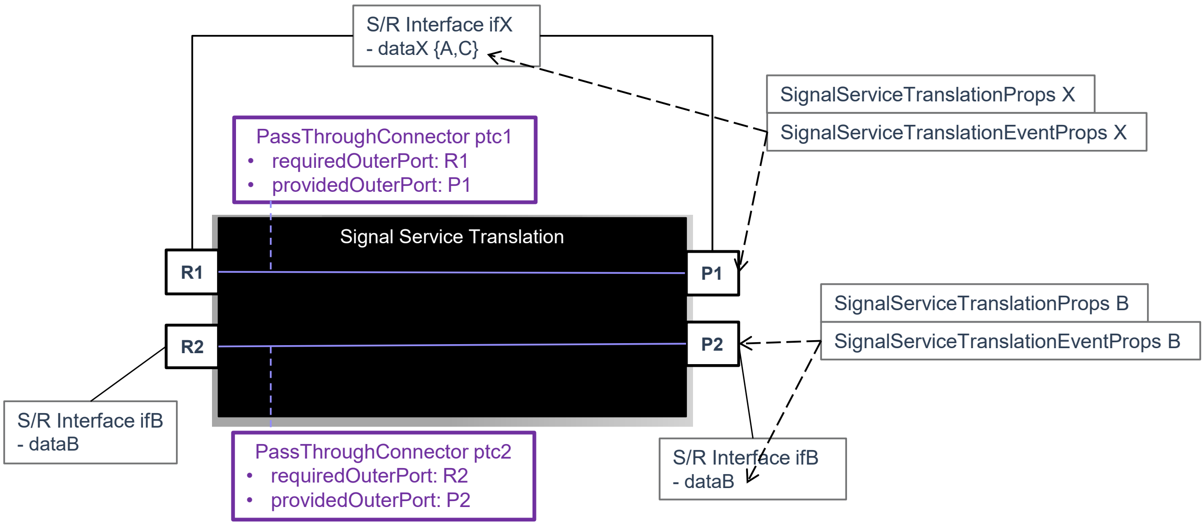

Figure 6.136: Mapping description using only PassThroughSwConnectors

The usage of the PassThroughSwConnector and (optionally) the accompanying PortInterfaceMapping already suffice to describe the intended mapping from a structural point of view:

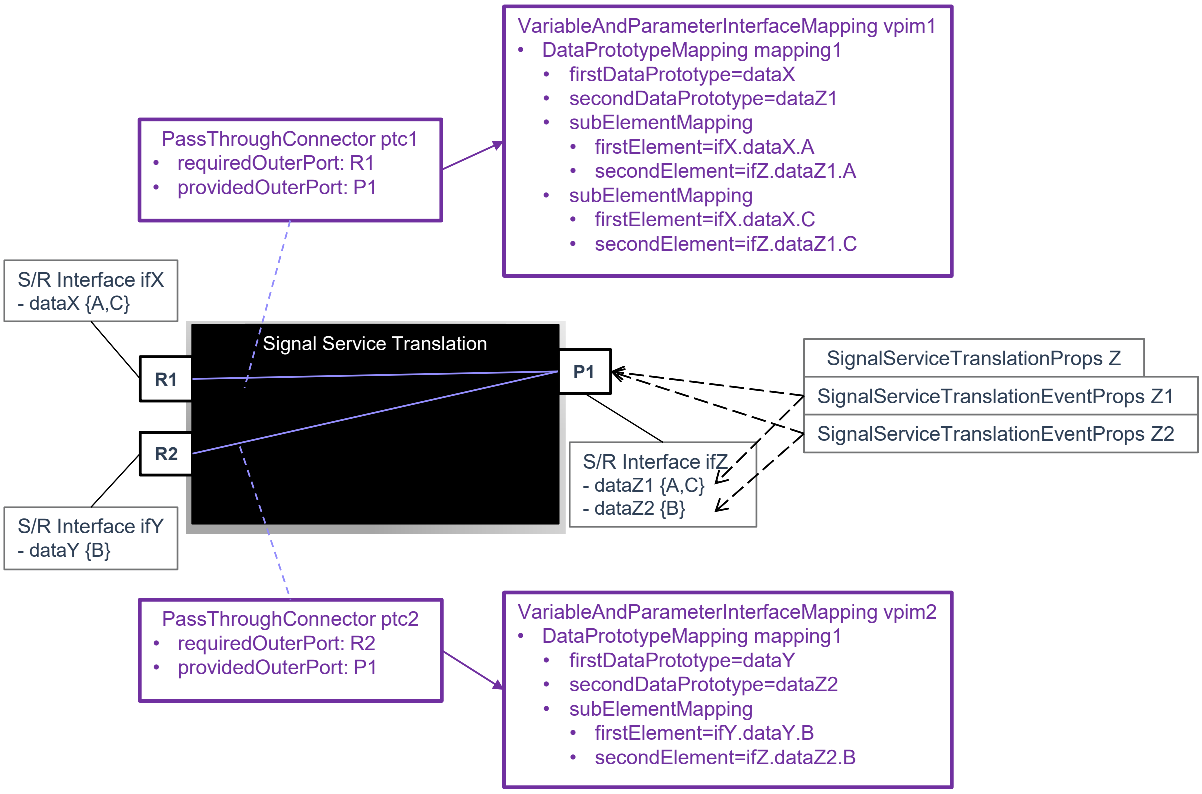

Figure 6.137: Mapping description using PassThroughSwConnectors and PortInterfaceMappings

In figure 6.137 the additional usage of PortInterfaceMappings is required because the connected PortInterfaces are not identical (in this example have different shortNames).

In this example there is only one SignalServiceTranslationProps element defined which uses two SignalServiceTranslationEventProps to refer to both the data elements *dataZ1* and *dataZ2*. Thus the translated events belong to the same service instance.

Although the figure 6.137 indicates that the output Port *P1* data *dataZ1* and *dataZ2* are composed of input from several sources, this is not true for the individual data elements. *P1.dataZ1* is solely composed out of *R1.dataX*, while *P1.dataZ2* is composed out of *R2.dataY*. Thus the example shown is still a mapping from *one source*.

The usage of PortInterfaceMapping (specifically VariableAndParameterInterfaceMapping with a DataPrototypeMapping) brings along a restriction on the applicability of the PassThroughSwConnector usage. Specifically the mapped elements have to be *both* either

- typed by an ApplicationPrimitiveDataType or
- typed by an ApplicationCompositeDataType.

The mixed case (where one AutosarDataPrototype is typed by an ApplicationPrimitiveDataType and the other is typed by an ApplicationCompositeDataType) is not supported by the DataPrototypeMapping. This is illustrated in figure 6.138: The interface *ifX* has two VariableDataPrototypes typed by ApplicationPrimitiveDataTypes, while the *ifZ* has a VariableDataPrototype typed by a ApplicationCompositeDataType (having the members *A, C*).

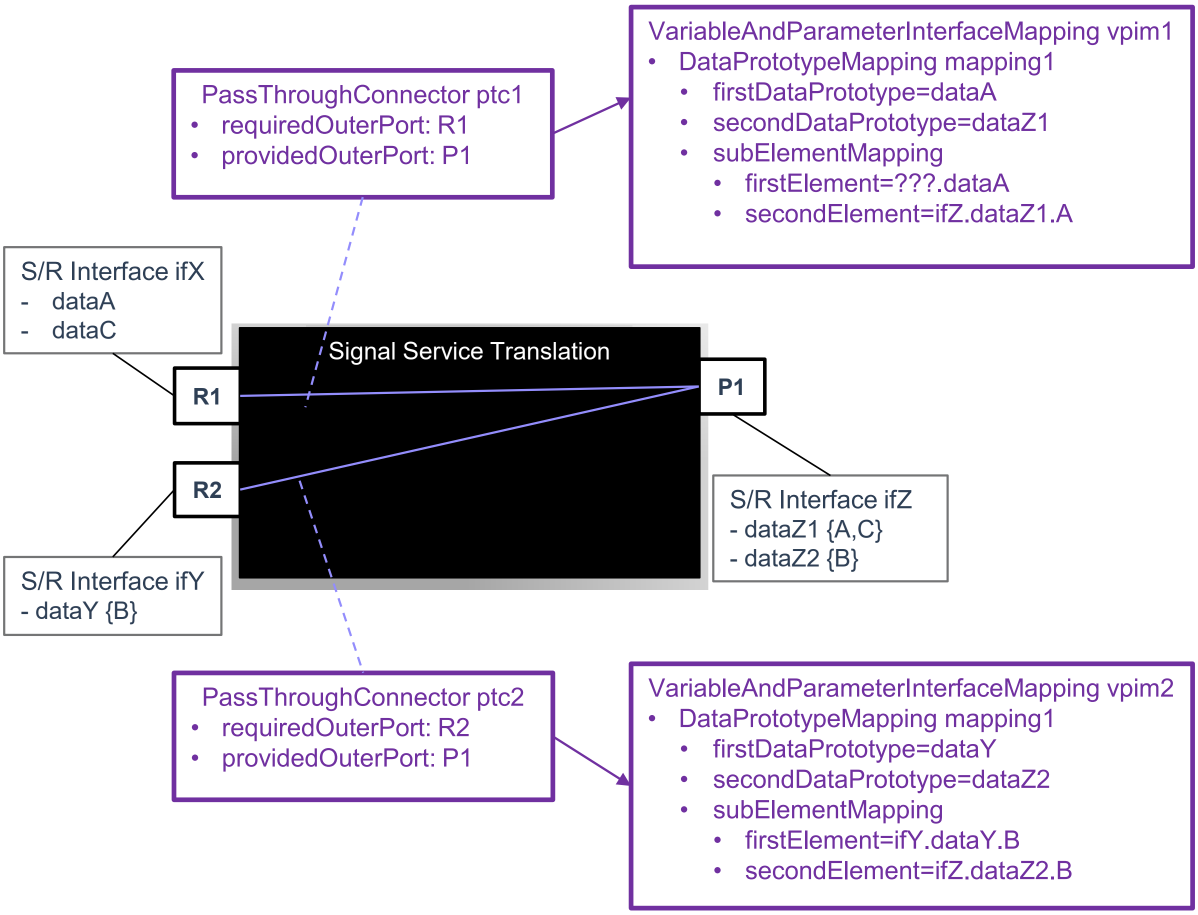

Figure 6.138: Not supported mapping description using PassThroughSwConnectors and PortInterfaceMappings

6.16.2.1 Filters and Transmission Triggers

The `filter`s and `transmissionTrigger`s can be used to define behavioral aspects of the `signal/service translation`. They are defined in the `SignalServiceTranslationElementProps`, which is aggregated by the `SignalServiceTranslationEventProps`.

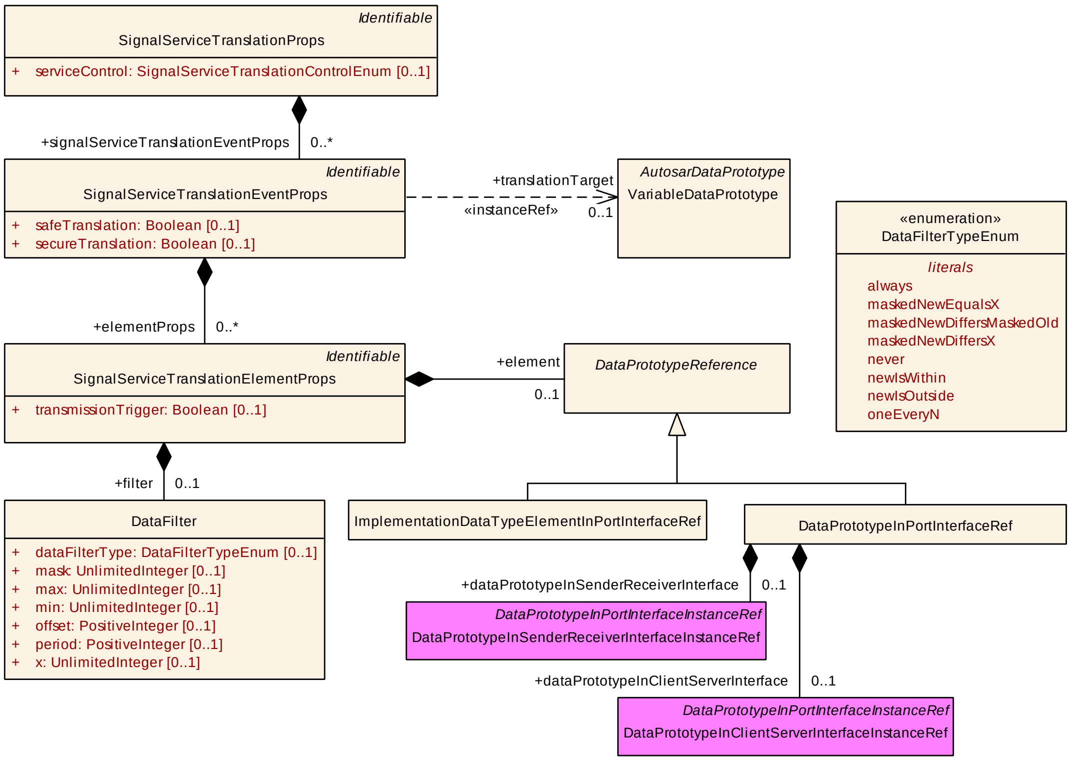

Figure 6.139: `Signal/Service Translation` element properties

Class	**SignalServiceTranslationElementProps**			
Package	M2::AUTOSARTemplates::CommonStructure::SignalServiceTranslation			
Note	Defined translation properties for individual mapped elements.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	SignalServiceTranslationEventProps.elementProps			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
element	DataPrototype Reference	0..1	aggr	Reference to the leaf element the SignalService TranslationElementProps apply to.
filter	DataFilter	0..1	aggr	Defines an optional filter to be applied during translation.
transmission Trigger	Boolean	0..1	attr	Defines whether the source element (which is mapped to the referenced element) triggers the sending of the respective payload.

Table 6.344: SignalServiceTranslationElementProps

To which data the `filter` and/or `transmissionTrigger` applies is defined by the combination of `SignalServiceTranslationEventProps.translationTarget` and `SignalServiceTranslationElementProps.element` references.

In case the `filter` and/or `transmissionTrigger` shall apply to the `translationTarget` as a whole the reference `SignalServiceTranslationElementProps.element` shall not be defined. This is specifically true if `SignalServiceTranslationEventProps.translationTarget` refers to a `VariableDataPrototype` that is typed by a primitive `AutosarDataType`:

[constr_3651] No element in case translationTarget is primitive

Imposition time: IT_SysDesc

⌈If SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by a primitive AutosarDataType then the reference SignalServiceTranslationElementProps.element shall not be defined.⌋

Since the reference DataPrototypeReference is used in several scenarios (see [TPS_SYST_02195]) it needs to be constrained for the usage in scope of the signal/service translation (i.e., for SignalServiceTranslationElementProps.element): The DataPrototypeReference used to define the SignalServiceTranslationElementProps.element is restricted to either DataPrototypeInSenderReceiverInterfaceInstanceRef or ImplementationDataTypeElementInPortInterfaceRef.

[constr_3652] Allowed sub-classes of DataPrototypeReference in the context of signal/service translation

Imposition time: IT_SysDesc

⌈If a DataPrototypeReference in the role SignalServiceTranslationElementProps.element is used then following sub-classes are supported:

- if the reference target is typed by an ApplicationDataType then the DataPrototypeInSenderReceiverInterfaceInstanceRef shall be used and shall target an ApplicationCompositeElementDataPrototype.
- if the reference target is typed by an ImplementationDataType then the ImplementationDataTypeElementInPortInterfaceRef shall be used.

⌋

It is important that the SignalServiceTranslationEventProps.translationTarget reference and the SignalServiceTranslationElementProps.element in the context of one SignalServiceTranslationEventProps are consistent.

Consistent usage of either ApplicationDataType or ImplementationDataType and consistent translationTarget target and element root:

[constr_3653] Consistent translationTarget and element in case ApplicationDataType is used

Imposition time: IT_SysDesc

⌈If the SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by an ApplicationDataType (targetDataPrototype of the VariableDataPrototypeInSystemInstanceRef) then every SignalServiceTranslationElementProps.element reference that is defined in the context of the SignalServiceTranslationEventProps shall have that

VariableDataPrototype as the rootDataPrototypeInSr of the DataPrototypeInSenderReceiverInterfaceInstanceRef.⌋

[constr_3654] Consistent translationTarget and element in case ImplementationDataType is used

Imposition time: IT_SysDesc

⌈If the SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by an ImplementationDataType (targetDataPrototype of the VariableDataPrototypeInSystemInstanceRef) then every SignalServiceTranslationElementProps.element reference that is defined in the context of the SignalServiceTranslationEventProps shall have that VariableDataPrototype as the rootDataPrototype of the ImplementationDataTypeElementInPortInterfaceRef.⌋

[TPS_SYST_03062] Definition of a primitive target for SignalServiceTranslationElementProps

Upstream requirements: RS_SYST_00059

⌈The target of a SignalServiceTranslationElementProps is considered primitive if either:

- SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by a primitive AutosarDataType or
- SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by a composite AutosarDataType and SignalServiceTranslationElementProps.element refers to an AutosarDataPrototype that is typed by a primitive AutosarDataType.

⌋

[TPS_SYST_03063] Definition of a composite target for SignalServiceTranslationElementProps

Upstream requirements: RS_SYST_00059

⌈The target of a SignalServiceTranslationElementProps is considered composite if either:

- SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by a composite AutosarDataType and no reference for SignalServiceTranslationElementProps.element is given or
- SignalServiceTranslationEventProps.translationTarget refers to a VariableDataPrototype that is typed by a composite AutosarDataType and SignalServiceTranslationElementProps.element refers to an AutosarDataPrototype that is typed by a composite AutosarDataType.

⌋

The filter can be used to define a guard on the translated data. If the input data does no pass the filter then the impacted data is not translated. It depends on the kind of the translated data and the filter intention which filter types are supported:

[constr_3655] Supported filter types for primitive SignalServiceTranslationElementProps

Imposition time: IT_SysDesc

⌈If the target for SignalServiceTranslationElementProps is defined as primitive according to [TPS_SYST_03062] then the following values for dataFilterType are supported:

- always
- maskedNewDiffersMaskedOld
- maskedNewDiffersX
- maskedNewEqualsX
- never
- newIsOutside
- newIsWithin
- oneEveryN.

⌋

[constr_3656] Supported filter types for composite SignalServiceTranslationElementProps

Imposition time: IT_SysDesc

⌈If the target for SignalServiceTranslationElementProps is defined as composite according to [TPS_SYST_03062] then the following values for dataFilterType are supported:

- always
- never
- oneEveryN.

⌋

The SignalServiceTranslationElementProps.transmissionTrigger defines whether translated data actually triggers the sending of the SignalServiceTranslationEventProps.translationTarget.

One aspect is when the translationTarget is composed out of several sources (see [TPS_SYST_03040]). In this section the discussion is about whether transmissionTrigger is also applicable for the case where the translationTarget is created out of one source.

If the Translation Application Software Component is implemented to perform the signal/service translation in a periodic way (see [TPS_SYST_03042] and [TPS_SYST_03043]) the transmissionTrigger can be used to define whether the signal/service translation of that specific data actually triggers the sending or whether the sending is deferred to the periodic invocation of the Translation Application Software Component.

If the signal/service translation is configured to be done in a periodic way, then

- if the transmissionTrigger is set to *true* at least once then the translationTarget will be produced based on the periodicity AND additionally every time the input data arrives where transmissionTrigger is set to *true*
- if the transmissionTrigger is set to *false* for all members of the translationTarget then the translationTarget will be produced based on the periodicity ONLY.

If the signal/service translation is configured to be done in a NON periodic way (event driven only), then

- if the transmissionTrigger is set to *true* at least once then the translationTarget will be produced every time the input data arrives where transmissionTrigger is set to *true*
- if the transmissionTrigger is set to *false* for all members of the translationTarget then the translationTarget will NOT be sent at all (as there is no triggering defined, neither periodic nor via transmissionTrigger).

6.16.2.2 Mapping description from several sources

The mapping setup in figure 6.140 shows an example of a true multi-source mapping definition: The content of *dataZ3* is composed out of several sources: *dataX* and *dataY*.

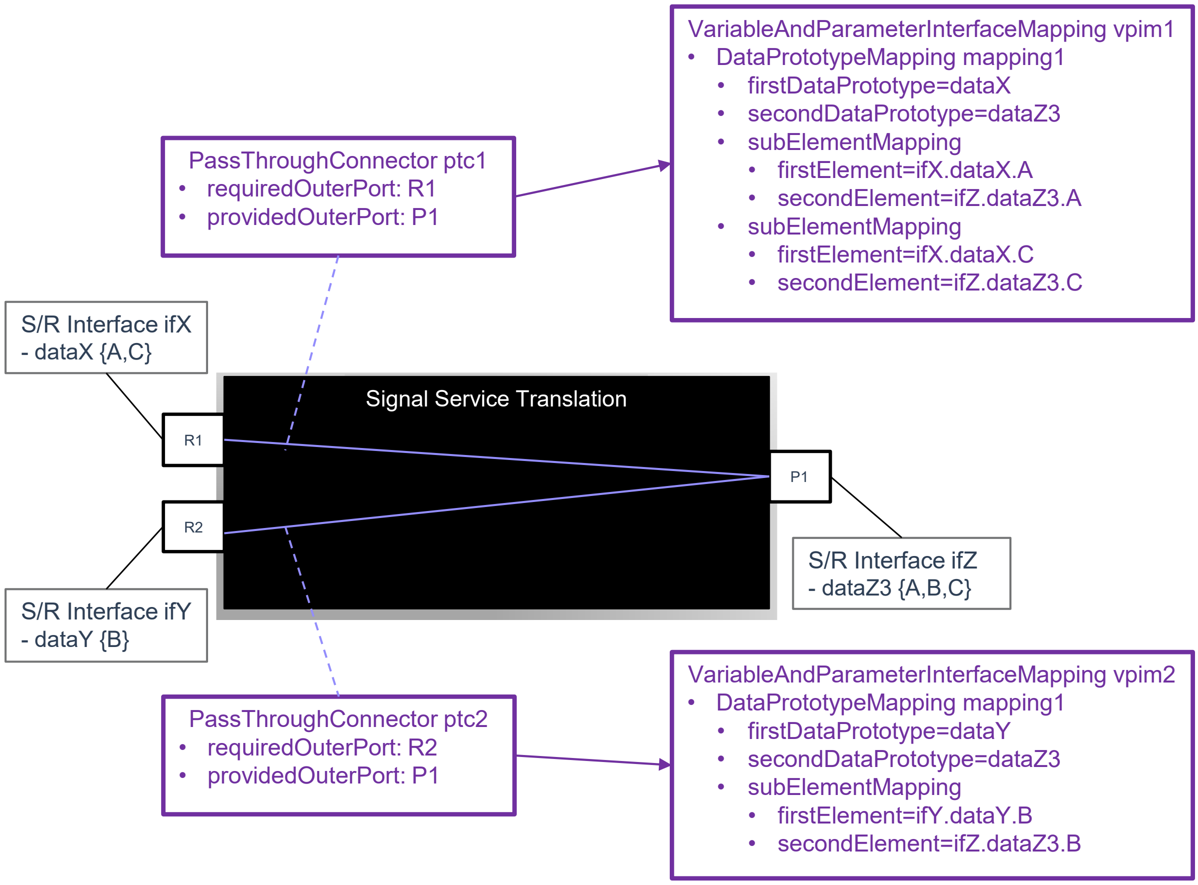

Figure 6.140: Mapping description using PassThroughSwConnectors and PortInterfaceMappings from several sources

The configuration of target data elements which are composed from several sources into the target data element is always defined from the perspective of the *target data element*.

The root of the *target data element* is defined by the reference SignalServiceTranslationEventProps.translationTarget. With this reference the SwComponentPrototype hosting the signal/service translation is defined, as well as the PPortPrototype, and the translationTarget VariableDataPrototype.

In case of signal/service translation from several sources the translationTarget VariableDataPrototype is composed out of several sources. But the definition of element translation attributes happens on the *target data elements*: SignalServiceTranslationElementProps is used to define transmissionTrigger and filter attributes for one leaf member of the translationTarget data element. In order to find the *source* data element to be translated the PassThroughSwConnectors and potential VariableAndParameterInterfaceMappings have to be considered as well.

Since the translationTarget may be composed from several sources a restriction applies to the swImplPolicy of the involved source data.

A setup where several source data elements have the attribute swImplPolicy set to queued leads to runtime issues, as - at the point in time when the translationTarget shall be composed - all the source data elements need to be gathered. But in case of a source data element where swImplPolicy is set to queued a source data element queue might be empty. An empty queue might have a variety of reasons, e.g. the rate at which the queue is filled is slower than the rate the signal/service translation consumes the data.

Thus it would be very unlikely that all the source data element queues have at least one element to be read and consumed at the point in time when the signal/service translation tries to read them.

[TPS_SYST_03059] At most one queued source input in case of signal/service translation from several sources

Upstream requirements: RS_SYST_00059

⌈If the SignalServiceTranslationEventProps.translationTarget is composed out of several sources then at most one of these sources shall have the attribute swImplPolicy set to queued.⌋

[TPS_SYST_03060] Source input with queued semantics shall have transmissionTrigger set to true

Upstream requirements: RS_SYST_00059

⌈If a source data element has the attribute swImplPolicy set to queued then the corresponding target SignalServiceTranslationElementProps shall have the attribute transmissionTrigger set to *true*.

This shall be the only SignalServiceTranslationElementProps which has transmissionTrigger set to true in the scope of the SignalServiceTranslationEventProps.⌋

Note: [TPS_SYST_03060] implies that only one source can be queued and that source shall be the only source which has the transmissionTrigger set to *true*.

The queued reception of a source data element might cause an issue (e.g., unclear behavior in case of empty queues or queue overruns) with the periodic reception (see [TPS_SYST_03042]) or sending (see [TPS_SYST_03043]). Thus this combination is not supported by the signal/service translation.

[TPS_SYST_03061] No support for queued reception semantics in combination with periodic communication

Upstream requirements: RS_SYST_00059

⌈If in the scope of a SignalServiceTranslationEventProps.translationTarget the translationTarget has a periodic sending defined according to

[TPS_SYST_03043] and/or at least one source data element has a periodic reception defined according to [TPS_SYST_03042] then none of the source data elements shall have a `queued` reception semantics.⌋

[TPS_SYST_03038] Definition of transmission triggers for translations with different sources

Upstream requirements: RS_SYST_00059

⌈The attribute `SignalServiceTranslationElementProps.transmissionTrigger` defines which translation elements (`SignalServiceTranslationElementProps.element`) contribute to the transmission triggering for the mapped payload.⌋

[TPS_SYST_03039] Full translation before transmission triggering

Upstream requirements: RS_SYST_00059

⌈In case there has been a transmission trigger caused by a source signal the `signal/service translation` shall process all other mapped source signals from the triggering source context (signal group or IPdu) before actually sending out the target.⌋

This basically means that for example if in the scenario depicted in figure 6.140 *dataZ3.B* were configured to trigger a transmission of *dataZ3*, then upon the reception event of *dataY* both *dataX* and *dataY* shall be received (by calling the corresponding RTE APIs), *dataZ3* shall be assembled out of the received *dataX* and *dataY* in order to fill *dataZ3.A*, *dataZ3.B*, and *dataZ3.C* with up-to-date information, and finally *dataZ3* shall be sent (by calling the corresponding RTE API).

[TPS_SYST_03040] Transmission trigger for translations with different sources

Upstream requirements: RS_SYST_00059

⌈If the attribute `SignalServiceTranslationElementProps.transmissionTrigger` equals *true* then
the reception of the respective source signal does cause the sending of the target (after all mapped sources from the same source context have been translated, see [TPS_SYST_03039]).⌋

[TPS_SYST_03041] No transmission trigger for translations with different sources

Upstream requirements: RS_SYST_00059

⌈If the attribute `SignalServiceTranslationElementProps.transmissionTrigger` is not defined or has the value *false* then
the reception of the respective source signal does not cause the sending of the target.⌋

6.16.2.3 Mapping description and data conversion

As the mapping for signal/service translation is implemented on Application level also the data conversion possibilities of the RTE may be used directly. [TPS_SWCT_01560] and [TPS_SWCT_01561] in the Software Component Template [4] define for which categorys of CompuMethods data conversion is supported.

6.16.2.4 Implementation of PassThroughSwConnectors

The definition of SignalServiceTranslationProps, PassThroughSwConnectors and potential VariableAndParameterInterfaceMappings specify the requirements what the signal/service translation shall do. The actual implementation needs to be done by code executed in the scope of a SwComponentPrototype typed by an AtomicSwComponentType.

Whether the SwComponentPrototype implementing the signal/service translation (typed by an AtomicSwComponentType) is put inside the CompositionSwComponentType which used to define the PassThroughSwConnectors or whether the SwComponentPrototype implementing the signal/service translation replaces the CompositionSwComponentType is left to the implementation.

The goal of this approach is that the model and the code of the signal/service translation AtomicSwComponentType can be automatically derived / generated from the requirements stated in the SignalServiceTranslationProps, PassThroughSwConnectors, and VariableAndParameterInterfaceMappings. This may include the definition of one or more

- ApplicationSwComponentType
- SwcInternalBehavior
- RunnableEntity
- VariableAccess

Figure 6.141 shows an example where the upper part illustrates the CompositionSwComponentType with PassThroughSwConnectors and VariableAndParameterInterfaceMappings. The lower part of the figure sketches an AtomicSwComponentType actually hosting the code which implements the signal/service translation.

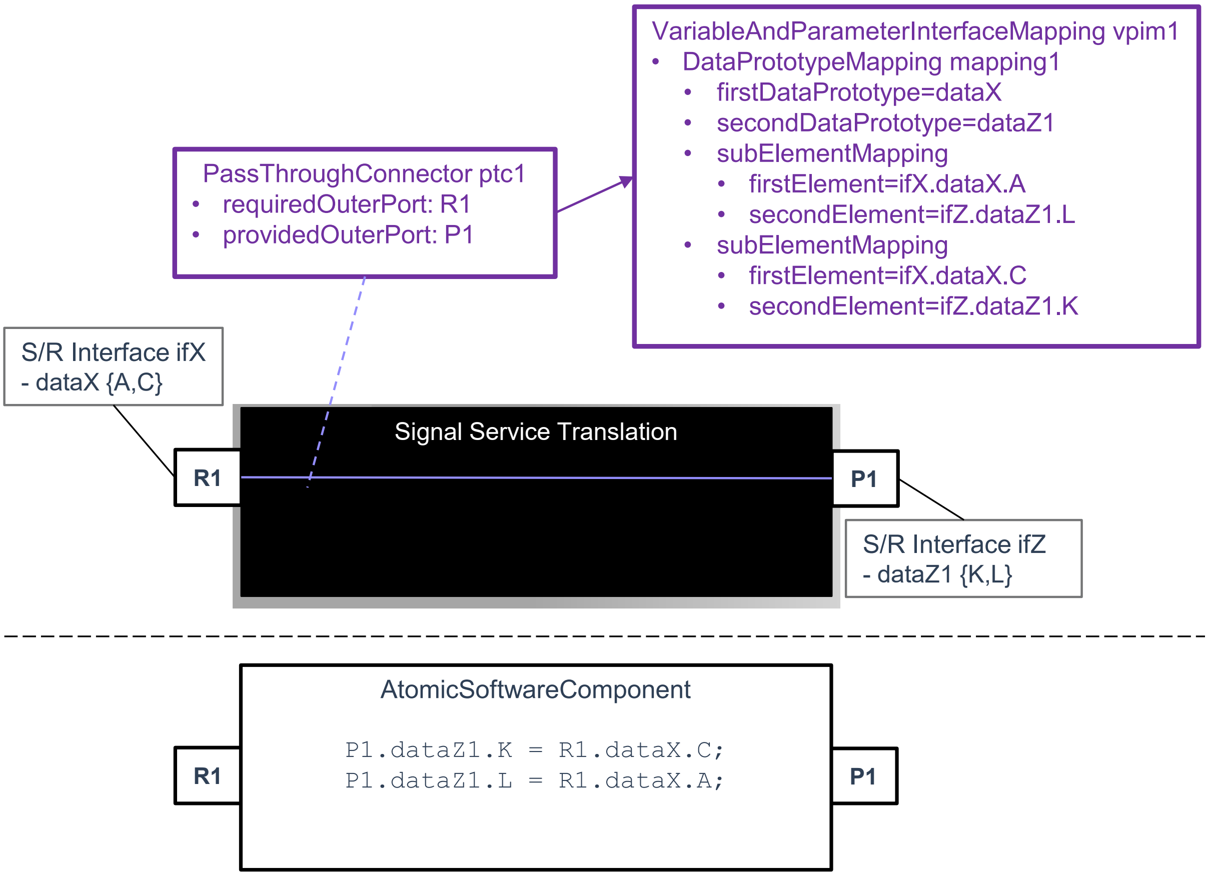

Figure 6.141: Implementation of PassThroughSwConnectors and PortInterfaceMappings

6.16.3 Service discovery control

The service discovery module [26] handles the offering/finding of service instances as well as the subscription to event groups. The behavior for each service instance may be controlled by Application software components via the BswM.

In scope of the `signal/service translation` the Translation Software Component needs to take control of the offering and subscribing to service instances. The general setup is illustrated in figure 6.142.

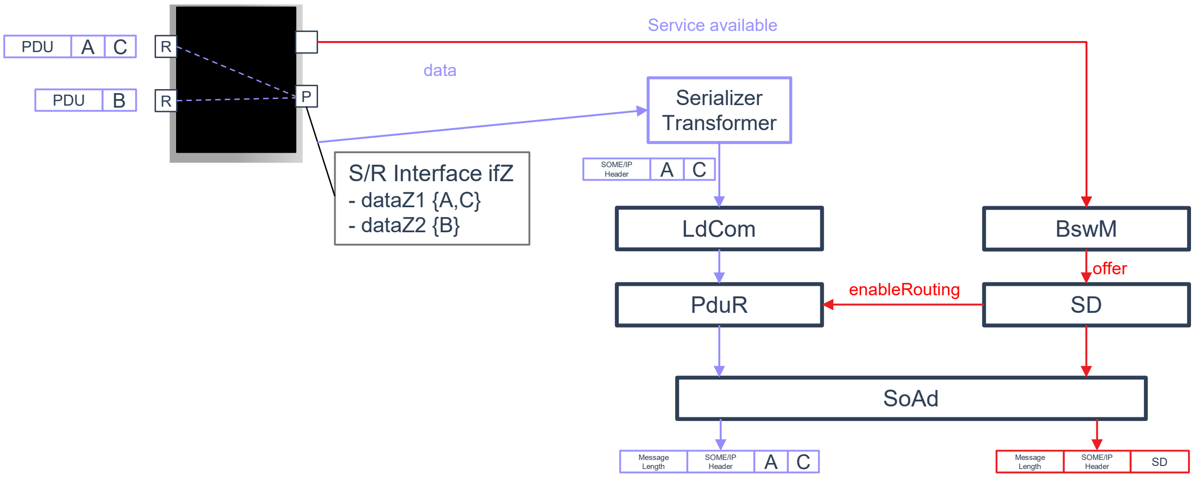

Figure 6.142: Interaction between translation SWC can Service Discovery

At which point in time a specific service instance (originating from signal/service translation) is actually offered / subscribed at the service discovery can be defined per service instance:

Possible approaches for service availability/subscription are:

- translationStart - start of ECU (see section 6.16.3.1)
- partialNetwork - availability of involved partial networks (see section 6.16.3.2)
- serviceDiscovery - availability of related service instance (see section 6.16.3.3)

The attribute SignalServiceTranslationProps.serviceControl defines the service instance control behavior.

Enumeration	**SignalServiceTranslationControlEnum**
Package	M2::AUTOSARTemplates::CommonStructure::SignalServiceTranslation
Note	This enumeration allows to define how the service instance offer/subscribe control shall behave.
Aggregated by	SignalServiceTranslationProps.serviceControl
Literal	**Description**
allPartialNetworks Active	Defines the start of service control when all specified partial networks are active. **Tags:** atp.EnumerationLiteralIndex=3
anyPartialNetwork Active	Defines the start of service control when any specified partial network is active. **Tags:** atp.EnumerationLiteralIndex=4
partialNetwork	Defines the start of service control when specific partial networks are active. **Tags:** atp.EnumerationLiteralIndex=1 atp.Status=obsolete
serviceDiscovery	Defines the start of service control when other service is available. **Tags:** atp.EnumerationLiteralIndex=2
translationStart	Defines the start of service control at translation start. **Tags:** atp.EnumerationLiteralIndex=0

Table 6.345: SignalServiceTranslationControlEnum

6.16.3.1 Service control at ECU start

The approach of service control at ECU start is to utilize the *AutoAvailable* / *AutoRequire* feature of the service discovery module where the service instance is automatically offered at startup of the ECU. In this case the translation software component does not need to interact with the BswM to control the service state of each individual service instance.

It is configurable per translated service event whether that event shall be automatically controlled at ECU start.

[TPS_SYST_03022] autoAvailable setting for provided service instance with translationStart

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals translationStart, then the ProvidedServiceInstance owning the EventHandler referenced by SignalServiceTranslationProps.controlProvidedEventGroup shall have its autoAvailable attribute set to *true*.⌋

[TPS_SYST_03023] autoRequire setting for required service instance with translationStart

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals translationStart, then the ConsumedServiceInstance owning the ConsumedEventGroup referenced by SignalServiceTranslationProps.controlConsumedEventGroup shall have its autoRequire attribute set to *true*.⌋

[TPS_SYST_03024] autoRequire setting for required event groups of required service instance with translationStart

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals translationStart, then the ConsumedEventGroup referenced by SignalServiceTranslationProps.controlConsumedEventGroup shall have its autoRequire attribute set to *true*.⌋

6.16.3.2 Service control due to availability of partial networks

If the availability of the signal-based PDUs is controlled using Partial Networking then the respective translated services offers/subscriptions can only be activated if the specific partial networks are active. This relationship is used to control the availability of specific service instances.

In case there are several PNCs referenced in the role SignalServiceTranslationProps.controlPnc the activation of the translated service can be configured to either

- activate the service when ANY of the referenced PNCs is available (SignalServiceTranslationProps.serviceControl equals SignalServiceTranslationControlEnum.anyPartialNetworkActive)
- activate the service when ALL of the referenced PNCs are available (SignalServiceTranslationProps.serviceControl equals SignalServiceTranslationControlEnum.allPartialNetworksActive).

[constr_3545] Mandatory reference to a *Pnc* in case of anyPartialNetworkActive or allPartialNetworksActive

Imposition time: IT_SysDesc

⌈If the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive or allPartialNetworksActive, then the reference SignalServiceTranslationProps.controlPnc shall point to at least one PncMappingIdent.⌋

[TPS_SYST_03025] Control of service instance in case of anyPartialNetworkActive or allPartialNetworksActive

Upstream requirements: RS_SYST_00059

⌈If the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive or allPartialNetworksActive, then the respective service instance shall be configured to be controlled using the BswM/SD configuration.⌋

The ComM states relevant for the activation are defined in the SWS document [37].

Requested Partial Network: respective PNC is in ComM status COMM_PNC_REQUESTED or COMM_PNC_READY_SLEEP.

Released Partial Network: respective PNC is in ComM status COMM_PNC_PREPARE_SLEEP or COMM_PNC_NO_COMMUNICATION.

[TPS_SYST_03026] Monitoring of the requested *partial networks* status in case of anyPartialNetworkActive for provided service instance

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive, then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If at least one of the referenced *partial networks* is in the state requested then the translation software component shall *offer* the respective translated service instance.⌋

[TPS_SYST_03027] Monitoring of the requested *partial networks* status in case of anyPartialNetworkActive for required service instance

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive, then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If at least one of the referenced *partial networks* is in the state requested then the translation software component shall *find* the respective translated service instance and *subscribe* to its event groups.⌋

[TPS_SYST_03056] Monitoring of the released *partial networks* status in case of anyPartialNetworkActive for required service instance

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive, then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If all of the referenced *partial networks* are in the state released then the translation software component shall *unsubscribe* from its event groups.⌋

[TPS_SYST_03057] Monitoring of the released *partial networks* status in case of anyPartialNetworkActive for provided service instance

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals anyPartialNetworkActive then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If all of the referenced *partial networks* are in the state released then the translation software component shall stop *offer*ing the respective translated service instance.⌋

[TPS_SYST_02380] Monitoring of the requested partial networks status in case of allPartialNetworksActive for provided service instance

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals allPartialNetworksActive, then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc). If all of the referenced *partial networks* are in the state requested then the translation software component shall *offer* the respective translated service instance.⌋

[TPS_SYST_02381] Monitoring of the requested partial networks status in case of allPartialNetworksActive for required service instance

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals allPartialNetworksActive, then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc). If all of the referenced *partial networks* are in the state requested then the translation software component shall *find* the respective translated service instance and subscribe to its event groups.⌋

[TPS_SYST_02382] Monitoring of the released *partial networks* status in case of allPartialNetworksActive for required service instance

Upstream requirements: RS_SYST_00059

⌈For a required translated service instance, if the SignalServiceTranslationProps.serviceControl equals allPartialNetworksActive then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If any of the referenced *partial networks* are in the state released then the translation software component shall unsubscribe from its event groups.⌋

[TPS_SYST_02383] Monitoring of the released *partial networks* status in case of allPartialNetworksActive for provided service instance

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals allPartialNetworksActive then the translation software component shall monitor the status of the referenced *partial networks* (referenced via SignalServiceTranslationProps.controlPnc).

If any of the referenced *partial networks* is in the state released then the translation software component shall stop *offer*ing the respective translated service instance.⌋

6.16.3.3 Service control due to availability of related service instance

There are scenarios where the transmission of signal-based PDUs is controlled by means of SOME/IP service discovery, i.e., the signal-based PDUs are effectively offered as events of a service and are only transmitted in case there are active subscriptions present. Since the payload of the signal-based PDUs is not serialized according to the SOME/IP transformer rules, even in such scenarios `signal/service translation` is required for the payload.

In this setup, however, the availability of the translated/target service instance depends on the availability of the corresponding source service instance(s). Note, that this dependency is irrespective of the actual direction of the translation:

- In case of *signal to service translation* the availability of the translated/target service instance (which exhibits a SOME/IP serialized payload) depends on the availability of the source service instance (which exhibits a signal-based payload).
- In case of *service to signal translation* the availability of the translated/target service instance (which exhibits a signal-based payload) depends on the availability of the source service instance (which exhibits a SOME/IP serialized payload).

Figure 6.143 illustrates an example setup showing exactly the above mentioned dependency in both directions as well as the approach to handle this dependency:

Service to signal translation (case a): A SOME/IP serialized source service instance shall be translated into a signal-based target service instance. Here the signal-based target service instance shall only be *offered* when the corresponding SOME/IP serialized source service instance is actually successfully subscribed to. Thus the approach is to initially issue a *find service* for the SOME/IP serialized source service instance. Upon the reception of an *offer service* a *subscribe event group* is sent and, finally, upon the reception of a *subscribe event group acknowledge* (i.e., upon the successful subscription) the signal-based translated target service instance is *offered*. For this setup the `ConsumedEventGroup` representing the SOME/IP serialized source service instance of *Ra* is used as `controlConsumedEventGroup`.

Signal to service translation (case b): A signal-based source service instance shall be translated into a SOME/IP serialized target service instance. Here the SOME/IP serialized target service instance shall only be *offered* when the corresponding signal-based source service instance is actually successfully subscribed to. The approach is analoguous to case *a* with source/target roles reversed. For this setup the `ConsumedEventGroup` representing the signal-based source service instance of *Rb* is used as `controlConsumedEventGroup`.

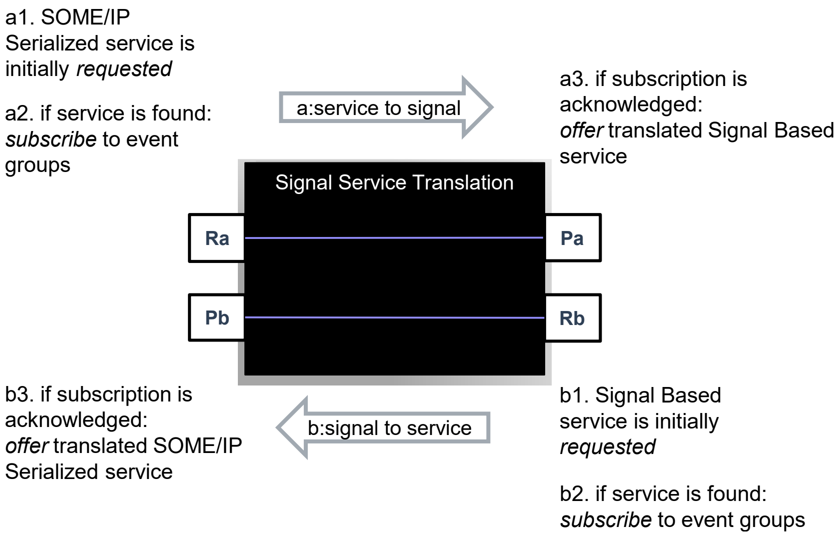

Figure 6.143: Translation based on service availability

[constr_3546] Mandatory reference to a ConsumedEventGroup in case of serviceControl

Imposition time: IT_SysDesc

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals serviceDiscovery then the reference SignalServiceTranslationProps.controlConsumedEventGroup shall point to at least one ConsumedEventGroup.⌋

In case SignalServiceTranslationProps.serviceControl is set to serviceDiscovery then the ConsumedEventGroups referenced in role controlConsumedEventGroup as well as the owning ConsumedServiceInstances are required for the availability of the provided translated service instance and thus have to be *found* and *subscribed to* by means of *find service* and *subscribe event group*. This *finding* and *subscription* is automatically (i.e., without the need of any SWC intervention) achieved by having the ConsumedServiceInstance and the ConsumedEventGroup autoRequire their instances.

[TPS_SYST_03028] *Auto require* for controlConsumedEventGroup in case of service instance with serviceControl

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals serviceDiscovery then every ConsumedEventGroup referenced in SignalServiceTranslationProps.controlConsumedEventGroup shall have the autoRequire attribute set to *true*.⌋

[TPS_SYST_03058] *Auto require* for ConsumedServiceInstance in case of service instance with serviceControl

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals serviceDiscovery then the every ConsumedServiceInstance owning at least one of the controlConsumedEventGroups shall have the autoRequire attribute set to *true*.⌋

[TPS_SYST_03029] *Offer* for a provided translated service instance with serviceControl

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals serviceDiscovery and the *subscribe* to **all** referenced controlConsumedEventGroups was successful, then the respective translated target service instance shall be *offer*ed. This applies for both, signal-service-translation as well as service-signal-translation.⌋

[TPS_SYST_03030] *Stop offer* for a provided service instance with serviceControl

Upstream requirements: RS_SYST_00059

⌈For a provided translated service instance, if the SignalServiceTranslationProps.serviceControl equals serviceDiscovery and the *subscription* of **at least one** controlConsumedEventGroup is not available, then a *stop offer* of the respective translated target service instance shall be issued. This applies for both, signal-service-translation as well as service-signal-translation.⌋

6.16.4 Translation behavior

There are two possible ways to define behavioral aspects for the signal/service translation use-case:

- COM-Stack
- Translation Application Software Component

6.16.4.1 COM-Stack translation behavior

The Classic platform COM-Stack can be configured to have an own periodic behavior for periodic sending and reception/time-out monitoring. In this case the existing COM-Stack definition of behavior is used.

Example features are:

- TransmissionModeTiming.cyclicTiming
- TransmissionModeTiming.eventControlledTiming
- IPduTiming.minimumDelay
- ISignalPort.timeout

Thus it is possible to register the Translation Application Software Component to be notified when data arrives and then perform the translation operation solely driven by the notifications from the COM-Stack.

There are use-cases where the COM-Stack can not be used to perform the specific behavioral aspects because the Transformers are required to have access to the raw received and sent data. In these cases the usage of the Translation Application Software Component behavior is required.

6.16.4.2 Translation Application Software Component translation behavior

If the Translation Application Software Component shall implement specific behavioral aspect these have to be defined at the definition of the CompositionSwComponentType which has the signal/service translation input and output PortPrototypes as well as the PassThroughSwConnectors.

For the periodic behavior the definition of SenderComSpec.transmissionProps.dataUpdatePeriod and ReceiverComSpec.receptionProps.dataUpdatePeriod define the expected periods for data update and check.

[TPS_SYST_03042] Periodic call in case of ReceiverComSpec.ReceiverComSpec.receptionProps.dataUpdatePeriod

Upstream requirements: RS_SYST_00059

⌈If the signal/service translation CompositionSwComponentType has a RPortPrototype defined with a ReceiverComSpec.receptionProps.dataUpdatePeriod defined then
the signal/service translation software component implementation shall periodically call the respective Rte reception API with the defined period.⌋

[TPS_SYST_03043] Periodic call in case of SenderComSpec.transmissionProps.dataUpdatePeriod

Upstream requirements: RS_SYST_00059

⌈If the signal/service translation CompositionSwComponentType has a PPortPrototype defined with a SenderComSpec.transmissionProps.dataUpdatePeriod defined then
the signal/service translation software component implementation shall periodically call the respective Rte sending API with the defined period.⌋

Data filtering:

If there is a filter defined at the NonqueuedReceiverComSpec then the evaluation of this DataFilter is performed in the COM-Stack. Thus the COM-Stack filtering usually can not be applied when there are transformers involved because the state machines of E2E transformers need to receive every message.

If a data filtering shall be applied *after* the data transformation inside the signal/service translation software component then there is the possibility to define a DataFilter at the SignalServiceTranslationElementProps in the role filter.

[TPS_SYST_03051] Data filter inside the signal/service translation software component

Upstream requirements: RS_SYST_00059

⌈If there is a SignalServiceTranslationElementProps.filter defined this filtering shall be implemented inside the signal/service translation software component.⌋

6.16.5 End-to-End considerations

In case there is an E2E header attached and/or a secure communication defined the translation needs to break the transport chain and re-calculate the E2E measures (CRC/MAC). The CRC/MAC is calculated over the uint8 array representation of the payload data. Since the signal/service translation changes the data layout, also the uint8 array representation of the payload data changes resulting in a different CRC/MAC value.

6.16.5.1 Safety

Due to the architectural approach of the signal/service translation the safety aspects can be configured using existing mechanisms. Thus it is possible to define dedicated safety end-to-end profiles for both the signal-based part, and the service-based part. The translation software component then links the two parts together and handles the behavioral aspects of the translation.

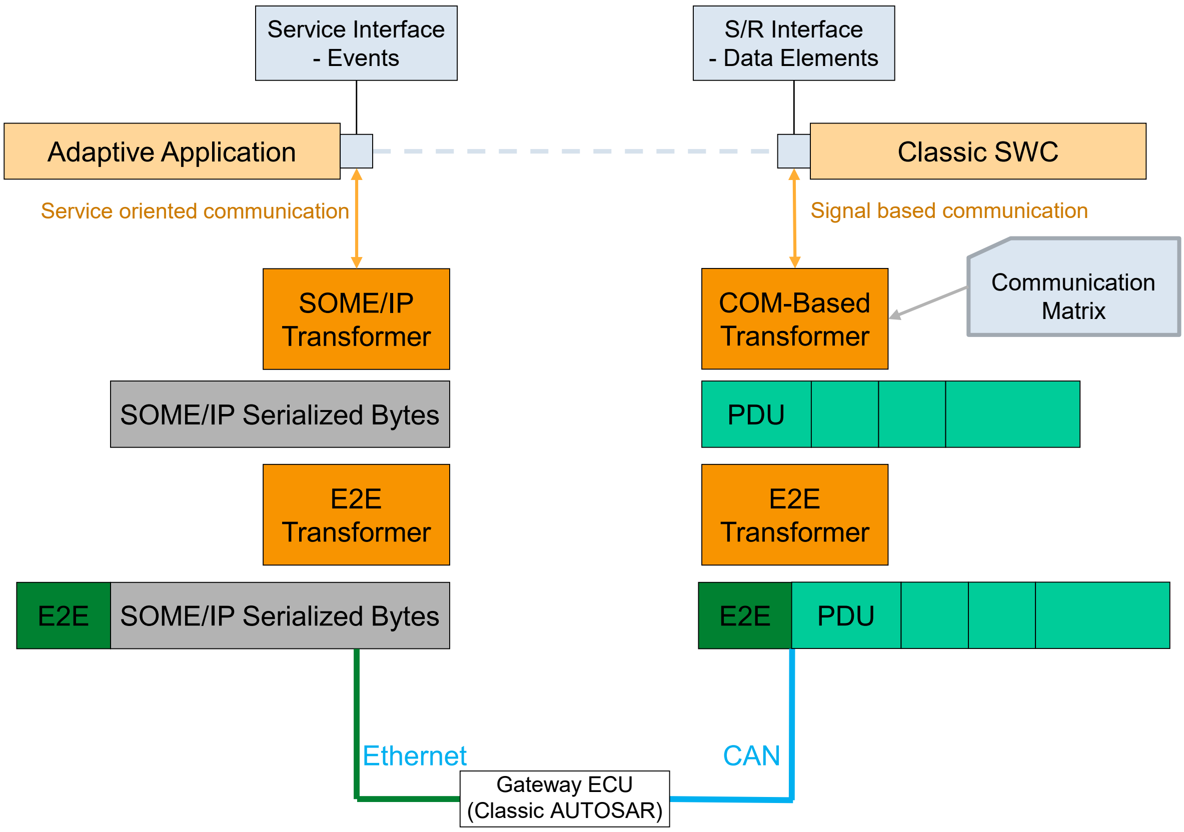

Figure 6.144: Signal/Service Translation and Safety

The attribute SignalServiceTranslationEventProps.safeTranslation is used to explicitly require that both ends of the translation shall be configured in a safe transport way and that the translation software component shall handle the translation activity in a end-to-end preserving way.

[TPS_SYST_03044] Handling of safe signal/service translation in one software component

Upstream requirements: RS_SYST_00059

⌈It is required that the signal/service translation (and vice versa) of one Service/SignalGroup pair which are mapped to each other, shall be handled in one software component to also cover a closed mapping from one E2E profile to another, if necessary. The signal/service translation of different (independent) Services/SignalGroups may be handled by different software component.⌋

[TPS_SYST_03036] PortAPIOption for safeTranslation RPortPrototype

Upstream requirements: RS_SYST_00059

⌈If SignalServiceTranslationEventProps.safeTranslation is set to *true* then a PortAPIOption referring to the RPortPrototype shall exist and the PortAPIOption.errorHandling attribute shall be set to transformerErrorHandling.⌋

[TPS_SYST_03037] PortAPIOption for safeTranslation PPortPrototype

Upstream requirements: RS_SYST_00059

⌈If SignalServiceTranslationEventProps.safeTranslation is set to *true* then a PortAPIOption referring to the PPortPrototype shall exist and the PortAPIOption.transformerStatusForwarding attribute shall be set to transformerStatusForwarding.⌋

[TPS_SYST_03045] Support for safe signal/service translation

Upstream requirements: RS_SYST_00059

⌈The translation of E2E protected data shall be supported in both directions, signal-service-translation and service-signal-translation.⌋

[TPS_SYST_03046] Support for safe signal/service translation with same or different E2E profiles

Upstream requirements: RS_SYST_00059

⌈The translation of E2E protected data shall support the occurrence of

- the same E2E profile on both sides of the communication and
- different E2E profiles on each side of the communication.

⌋

[TPS_SYST_03047] 1:n mapping for E2E protected data

Upstream requirements: RS_SYST_00059

⌈It shall be possible to map the same E2E protected source data to several E2E protected target data (1:n).⌋

[TPS_SYST_03048] E2E protected target out of E2E protected sources

Upstream requirements: RS_SYST_00059

⌈The content of one E2E protected target shall only be composed out of data from E2E protected sources.⌋

The rationale for [TPS_SYST_03048] is to support the use-case where target data shall be E2E protected and is composed from several sources.

[TPS_SYST_03049] No translation of not OK E2E protected composed data

Upstream requirements: RS_SYST_00059

⌈If a E2E protected source data is mapped into a composed E2E protected target data and
if the E2E-Check for the source data returns any E2E error (not *E_OK*) then

this source data shall not be forwarded to the respective target data and (if applicable) shall not trigger the transmission of the target.⌋

If source data is not verified as *E_OK* it is not translated into a composed target. If the translated E2E protected data comes from several sources there may occur correlation and synchronicity issues during translation.

[TPS_SYST_03031] Sufficient ASIL level of translation software component

Upstream requirements: RS_SYST_00059

⌈If the `SignalServiceTranslationEventProps`.`safeTranslation` equals true then the implementation of the translation software component shall fulfill a sufficient ASIL.⌋

[constr_3548] EndToEnd profile for both ends of `safeTranslation`

Imposition time: `IT_SysDesc`

⌈If the `SignalServiceTranslationEventProps`.`safeTranslation` equals true then both, the signal-based payload as well as the service-oriented payload shall have an EndToEnd profile defined.⌋

[TPS_SYST_03032] Data transmission in case of *E_OK* safe signal reception

Upstream requirements: RS_SYST_00059

⌈`Signal/service translation` shall check the end-to-end status of every received payload. If the safety transformer returns *E_OK* for the received payload then the data shall be forwarded to the respective sending of the translation software component.⌋

Error handling:

[TPS_SYST_03033] No data transmission in case of reception timeout

Upstream requirements: RS_SYST_00059

⌈If no message is received within the specified message cycle time (timeout is detected), then no data shall be translated to the respective sending of the translation software component.⌋

[TPS_SYST_03034] Handling safe signal reception

Upstream requirements: RS_SYST_00059

⌈

Source error	Forwarding status code	Comment

The behavior of transformer status code forwarding (Error to Forwarding status code mapping)

⌋

6.16.5.2 Security

The security aspects are handled in the communication stack of Classic platform. There are two technologies for secure communication available:

- Secure Onboard Communication (SecOC) [38]
- Transport Layer Security (TLS) [39]

Which security technology is used for a translated service instance is up to the communication design. The security settings have to match between the providers and the consumers on the network.

As on Classic platform the translation happens on the application software component level it is possible to have equal, similar, or different security technologies configured on signal and service level (which is part of the COM-Stack configuration).

It is for instance well possible to have signals coming from a CanFD network secured with SecOC and translated into a service which is secured using TLS on Ethernet. But also using SecOC on Ethernet is possible.

In any case, if secure communication is involved together with signal/service translation the translation needs to break the transport chain and re-secure the payload (e.g. re-calculate the MAC for the newly serialized payload).

The attribute SignalServiceTranslationEventProps.secureTranslation is used to explicitly require that both ends of the translation shall be configured in a secure transport way and that the translation software component shall handle the translation activity in a security-preserving way.

[constr_3549] Secure payload for both ends in case of secureTranslation

Imposition time: IT_SysDesc

⌈If the SignalServiceTranslationEventProps.secureTranslation equals true then both, the signal-based payload as well as the service-oriented payload shall have a secure communication defined.⌋

7 Data Transformation

7.1 Outline

The transmission of data over a communication bus requires some effort to convey the information about the nature of the transmitted data from the sender to the receiver. Both sides need to agree on this part or else the communication will fail.

This aspect is complicated by the fact that in most cases it is uncommon to transmit information in an atomic manner piece by piece. For the sake of properly utilizing the available communication resources, pieces of data that may or may not have any semantic relationship with each other are packed into a single transmission unit.

In this case, the receiver does not only have to be informed about the nature of the individual pieces of information but also about the packing of these pieces into the transmission unit.

There are different approaches of how this goal can be achieved, these are described in the following sub-chapters.

7.1.1 Configuration of the Communication Layout

Use a configurable software package on both the sender and the receiver side that can adapt to virtually any possible packing of data. In this case the packing shall be described in machine-readable form on a very detailed level in order to allow for the communication software to adapt to it.

For the sake of this argument, it doesn't really matter whether the adaption to the configuration is done at run-time or whether the configuration ends up in dedicated source code. The point is that the very detailed machine-readable configuration description is required to exist.

This approach used to be one of the pillars of the AUTOSAR standard as it entitled the players in the business with a maximum amount of flexibility and especially the OEMs are able to develop specific patterns for the design of their communication matrices that can, despite the diversity, be expressed with this approach.

This approach also facilitates the monitoring of transmission during development and deployment of the automotive software because monitoring tools can use the same configuration information to set themselves up for the task. This aspect is very important for debugging and quality assurance.

The downside, however, is that the act of laying out pieces of information in a limited number of transmission units becomes cumbersome and time-consuming. This effect becomes even more prominent with the advent of more advanced communication technologies that allow for a much bigger payload in single transmission units.

7.1.2 Data Transformation by Software

Don't care about the individual layout of information on the bus and let a piece of software take care of marshaling data onto the communication bus on the sender side and the reverse process on the receiver side.

This approach gains attractiveness in an environment where large and complicated pieces of information need to be transmitted.

Of course, in order to make this approach work it is necessary to standardize the behavior of the marshaling software to the necessary extent such that sender and receiver agree on how data needs to be processed.

With this approach, the amount of configuration can be reduced dramatically at the potential expense of efficiency and code size.

But this is not the end of the story as the idea of letting software take care of data "manipulation" can **following pretty much the same pattern** be utilized for further use cases:

End-to-end Protection Data is wrapped into a harness of meta-data that allows for checking data integrity at the receiver side.

Data Security Data is cryptographically processed such that it shall become impossible for unauthorized parties to intercept the communication process.

In other words, the approach is not limited to marshaling of data but can in the same way also be used for an array of other useful data transformations. This is why the terminology in this regard is not limited to the marshaling but to data transformation in general, hence the term **`Data Transformer`** is coined.

`Data Transformer`s can be chained such that, on the sender side, one `Data Transformer` picks up the result of the transformation of another `Data Transformer` and applies a specific transformation to the already processed data.

The receiver then is required to apply the `Data Transformer`s in reverse order in order to finally yield the actual data and provide it to the consumer (e.g. an `ApplicationSwComponentType`).

A basic principle of the `Data Transformer` approach, however, is that the `Data Transformer` is only responsible for the actual data transformation but **not** concerned about the communication of data. This can be taken care of by other software modules.

In total, the second approach provides a sufficient level of utility that it becomes part of the AUTOSAR standard. This chapter lays out the details of how `Data Transformer`s can be used in the context of this document.

Further information can also be found in the SWS RTE [40].

7.2 Use Cases

This chapter describes Transformer use cases that are supported by AUTOSAR.

7.2.1 Transmission of large composite data types over networks with large PDUs (e.g Ethernet)

With a serializing transformer, it is not necessary any more to map the atomic sub-elements of composite data types to individual signals in the RTE. The sending application SWC sends the composite data element using Sender/Receiver communication and hands the data over to the RTE. Then the complex data get transformed to a linear byte array and handed over to Com which sends the data to the receiving ECU. There, the Com stack receives the serialized data and notifies the RTE. The Rte reads the data and calls the deserializing transformer. The deserializing transformer transforms them back into the composite data element and gives the result to the RTE. The receiving SWC can now read the data and access it in the same form the sending SWC has sent them.

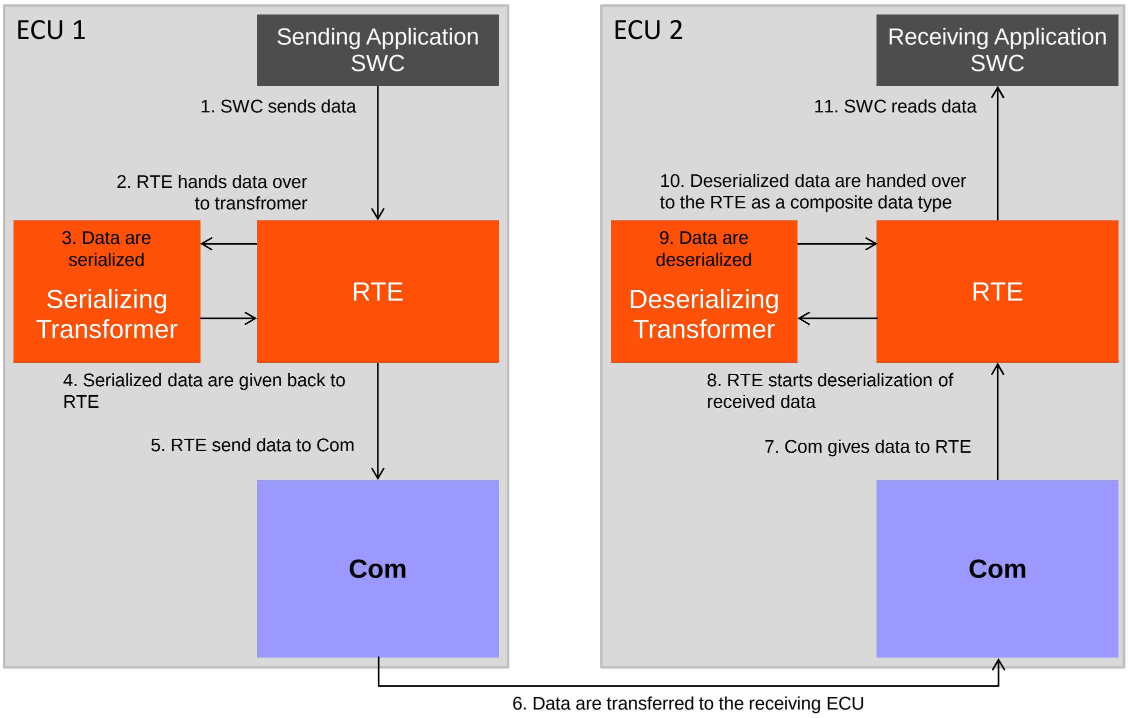

Figure 7.1: Transformer Use Case: Transmission of large composite data types over networks with large PDUs (e.g Ethernet)

7.2.2 Support of transmission from one sender to multiple receivers with Signal Fan-out

If a signal fan-out is configured in the System Description, the RTE has to hand over the data which should be transmitted multiple times to the Com stack. This is the case if multiple ISignals reference the same SystemSignal in the System Description.

For each ISignal the following steps have to be performed individually:

- transform the data
- hand it over to COM

Every receiver has to deserialize the ISignal in its transformer independently.

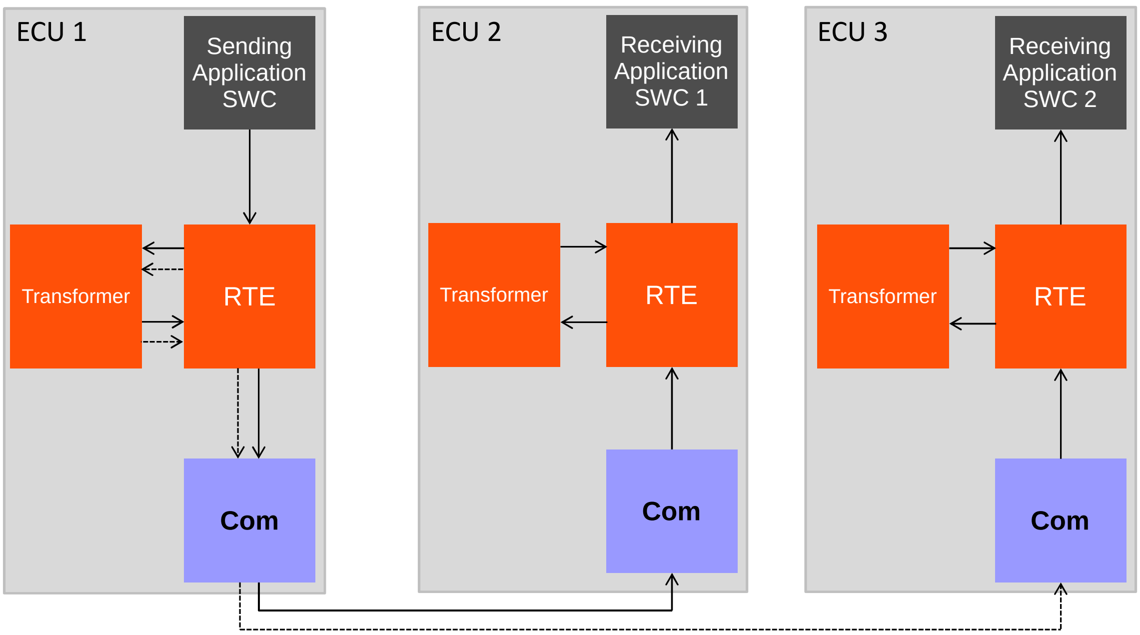

Figure 7.2: Transformer Use Case: RTE Fanout

7.2.3 Support of transmission from one sender to multiple receivers with PDU Fan-out

The transformation of inter-ECU Sender/Receiver communication should also work together with configurations that include Pdu fan-outs inside the COM stack (PduR fan-out). This is the case if multiple PduTriggerings reference the same Pdu in the System Description. In that scenario the data are sent by the sending application SWC to the RTE and transformed by the data transformer which is called by the RTE. Then the RTE hands the data over the Com. This happens only once. Due to the Pdu fan-out, the PduR sends the data multiple times to the Bus Interfaces using different Pdus.

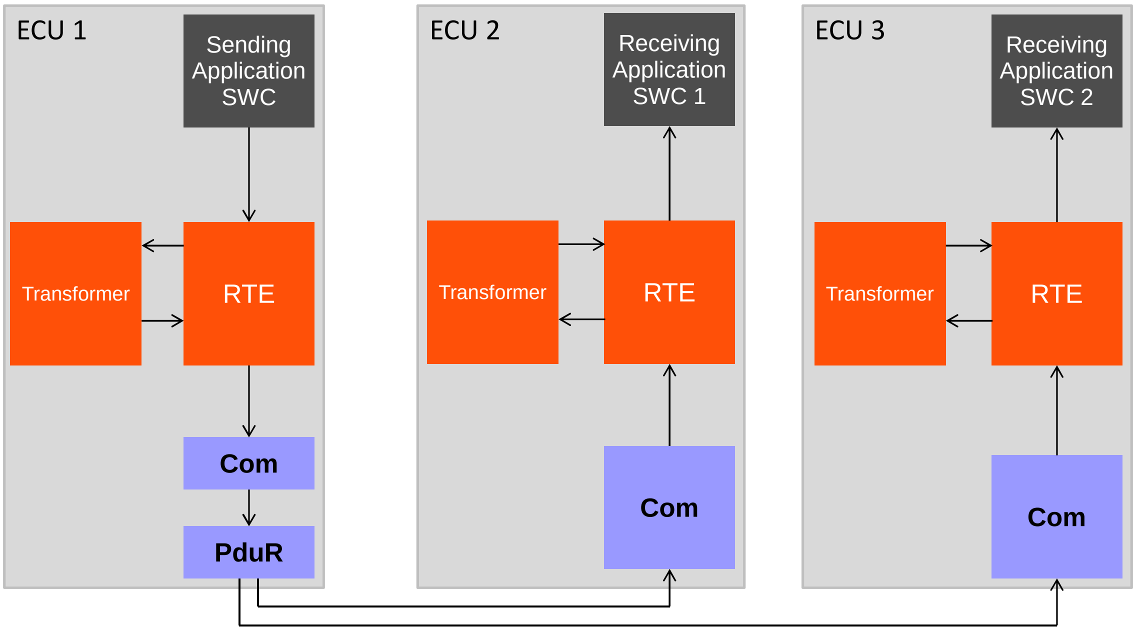

Figure 7.3: Transformer Use Case: PduR Fanout

7.2.4 Transformer Chaining

It is possible to chain multiple transformers. The output of one transformer then will be the input of the next transformer in the chain. Transformer for serialization data, for encrypting, digitally signing or compressing data can be implemented and used together. Such architecture could be used to assemble a system, where you can flexibly add functionality like compression or encryption to a serialized stream. In AUTOSAR the E2E-protection is implemented by an additional serializer which is appended to the chain.

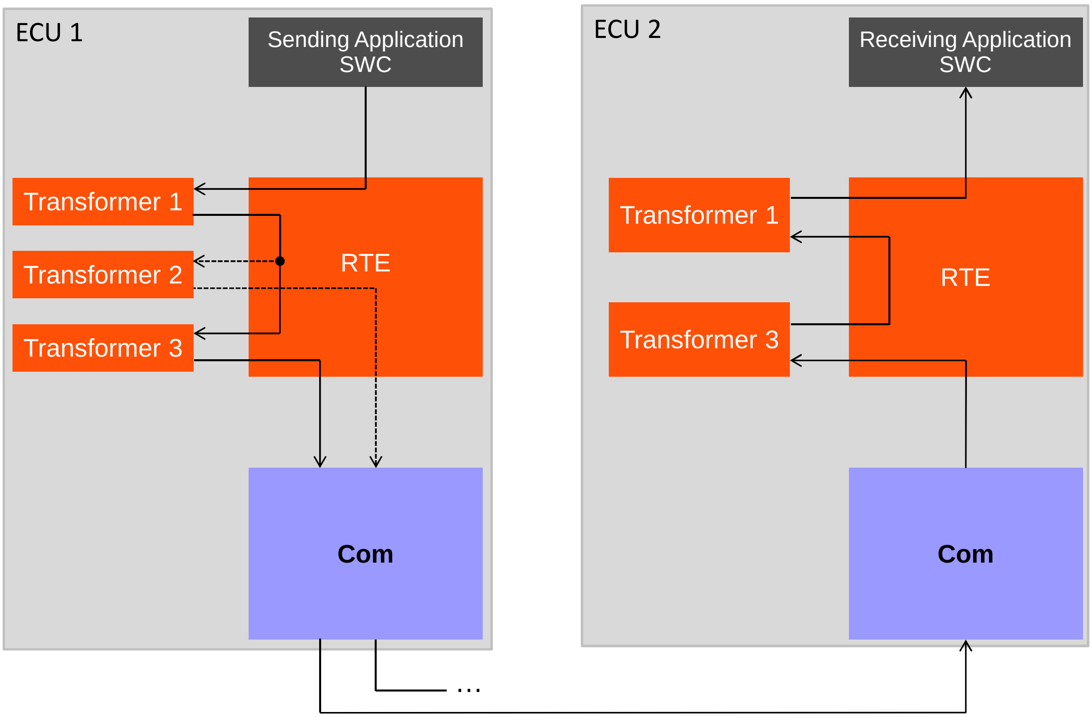

Figure 7.4: Transformer Use Case: Transformer Chain

7.2.5 Signal Group Based interaction of the transformer with the Com module

An initial transformer (serializer) performs the serialization according to the ISignal-ToIPduMapping from the system description. For each application data element the corresponding mapping to an ISignalIPdu position is respected. After the transformation chain is processed the serialized data is provided to the Com module. The Com module can have a signal based transmission mode selection defined and determines the respective transmission mode to be applied.

7.3 Transformer configuration

As a transformer provides well defined function signatures per each communication relation (ISignal based), which is marked for transformation, the function signature is NOT dependent from the transformation technology used, but only from the transmitted data elements (Client/Server operation signature or Sender/Receiver interface signature). The output of a transformer will be always a linear byte array.

Configuration of data transformation consists of three parts:

1. definition of the transformer chains with their transformers
2. configuration which communication is subject to transformation

3. configuration of the transformer properties for the transformed communication

The configuration of single transformers and whole transformer chains is shown in figure 7.5.

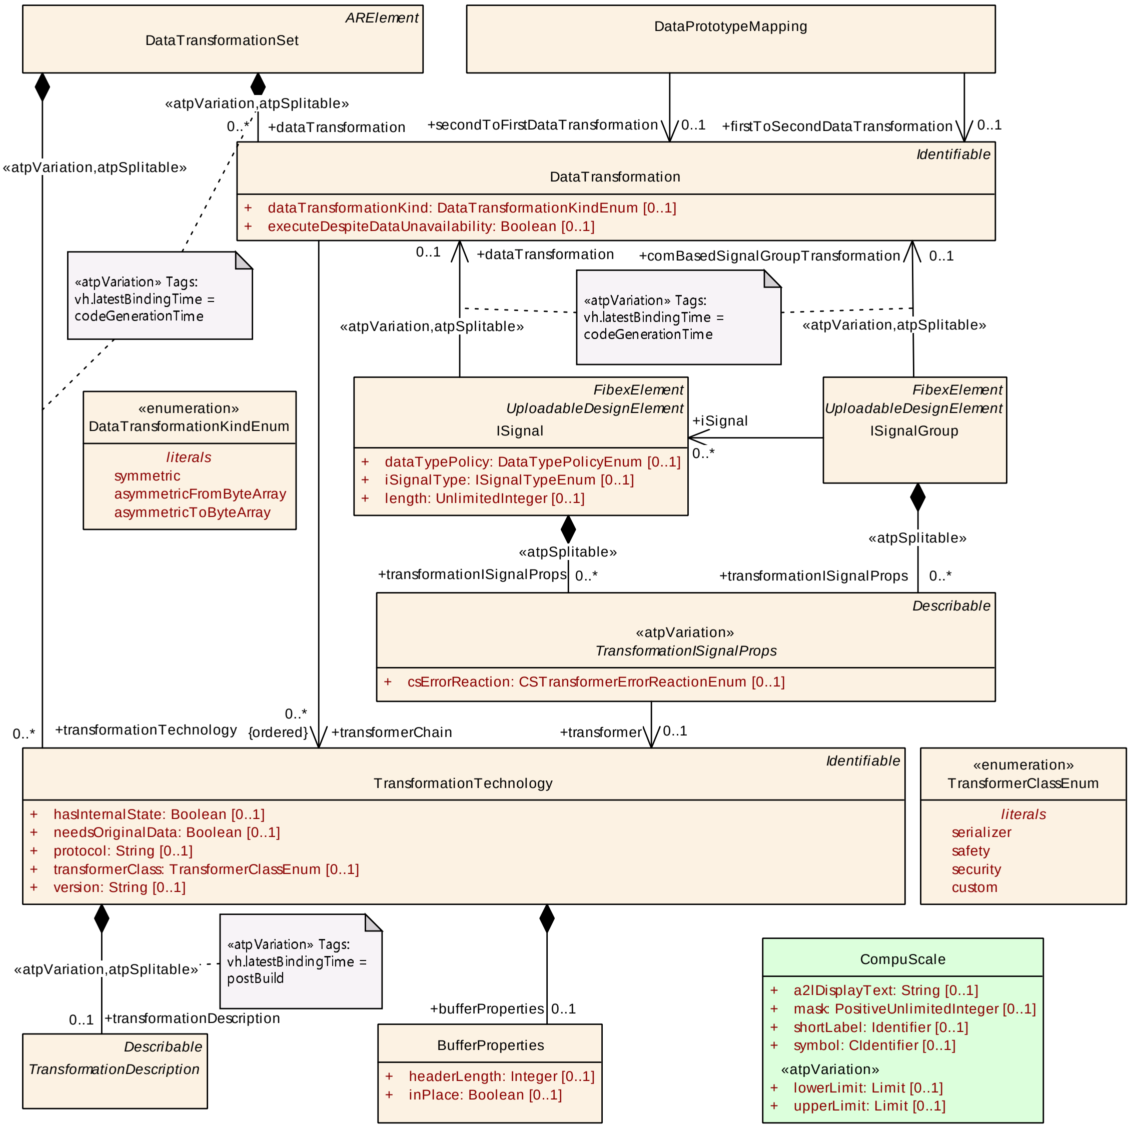

Figure 7.5: Configuration of transformers and transformer chains

The DataTransformationSet acts as a central container for the configuration of data transformation.

Class	**DataTransformationSet**
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer

transformer Chain (ordered)	Transformation Technology	*	ref	This attribute represents the definition of a chain of transformers that are supposed to be executed according to the order of being referenced from DataTransformation.

Table 7.2: DataTransformation

[TPS_SYST_02030] The `DataTransformationSet` contains all transformer chains

Upstream requirements: RS_SYST_00050

⌈The `DataTransformationSet` contains transformer chains represented by `DataTransformation` elements.⌋

For each transformer chain it can be decided via the attribute `executeDespiteDataUnavailability` whether the RTE should try to execute the transformers of the transformer chain, even when no data are available as input. e.g. the queue is empty or there was an error in the COM stack. This is needed when no data are available but a transformer has to be executed anyway because it maintains an internal state which has to be updated to consider that data was expected but not available.

This might be used in transformers which maintain an internal state. Of course the specifications and implementations of all transformers in the chain have to be able to cope with execution without valid input data.

[constr_3208] executeDespiteDataUnavailability usage restriction

Imposition time: IT_SysDesc

⌈In the set of more than one ISignal which reference the same SystemSignal in the role systemSignal, there shall be no ISignal which references a DataTransformation where executeDespiteDataUnavailability is set to true.⌋

In other words: There shall be no transformer chain which "belong" to the same SystemSignal due to signal fan-in where the attribute executeDespiteDataUnavailability is set to true.

[constr_9273] Existence of DataTransformation.executeDespiteDataUnavailability

Imposition time: IT_SysDesc

⌈For each DataTransformation, the attribute executeDespiteDataUnavailability shall exist.⌋

[constr_9274] Existence of DataTransformation.transformerChain

Imposition time: IT_SysDesc

⌈For each DataTransformation, at least one reference to TransformationTechnology in the role transformerChain shall exist.⌋

[TPS_SYST_02031] A transformer is represented by a TransformationTechnology

Upstream requirements: RS_SYST_00050

⌈A transformer is represented by a TransformationTechnology.⌋

Class	**TransformationTechnology**

security	The transformer is a security transformer. **Tags:** atp.EnumerationLiteralIndex=2
serializer	The transformer is a serializing transformer. **Tags:** atp.EnumerationLiteralIndex=3

Table 7.4: TransformerClassEnum

[constr_3265] TransformationTechnology.hasInternalState setting for an E2E transformer

Imposition time: IT_SysDesc

⌈The value of hasInternalState shall be set to true for a TransformationTechnology with transformerClass set to safety.⌋

[constr_3266] TransformationTechnology.hasInternalState setting for a SOME/IP Transformer

Imposition time: IT_SysDesc

⌈The value of hasInternalState shall be set to true for a SOME/IP Transformer if the ISignal that is referencing this transformer is mapped into an ISignalIPdu and this ISignalIPdu is referenced by a PduTriggering that in turn is referenced by a SomeipTpConnection in the role tpSdu.⌋

In other words the TransformationTechnology.hasInternalState has to be set to true in case that SOME/IP TP is used.

[TPS_SYST_02032] Transformer chains are ordered list of transformers

Upstream requirements: RS_SYST_00050

⌈A transformer chain consists of an ordered list of TransformationTechnologys (transformers).⌋

[constr_3121] The length of transformer chains is limited to 255 transformers

Imposition time: IT_SysDesc

⌈The maximum number of DataTransformation.transformerChain references in the context of one DataTransformation shall be limited to 255.⌋

[constr_3122] At most one transformer of each transformer class inside a transformer chain

Imposition time: IT_SysDesc

⌈If the value of a transformerClass of a TransformationTechnology referenced by a DataTransformation does not equal custom, it shall be different from all other transformerClass values of TransformationTechnologys referenced by the same DataTransformation.⌋

Only for custom transformers it is possible to specify more than one transformer of the same class in the same transformer chain. For all other transformer classes, at most one transformer of a transformer class is allowed to exist in the same transformer chain.

[constr_3123] Serializer transformer shall be the first in a chain

Imposition time: IT_SysDesc

⌈A serializer transformer (TransformationTechnology with attribute transformerClass set to serializer) shall be the first transformer in a transformer chain.⌋

[TPS_SYST_02033] Order of the transformerChain references in the configuration represents the order on the sending side

Upstream requirements: RS_SYST_00050

⌈The order of DataTransformation.transformerChain references in the context of one DataTransformation represents the transformation order on the sending side.⌋

[TPS_SYST_02034] Order of the transformers on the receiving side is the reverse of the sending side

Upstream requirements: RS_SYST_00050

⌈The order of the transformers on the receiving side of the data shall be the inverse order of the order of the sending side.⌋

[TPS_SYST_02035] protocol contains the human readable protocol identifier

Upstream requirements: RS_SYST_00050

⌈The attribute protocol of a TransformationTechnology contains the protocol name as a String which this transformer implements.⌋

This attribute is used to distinguish transformers in a human readable way.

[TPS_SYST_02036] version contains the version of the protocol

Upstream requirements: RS_SYST_00050

⌈The attribute version of a TransformationTechnology contains the version of the protocol as a String implemented by this transformer.⌋

This attribute is used to distinguish transformers.

[TPS_SYST_02037] The attribute needsOriginalData configures a transformer's access to the original data

Upstream requirements: RS_SYST_00050

⌈The attribute needsOriginalData of a TransformationTechnology specifies whether transformer needs access to the original data.⌋

If it is set to true, the transformer will gain access to the original data. If it is set to false, the transformer will not gain access to the original data.

[constr_3124] Applicability of needsOriginalData

Imposition time: IT_SysDesc

⌈The attribute needsOriginalData of a TransformationTechnology shall only be used for the non-first transformers in the transformer chain.⌋

This will only influence the signatures of the transformer on the sender or client side, not on the receiver or server side of a communication.

[TPS_SYST_02038] Specification of transformer class

Upstream requirements: RS_SYST_00050

⌈The transformer class to which this transformer belongs to is specified in the attribute transformerClass of a TransformationTechnology⌋

[TPS_SYST_02039] Specification of transformer specific properties

Upstream requirements: RS_SYST_00050

⌈Further transformer specific properties can be stated inside the TransformationDescription in the role transformationDescription of a TransformationTechnology⌋

Note:
This is an abstract class without any specified content. If AUTOSAR specifies a transformer and this transformer need configuration possibilities, this class can be inherited to hold those as some kind of container.

[TPS_SYST_02040] Specification of transformer buffer handling

Upstream requirements: RS_SYST_00050

⌈The BufferProperties in the role bufferProperties of a Transformation-Technology specify the buffer handling which shall be executed by the RTE for this transformer.⌋

Class	**BufferProperties**			
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer			
Note	Configuration of the buffer properties the transformer needs to work.			
Base	*ARObject*			
Aggregated by	TransformationTechnology.bufferProperties			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
headerLength	Integer	0..1	attr	Defines the length of the header (in bits) this transformer will add in front of the data.
inPlace	Boolean	0..1	attr	If set, the transformer uses the input buffer as output buffer.

Table 7.5: BufferProperties

[constr_9279] Existence of BufferProperties.headerLength

Imposition time: IT_SysDesc

⌈For each BufferProperties, the attribute headerLength shall exist.⌋

[constr_9280] Existence of BufferProperties.inPlace

Imposition time: IT_SysDesc

⌈For each BufferProperties, the attribute inPlace shall exist.⌋

[TPS_SYST_02041] In-place buffer handling of transformers

Upstream requirements: RS_SYST_00050

⌈The attribute inPlace of BufferProperties specifies whether the transformation happens in-place.⌋

[constr_3125] Value of attribute inPlace for the first transformer in a chain

Imposition time: IT_SysDesc

⌈The attribute inPlace shall be set to false if the TransformationTechnology of the BufferProperties is referenced as first reference in the ordered list of references transformerChain from a DataTransformation.⌋

[TPS_SYST_02042] Header length to be considered by transformers

Upstream requirements: RS_SYST_00050

⌈The attribute headerLength of BufferProperties specifies the length of the header (in bits) which the transformer adds.⌋

[constr_3364] headerLength shall be a multiple of 8

Imposition time: IT_SysDesc

⌈The header length in bits specified by headerLength shall be a multiple of 8.⌋

[TPS_SYST_02044] Buffer computation of transformer

Upstream requirements: RS_SYST_00050

⌈The buffer in the RTE that is needed:

- for the SOME/IP transformation will be calculated from the length of the ISignal that is referencing a transformer chain that includes the SOME/IP Transformer.
- for the ComBased transformation will be calculated from the length of the Pdu that contains the ISignalGroup that is referencing a transformer chain that includes the ComBased Transformer.

⌋

More details can be found in the RTE specification [40]. Please note that the buffer computation for custom transformers is not formalized.

The following examples are showing the calculation of the length of an ISignal that transports a VariableDataPrototype of ImplementationDataType of category STRUCTURE via a SOME/IP Transformer.

The example struct consists of five members:

Member1: UINT16

Member2: Struct with a UINT16 length field and a one-dimensional variableSize Array with UINT8 elements and arraySize = 8

Member3: UINT32

Member4: UINT64

Member5: Struct with a UINT16 length field and a one-dimensional variableSize Array with UINT8 elements and arraySize = 8

The SOME/IP Transformer takes the InputData and adds additional 8 bytes as header. In case of SOME/IP the signal based SOMEIPTransformationISignalProps and the DataPrototype based SOMEIPTransformationProps need to be considered as well for the calculation of the ISignal.length (see chapter 7.3.2.1 for more details). In our example the following SOMEIPTransformationProps settings are valid for the variableSize Array:

- SOMEIPTransformationProps.alignment = 64

All these settings lead to the ISignal.length of 368 bits as shown in figure Figure 7.6. A padding element is inserted after the first variable size array as described in [PRS_SOMEIP_00611]. The second variable size array is the last element in the serialized data stream and therefore no padding element is inserted afterwards. The automatic padding in SOME/IP after variable size data is described in more detail in [18].

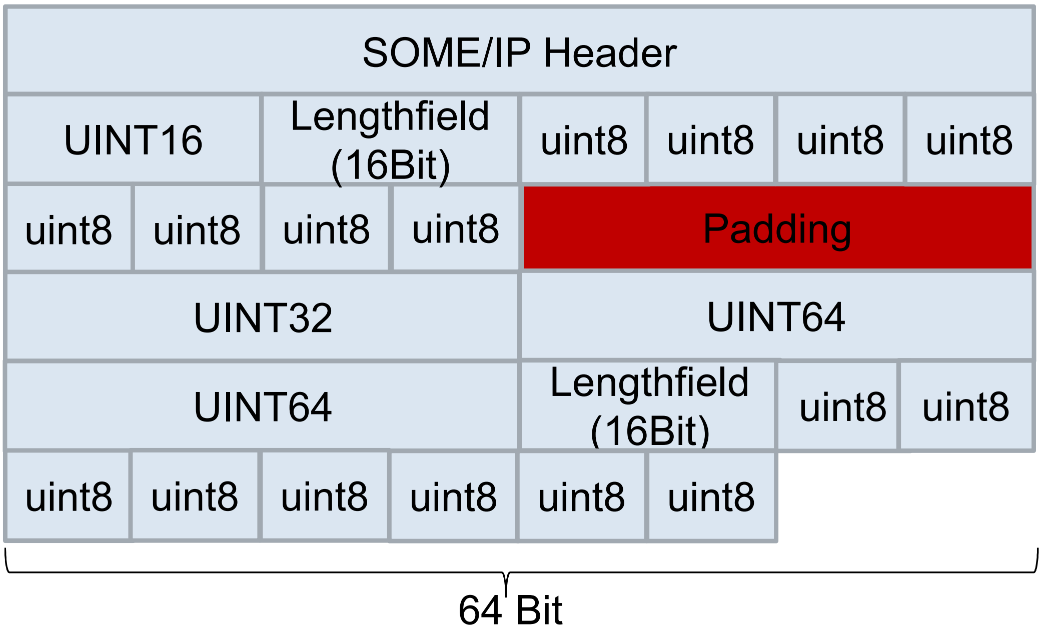

Figure 7.6: Example for calculation of the ISignal.length

Please note that the padding in the SOME/IP data stream depends on the actual number of elements that are transmitted in the variable data. Figure Figure 7.7 shows an example where only three elements are transmitted in the first variable size array and therefore the padding is restricted to 1 byte.

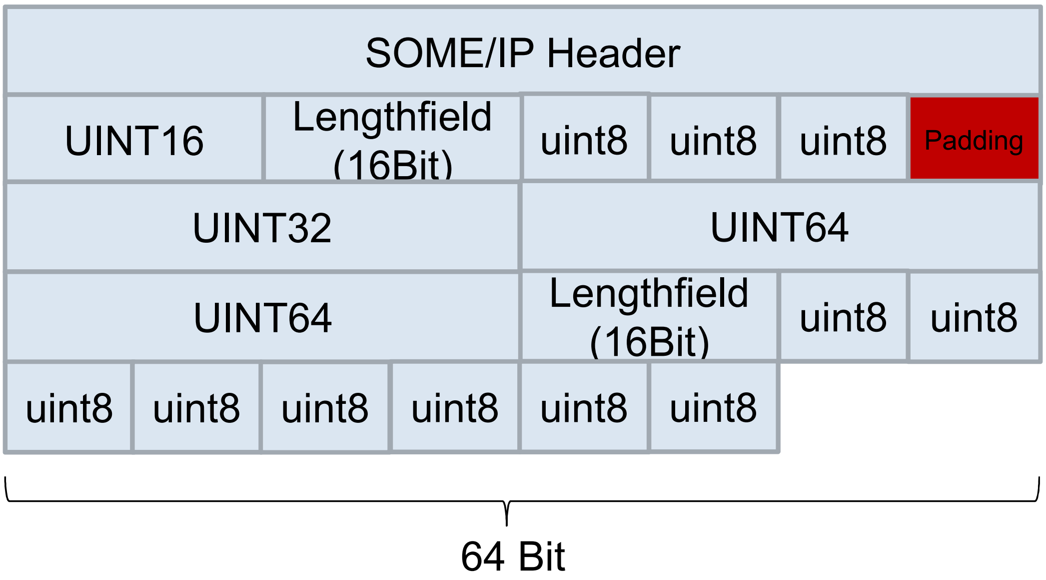

Figure 7.7: SOME/IP Padding Example

Transformer specific configuration can be done in the TransformationDescription.

[constr_5231] Allowed values for SOMEIPTransformationProps.alignment and SOMEIPTransformationDescription.alignment

Imposition time: IT_SysDesc

⌈The valid values for SOMEIPTransformationProps.alignment and SOMEIPTransformationDescription.alignment shall be 8, 16, 32, 64, 128 or 256.⌋

⌈For each `TransformationISignalProps`, the reference to `TransformationTechnology` in the role `transformer` shall exist.⌋

[TPS_SYST_02048] `ISignal` specific transformation configuration

Upstream requirements: RS_SYST_00050

⌈If an `ISignal` references a `TransformationTechnology` in the role `dataTransformation` and this transformation shall be configured `ISignal` specific, the `ISignal` shall aggregate a `TransformationISignalProps` element.⌋

[TPS_SYST_02049] Transformer specific TransformationISignalProps

Upstream requirements: RS_SYST_00050

⌈The attribute transformer of TransformationISignalProps shall reference the TransformationTechnology in the transformer chain (DataTransformation) for which the ISignal specific configuration shall be given.⌋

[constr_3213] TransformationISignalProps.csErrorReaction setting in case that the serializer transformerClass and Client/Server communication is used

Imposition time: IT_SysDesc

⌈In TransformationISignalProps the attribute csErrorReaction shall be set if the TransformationISignalProps specifies the details for a TransformationTechnology with transformerClass equal to serializer and the ISignal that aggregates the TransformationISignalProps transports a client/server communication.⌋

[constr_3214] TransformationISignalProps.csErrorReaction setting in case that a transformerClass different from serializer is used or the Client/Server communication is not used

Imposition time: IT_SysDesc

⌈In TransformationISignalProps the attribute csErrorReaction shall not be used if the TransformationISignalProps specifies the details for a TransformationTechnology with transformerClass not equal to serializer or the ISignal that aggregates the TransformationISignalProps does not transport a client/server communication.⌋

[TPS_SYST_02074] Precedence of transformer configuration settings

Upstream requirements: RS_SYST_00050

⌈The same transformer configuration settings may exist in the TransformationDescription, TransformationISignalProps and TransformationComSpecProps elements. The following precedence is valid for such settings:

- TransformationDescription: configuration valid for several ISignals (in case the SOME/IP Transformer or Custom Transformer is used) or ISignalGroups (in case the ComBasedTransformer is used).
- TransformationISignalProps: defines the configuration options valid for a specific referenced ISignal or ISignalGroup. This settings override possible settings in the TransformationDescription.
- TransformationComSpecProps: defines the configuration settings valid for the port to which the ReceiverComSpec belongs (for more details see [4]). This settings override possible settings in the TransformationDescription and TransformationISignalProps.

⌋

[TPS_SYST_02405] TransformationISignalPropsIdent.shortName usage
⌈The TransformationISignalPropsIdent.shortName shall be provided if the splitable mechanism is used and the TransformationISignalProps are distributed over different files.⌋

[TPS_SYST_02075] Mandatory attributes in transformer configuration elements

Upstream requirements: RS_SYST_00050

⌈If a transformer configuration attribute is mandatory due to a particular constraint it means that it shall be defined in at least one of the three possible locations: TransformationDescription, TransformationISignalProps or TransformationComSpecProps.⌋

Please note that it is not required to define the complete attribute set on each of those locations. It means that it is allowed to overwrite single attributes in elements according to the precedence defined in [TPS_SYST_02074].

[TPS_SYST_02050] ISignal specific configuration of the SOME/IP Transformer

Upstream requirements: RS_SYST_00050

⌈The ISignal specific configuration of the SOME/IP Transformer shall be configured using SOMEIPTransformationISignalProps.⌋

[TPS_SYST_02051] ISignal specific configuration of the E2E Transformer

Upstream requirements: RS_SYST_00050

⌈The ISignal specific configuration of the E2E Transformer shall be configured using EndToEndTransformationISignalProps.⌋

For details how to configure those transformers ISignal specific please see chapter 7.3.2 and chapter 7.3.4.

[TPS_SYST_02052] ISignal specific configuration of custom transformers

Upstream requirements: RS_SYST_00050

⌈The ISignal specific configuration of custom transformers shall be configured using UserDefinedTransformationISignalProps.⌋

To place the custom data in UserDefinedTransformationDescription the AdminData could be used for example.

To configure which communication shall be subject to transformation is done via references from ISignals and ISignalGroups to DataTransformations. An overview is shown in figure 7.10.

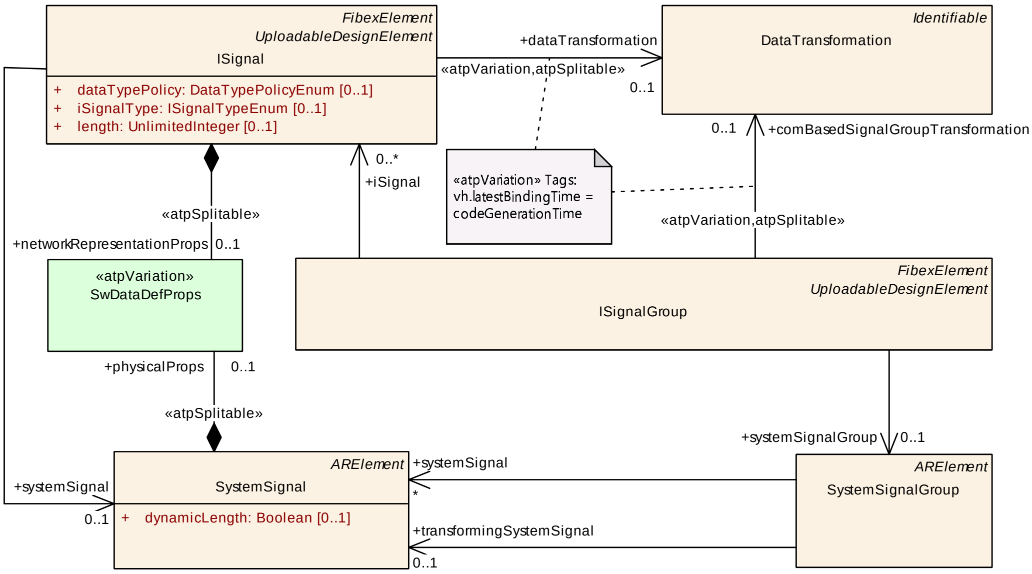

Figure 7.10: Configuration which communication shall be transformed

The DataTransformation element (which represents a transformer chain) is

- either referenced by the ISignal in the role dataTransformation which holds the transformed representation of the data
- referenced by the ISignalGroup in the role comBasedSignalGroupTransformation which holds the custom mapping of the data to the transformed representation or
- referenced by a DataPrototypeMapping in the role firstToSecondDataTransformation,

as defined in [constr_1400] in [4].

A VariableDataPrototype can either become a part of a DataPrototypeMapping based data transformation or of an ISignal-based data transformation as defined in [constr_1401] in [4].

[constr_1387] Transmission of Variable-Size Array Data Types by means of a Transformer

Imposition time: IT_SysDesc

⌈If a Transformer is used for the transmission of a Variable-Size Array Data Types then the Variable-Size Array Data Type shall be a “new-world” variable-size array data type according to [TPS_SWCT_01644] and [TPS_SWCT_01645]. “Old-world” dynamic-size array data types according to [TPS_SWCT_01641] and [TPS_SWCT_01642] are not supported.⌋

7.3.1 Generic Transformer

[TPS_SYST_02053] A reference from ISignal to DataTransformation in the role dataTransformation enables data transformation

Upstream requirements: RS_SYST_00050

⌈To enable the transformation of data, the ISignal which shall hold the transformed data shall reference a DataTransformation in the role dataTransformation.⌋

[TPS_SYST_02054] Definition of data which shall be transformed

Upstream requirements: RS_SYST_00050

⌈If

1. an ISignal references a DataTransformation and
2. this ISignal references a SystemSignal and
3. the referenced SystemSignal is referenced by a SenderReceiverToSignalMapping in the role systemSignal or referenced by a ClientServerToSignalMapping in the role returnSignal and in the role callSignal

then the VariableDataPrototype referenced by the SenderReceiverToSignalMapping or the ClientServerOperation referenced by the ClientServerToSignalMapping shall be transformed.⌋

Using this configuration the result of the transformation will be put into the ISignal even if the data type is a composite type.

Furthermore, another SystemSignal can be added to a SystemSignalGroup in the role transformingSystemSignal to support the configuration where a complex data element is transferred via Sender/Receiver communication both using transformation and traditional mapping of RTE and COM.
The ISignal which references the SystemSignal which is referenced by a SystemSignalGroup in the role transformingSystemSignal shall reference a DataTransformation to transport the transformed data.
In parallel, the traditional mapping of RTE and COM maps all other SystemSignals of the SystemSignalGroup which are referenced in the role systemSignal.

[constr_3127] Certain ISignals always need a reference to DataTransformation

Imposition time: IT_SysDesc

⌈An ISignal which references a SystemSignal which is referenced by a SystemSignalGroup in the role transformingSystemSignal shall always reference a DataTransformation.⌋

7.3.2 SOME/IP Transformer

The specific configuration for SOME/IP transformers takes place in SOMEIPTransformationDescription and SOMEIPTransformationISignalProps shown in Figure 7.11.

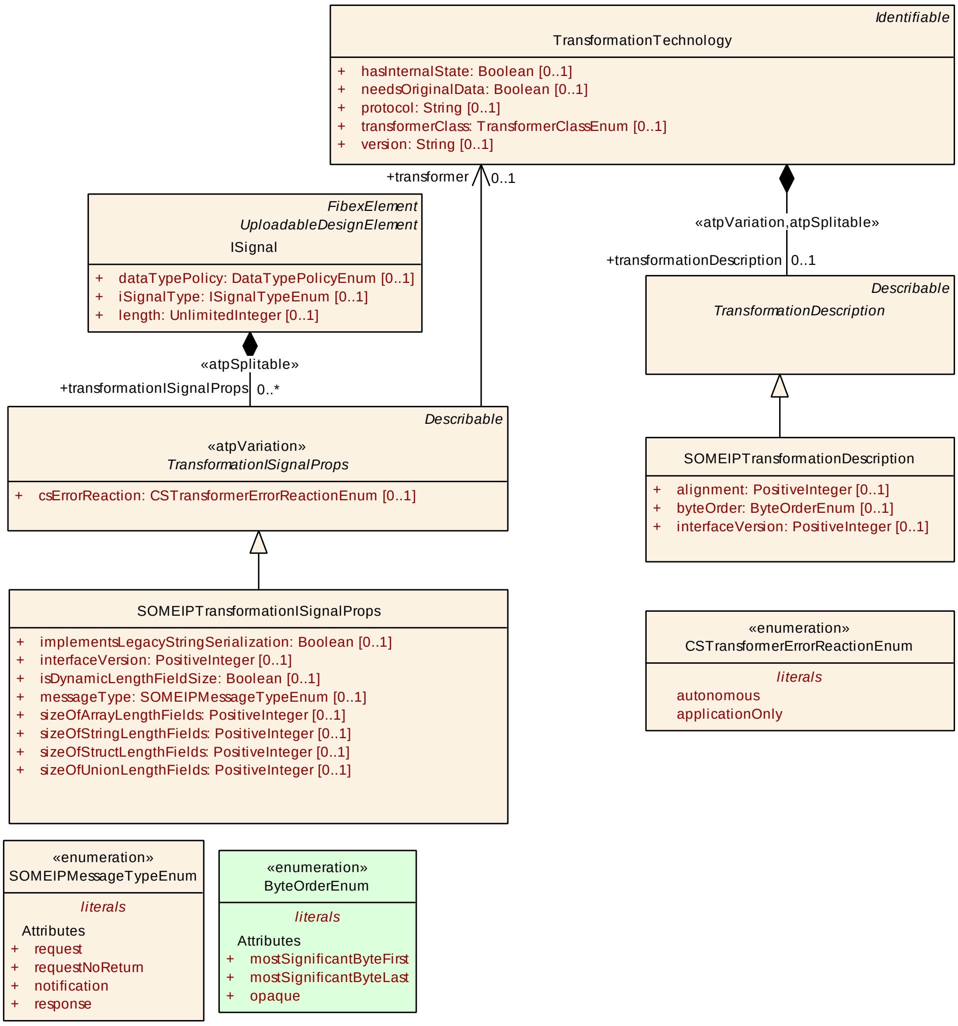

Figure 7.11: SOME/IP specific configuration

Class	**SOMEIPTransformationDescription**			
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer			
Note	The SOMEIPTransformationDescription is used to specify SOME/IP transformer specific attributes.			
Base	*ARObject*, *Describable*, *TransformationDescription*			
Aggregated by	TransformationTechnology.transformationDescription			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
alignment	PositiveInteger	0..1	attr	Defines the padding for alignment purposes that will be added by the SOME/IP transformer after the serialized data of the variable data length data element. The alignment shall be specified in Bits.

△

Class	**SOMEIPTransformationDescription**			
byteOrder	ByteOrderEnum	0..1	attr	Defines which byte order shall be serialized by the SOME/IP transformer
interfaceVersion	PositiveInteger	0..1	attr	The interface version the SOME/IP transformer shall use.

Table 7.11: SOMEIPTransformationDescription

Class	«atpVariation» **SOMEIPTransformationISignalProps**			
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer			
Note	The class SOMEIPTransformationISignalProps specifies ISignal specific configuration properties for SOME/IP transformer attributes.			
Base	*ARObject*, *Describable*, *TransformationISignalProps*			
Aggregated by	ISignal.transformationISignalProps, ISignalGroup.transformationISignalProps			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
implementsLegacyStringSerialization	Boolean	0..1	attr	This attribute indicates that Strings in the SOME/IP message shall NOT be serialized according to the SOME/IP specification for Strings. If this attribute is set to true, BOM and null-termination shall NOT be added in the serialization for Strings in the payload. If this attribute is set to false (or not set) BOM and null-termination shall be added in the serialization for Strings in the payload according to the SOME/IP specification for Strings. NOTE! This attribute is not future safe, and will be removed in an upcoming AUTOSAR release!" **Tags:** atp.Status=obsolete
interfaceVersion	PositiveInteger	0..1	attr	The interface version the SOME/IP transformer shall use.

▽

△

Class	«atpVariation» **SOMEIPTransformationISignalProps**			
isDynamic LengthFieldSize	Boolean	0..1	attr	This attribute shall be used to determine the wire type in the context of using the TLV encoding.
messageType	SOMEIPMessageType Enum	0..1	attr	The Message Type which shall be placed into the SOME/ IP header.
sizeOfArray LengthFields	PositiveInteger	0..1	attr	The size of all length fields (in Bytes) of fixed-size arrays or dynamic size arrays in the SOME/IP message. This attribute is valid for all available occurrences of fixed-size arrays or dynamic size arrays in the SOME/IP message.
sizeOfString LengthFields	PositiveInteger	0..1	attr	The size of all length fields (in Bytes) of dynamic length strings in the SOME/IP message. This attribute is valid for all available occurrences of strings in the SOME/IP message.
sizeOfStruct LengthFields	PositiveInteger	0..1	attr	The size of all length fields (in Bytes) of structs in the SOME/IP message. This attribute is valid for all available occurrences of structures in the SOME/IP message. For a more fine granular modeling on the level of Data Prototypes the DataPrototypeTransformationProps shall be used.
sizeOfUnion LengthFields	PositiveInteger	0..1	attr	The size of all length fields (in Bytes) of unions in the SOME/IP message. This attribute is valid for all available occurrences of Unions in the SOME/IP message. For a more fine granular modeling on the level of Data Prototypes the DataPrototypeTransformationProps shall be used.
tlvDataId Definition	TlvDataIdDefinitionSet	*	ref	This reference identifies the TlvDataIdDefinitions relevant for the enclosing SOMEIPTransformationISignalProps

Table 7.12: SOMEIPTransformationISignalProps

Enumeration	**ByteOrderEnum**
Package	M2::AUTOSARTemplates::GenericStructure::GeneralTemplateClasses::PrimitiveTypes
Note	When more than one byte is stored in the memory the order of those bytes may differ depending on the architecture of the processing unit. If the least significant byte is stored at the lowest address, this architecture is called little endian and otherwise it is called big endian. ByteOrder is very important in case of communication between different PUs or ECUs.
Aggregated by	ApSomeipTransformationProps.byteOrder, BaseTypeDirectDefinition.byteOrder, DiagnosticCommon Props.defaultEndianness, ISignalToIPduMapping.packingByteOrder, MultiplexedIPdu.selectorField ByteOrder, PduToFrameMapping.packingByteOrder, SegmentPosition.segmentByteOrder, SOMEIP TransformationDescription.byteOrder, System.containerIPduHeaderByteOrder
Literal	***Description***
mostSignificantByte First	Most significant byte shall come at the lowest address (also known as BigEndian or as Motorola-Format) **Tags:** atp.EnumerationLiteralIndex=0
mostSignificantByte Last	Most significant byte shall come highest address (also known as LittleEndian or as Intel-Format) **Tags:** atp.EnumerationLiteralIndex=1
opaque	For opaque data endianness conversion has to be configured to Opaque. See AUTOSAR COM Specification for more details. **Tags:** atp.EnumerationLiteralIndex=2

Table 7.13: ByteOrderEnum

Enumeration	**SOMEIPMessageTypeEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer
Note	Depending on the style of the communication different message types shall be set in the header of a SOME/IP message.
Aggregated by	SOMEIPTransformationISignalProps.messageType
Literal	*Description*
notification	A request of a notification expecting no response. **Tags:** atp.EnumerationLiteralIndex=1
request	A request expecting a response. **Tags:** atp.EnumerationLiteralIndex=2
requestNoReturn	A fire&forget request. **Tags:** atp.EnumerationLiteralIndex=3
response	The response message. **Tags:** atp.EnumerationLiteralIndex=4

Table 7.14: SOMEIPMessageTypeEnum

[constr_3128] SOME/IP transformer configuration

Imposition time: IT_SysDesc

⌈For each TransformationDescription variant that is a SOMEIPTransformationDescription

- attribute protocol of TransformationTechnology shall be set to SOMEIP
- attribute version of TransformationTechnology shall be set to 1.0.0
- attribute transformerClass of TransformationTechnology shall be set to serializer
- attribute headerLength of BufferProperties shall be set to 64 (bits).

⌋

The SOMEIPTransformationDescription contains the configuration for the transformer which shall be applied to all transformations. ISignal specific transformer configuration (which "override" the general ones) shall be done in SOMEIPTransformationISignalProps.

[TPS_SYST_02055] Alignment of SOME/IP

Upstream requirements: RS_SYST_00050

⌈The attribute alignment defines the alignment used in the SOME/IP transformer in Bits.⌋

[TPS_SYST_02056] Byte Order of SOME/IP

Upstream requirements: RS_SYST_00050

⌈The attribute byteOrder defines the byte order used in the SOME/IP transformer for creating the on wire format.⌋

[constr_3129] Byte Order of SOME/IP transformer

Imposition time: IT_SysDesc

⌈The attribute byteOrder of SOMEIPTransformationDescription shall be different from opaque.⌋

[TPS_SYST_02057] Interface Version of SOME/IP

Upstream requirements: RS_SYST_00050

⌈The attribute interfaceVersion of SOMEIPTransformationDescription as well as interfaceVersion of SOMEIPTransformationISignalProps defines the interface version used by the SOME/IP transformer.⌋

[constr_3130] Range of Interface Version

Imposition time: IT_SysDesc

⌈The value of the attribute interfaceVersion shall be in the range $[0; 255]$⌋

[TPS_SYST_02092] Size of Array Length Fields

Upstream requirements: RS_SYST_00050

⌈The attribute sizeOfArrayLengthFields of SOMEIPTransformationISignalProps defines the size of an length field generated by the SOME/IP transformer in front of all available fixed-size arrays or dynamic size arrays in the ISignal. See also [constr_3282].⌋

[constr_5244] Value of attribute SOMEIPTransformationISignalProps.sizeOfArrayLengthFields

Imposition time: IT_SysDesc

⌈If attribute SOMEIPTransformationISignalProps.sizeOfArrayLengthFields is configured, then the value of attribute SOMEIPTransformationISignalProps.sizeOfArrayLengthFields shall be at least as high as the number of bytes required to fit the maximum result of the individual length field computation of all variable-size arrays that are transported in the SOME/IP message.

In other words, for each variable-size array contained in the SOME/IP message, the numerical value of *maximum number of elements * sizeof(data type of array element)* shall be computed which yields the maximum number of bytes required to store the individual variable-size array.

The size of the attribute SOMEIPTransformationISignalProps.sizeOfArrayLengthFields shall be set such that the highest value (or bigger) obtained from the individual computations for the contained variable-size arrays can fit into the length field. The unit of attribute SOMEIPTransformationISignalProps.sizeOfArrayLengthFields is bytes.⌋

[TPS_SYST_02093] Size of Structure Length Fields

Upstream requirements: RS_SYST_00050

⌈The attribute sizeOfStructLengthFields of SOMEIPTransformationISignalProps defines the size of an length field generated by the SOME/IP transformer in front of all available structures in the ISignal. See also [constr_3283].⌋

[TPS_SYST_02359] Size of String Length Fields

Upstream requirements: RS_SYST_00050

⌈The attribute sizeOfStringLengthFields of SOMEIPTransformationISignalProps defines the size of an length field generated by the SOME/IP transformer in front of all available strings in the ISignal. See also [constr_5246].⌋

[constr_5245] Value of attribute SOMEIPTransformationISignalProps.sizeOfStringLengthFields

Imposition time: IT_SysDesc

⌈If attribute SOMEIPTransformationISignalProps.sizeOfStringLengthFields is configured, then the value of attribute SOMEIPTransformationISignalProps.sizeOfStringLengthFields shall be at least as high as the number of bytes required to fit the maximum result of the individual length field computation of all strings that are transported in the SOME/IP message.

In other words, for each string contained in the SOME/IP message, the numerical value of *maximum number of characters in the string * maximum number of code units per character (of the used character encoding) * maximum number of bytes per code unit (of the used character encoding)* shall be computed which yields the maximum number of bytes required to store the individual string.

The size of the attribute SOMEIPTransformationISignalProps.sizeOfStringLengthFields shall be set such that the highest value (or bigger) obtained from the individual computations for the contained strings can fit into the length field. The unit of attribute SOMEIPTransformationISignalProps.sizeOfStringLengthFields is bytes.⌋

[constr_1441] In AUTOSAR, the transmission of union data types over the network is only supported by the SOME/IP Transformer

Imposition time: IT_SysDesc

⌈If an ImplementationDataType according to [TPS_SWCT_01700], i.e. of category STRUCT that encloses an ImplementationDataTypeElement of category UNION, is used to directly or (via a DataTypeMap) indirectly type an AutosarDataPrototype and the latter is mapped to a SystemSignal then the ISignal that references that SystemSignal shall aggregate SOMEIPTransformationISignalProps in the role transformationISignalProps.⌋

[TPS_SYST_02094] Size of Union Length Fields

Upstream requirements: RS_SYST_00050

⌈The attribute sizeOfUnionLengthFields of SOMEIPTransformationISignalProps defines the size of an length field generated by the SOME/IP transformer in front of all available unions in the ISignal. See also [constr_3284].⌋

In principle there is no need to define a size of the length indicator because the size can be computed from the data structure itself. However there is a use case to extend on the sender side while keeping the receiver side as it is. This means that there is the need to express the size of the length indicator because the extended data structure may reach a length that exceeds the capacity of the original computed size indicator.

[constr_3218] Range of Size of Array Length Fields

Imposition time: IT_SysDesc

⌈The value of attribute sizeOfArrayLengthFields of SOMEIPTransformationISignalProps shall be either 0, 1, 2 or 4.⌋

[constr_3220] Range of Size of Structure Length Fields

Imposition time: IT_SysDesc

⌈The value of attribute sizeOfStructLengthFields of SOMEIPTransformationISignalProps shall be either 0, 1, 2 or 4.⌋

[constr_3221] Range of Size of Union Length Fields

Imposition time: IT_SysDesc

⌈The value of attribute sizeOfUnionLengthFields of SOMEIPTransformationISignalProps shall be either 0, 1, 2 or 4.⌋

[TPS_SYST_02080] Message type of SOME/IP

Upstream requirements: RS_SYST_00050

⌈The attribute messageType of SOMEIPTransformationISignalProps defines the message type used by the SOME/IP transformer for the serialized ISignal.⌋

7.3.2.1 SOME/IP Transformation Properties on the level of DataPrototypes

The serialization of SOME/IP is based on the interface specification. For certain datatypes like structures, unions and arrays SOME/IP supports the configuration of length fields that will be put in front of the serialized data. AUTOSAR supports the configuration of such SOME/IP settings on two different levels:

- modeling on `ISignal` level that is valid for all available occurrences of a datatype in the SOME/IP message (see [TPS_SYST_02092], [TPS_SYST_02093] and [TPS_SYST_02094])
- fine granular modeling on the level of `DataPrototype`s (see [TPS_SYST_02121])

To allow such a fine granular modeling `SOMEIPTransformationProps` are defined and collected in `TransformationPropsSet`s.

Class	**TransformationPropsSet**			
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer			
Note	Collection of TransformationProps. **Tags:** atp.recommendedPackage=TransformationPropsSets

7.3.2.2 Network Representation

In order to assure that the serialization of the transported data on the sender side and its deserialization on the receiver side(s) is done correctly, system designers need to assure that the same datatypes (i.e., SwBaseTypes) are used for the serialization/deserialization on both sides. However, this agreement does not imply the use or equality of the SwBaseTypes defined by the ImplementationDataType used by the application software on the sender and (possibly multiple) receiver sides. This means that each EcuInstance, regardless if it belongs to a sender or receiver, can use one datatype for the serialization/deserialization (e.g., UInt16 in the actual SOME/IP transformer code) and another datatype in the application software (e.g., Float32 in the actual application software component code).

In order to define the commonly agreed datatypes for the serialization/deserialization of the transported data by the sender and possibly multiple receivers, AUTOSAR defines the following two approaches:

- serialization based on the network representation ([TPS_SYST_02136])
- serialization based on the ImplementationDataTypes ([TPS_SYST_02137])

[TPS_SYST_02136] Serialization based on the network representation ⌈If a network representation that defines a SwBaseType is provided for each DataPrototype typed by a primitive data type that is part of the serialized ISignal (ISignal.transformationISignalProps.dataPrototypeTransformationProps.networkRepresentationProps), these SwBaseTypes shall be used for the serialization/deserialization.⌋

[TPS_SYST_02137] Serialization based on the ImplementationDataTypes ⌈For primitive DataPrototypes that are part of the serialized ISignal where no network representation is provided (ISignal.transformationISignalProps.dataPrototypeTransformationProps.networkRepresentationProps), SwBaseType shall be provided by the ImplementationDataTypes that either types the corresponding PortPrototypes on the top level Software Composition that represents the communicating EcuInstances, or it is mapped to the ApplicationDataType that types it.⌋

[constr_3317] Assuring the same data interpretation on the sender and receiver sides in case of serialization based on the ImplementationDataTypes

Imposition time: IT_SysDesc

⌈In order to assure the same interpretation of the serialized data by the SOME/IP transformers on the sender and receiver sides in case of serialization based on either a primitive or a composite ImplementationDataType, the same SwBaseType shall be defined

- for this primitive DataPrototype or
- for each primitive DataPrototype of the leaf elements of the composite DataPrototype starting from the first element until and including the last element that is requested by the receiver,

by the ImplementationDataTypes that either types the corresponding PortPrototypes on the top level Software Composition of the communicating EcuInstances, or it is mapped to the ApplicationDataType that types it.⌋

If the serialization is based on the ImplementationDataTypes, the same data has to be transmitted on all buses, i.e., it is not possible to transmit different precision (i.e., number of bits) on different buses, as with the serialization based on the network representation on the ISignal level.

ImplementationDataTypes used by the actual application for the transported data shall be defined by the corresponding PortPrototypes on the AtomicSwComponentTypes of the communicating EcuInstances. The RTE is responsible for the possible type conversion and scaling in case of different ImplementationDataTypes used for the serialization/deserialization and in the application.

[TPS_SYST_02138] Definition of the network representation ⌈The network representation for each DataPrototype typed by a primitive data type in the serialized data shall be defined by the SwDataDefProps that is aggregated by the DataPrototypeTransformationProps in the role networkRepresentationProps.⌋

In other words: If a DataPrototype is transported in the ISignal the DataPrototypeTransformationProps can be used to assign a network representation to each primitive DataPrototype that is part of the enclosing DataPrototype.

[TPS_SYST_02139] Applicability of the SwDataDefProps attributes for the network representation of the serialized data ⌈

Attributes of SwDataDefProps	networkRepresentationProps

⌋

The following settings apply in [TPS_SYST_02139]:

D Attribute can be **defined** in the scope of this element.

N/A Attribute is **not applicable** for usage in the scope of this element.

[constr_3318] Allowed use of ISignal.networkRepresentationProps

Imposition time: IT_SysDesc

⌈If a reference from ISignal to DataTransformation in the role dataTransformation exists, this ISignal SHALL NOT aggregate SwDataDefProps in the role networkRepresentationProps.⌋

This means that aggregating SwDataDefProps by an ISignal is applicable only if this ISignal is not transformed.

[constr_3319] Existence of DataPrototypeTransformationProps.networkRepresentationProps

Imposition time: IT_SysDesc

⌈ISignal.transformationISignalProps.dataPrototypeTransformationProps.networkRepresentationProps shall either

- not exist at all or
- shall be defined for all leaf elements of the root DataPrototype transmitted in the ISignal

⌋

This means that either all leaf elements of the transformed ISignal shall have a network representation, or none.

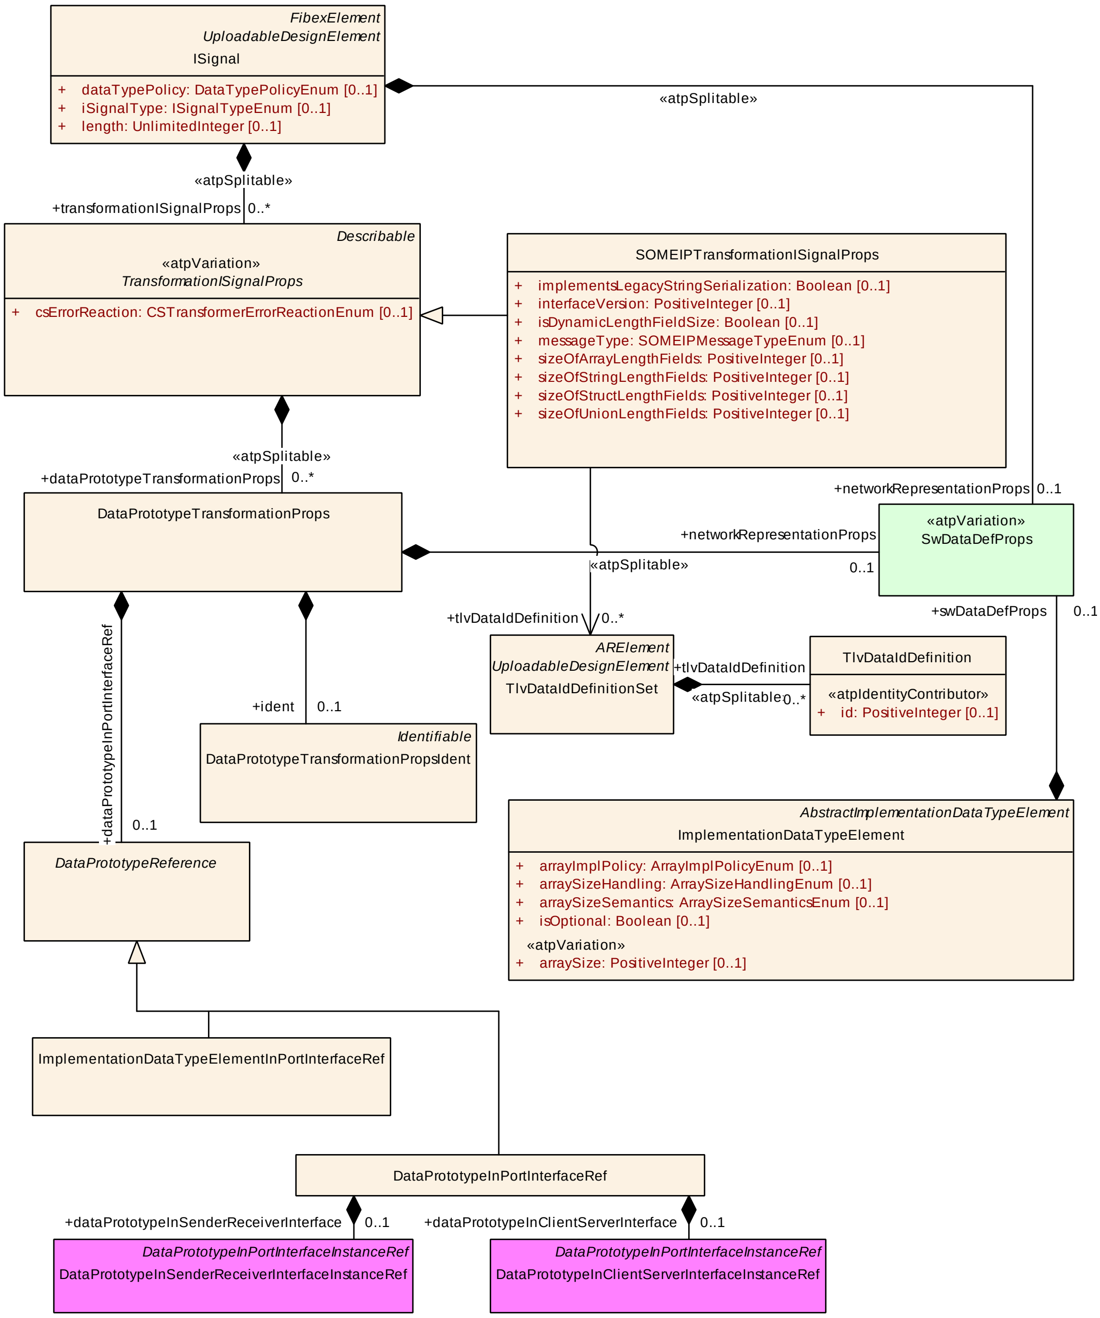

Figure 7.13: Transformer Network Representation

7.3.2.2.1 Example - Serialization based on the network representation

An example with concrete methodological steps in a common OEM-Tier 1 development process for the serialization based on the network representation is presented in Figure 7.14. The steps are as follows:

1. OEM decides on a common SwBaseType and CompuMethod for each bus, as part of the network representation, used for serialization/deserialization of one concrete complex data type.

2. OEM provides an ImplementationDataType, with SwBaseType and optional CompuMethod, on the PortPrototypes on the RootSwCompositions of the communicating EcuInstances (sender and possibly multiple receivers). The step is optional and PortPrototypes can also be typed by an ApplicationDataType that has a mapping to an ImplementationDataType.

3. Tier 1s are free to define arbitrary ImplementationDataType (with SwBaseType and optional CompuMethod) in the application software components. If this SwBaseType is different than the one used for the serialization/deserialization, RTE is responsible for the type conversion together with possible scaling defined by the CompuMethods, as part of the network representation and PortPrototypes on the RootSwComposition and SwComponentPrototype that is typed by ApplicationSwComponentType. Please note that on the receiver side it is possible that the SwComponentPrototype that is typed by ApplicationSwComponentType receives only a subset of data defined on the RootSwComposition. In this case, this needs be described by the PortInterfaceMapping.

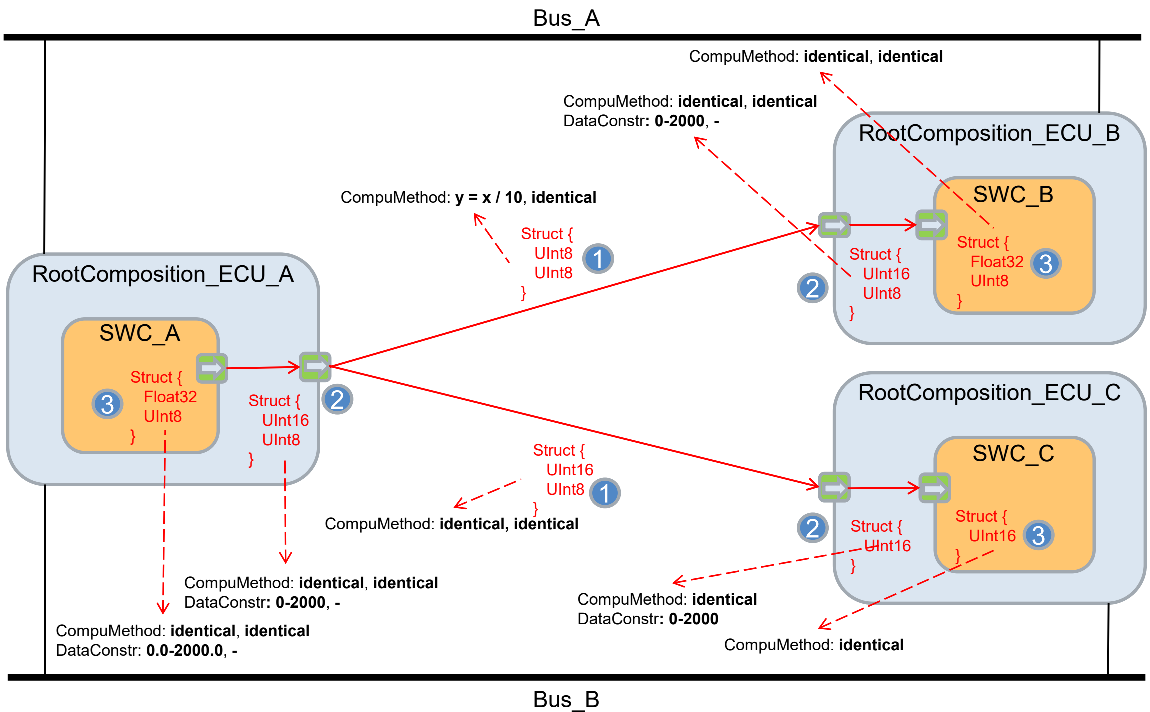

Figure 7.14: Serialization based on the network representation

The actual steps that need to be performed at runtime are presented in Figure 7.15 and they are as follows:

1. Application of the sending software component provides the data to be transmitted to the RTE and stores it in SWC internal buffer.

2. If SwBaseType defined by the ImplementationDataType on the PortPrototype of the ApplicationSwComponentType is different then the one optionally defined by the ImplementationDataType on the PortPrototype of the RootSwComposition, the RTE performs type conversion, and scaling if CompuMethods are also defined on these PortPrototypes, and stores the values internally in the RTE.

3. If network representation defines a SwBaseType that is different from the one optionally defined by the ImplementationDataType on the PortPrototype on the RootSwComposition, the RTE performs another type conversion, and scaling if CompuMethod is also defined as part of the network representation, and stores the value internally in the RTE. This internal value is used for the serialization.

4. On the receiver side, the RTE stores the serialized data in the RTE internal buffer. When the receiver SWC wants to read the data, the RTE first de-serializes the values received from the bus whose type is specified by the SwBaseType that is part of the network representation. If the SwBaseType is different then the one optionally defined by the ImplementationDataType on the PortPrototype of the RootSwComposition, the RTE performs type conversion, and scaling if CompuMethods are also defined on the PortPrototype and in the network representation, and stores the values internally in the RTE.

5. If SwBaseType defined by the ImplementationDataType on the PortPrototype of the SwComponentPrototype that is typed by ApplicationSwComponentType is different then the one defined by the ImplementationDataType on the PortPrototype of the RootSwComposition, the RTE performs another type conversion, and scaling if CompuMethods are also defined on these PortPrototype, and stores the final values internally in the buffer of the application. The RTE is also able to deliver only a subset of data to the SwComponentPrototype that is typed by ApplicationSwComponentType, if that is required by the description of the PortInterfaceMapping.

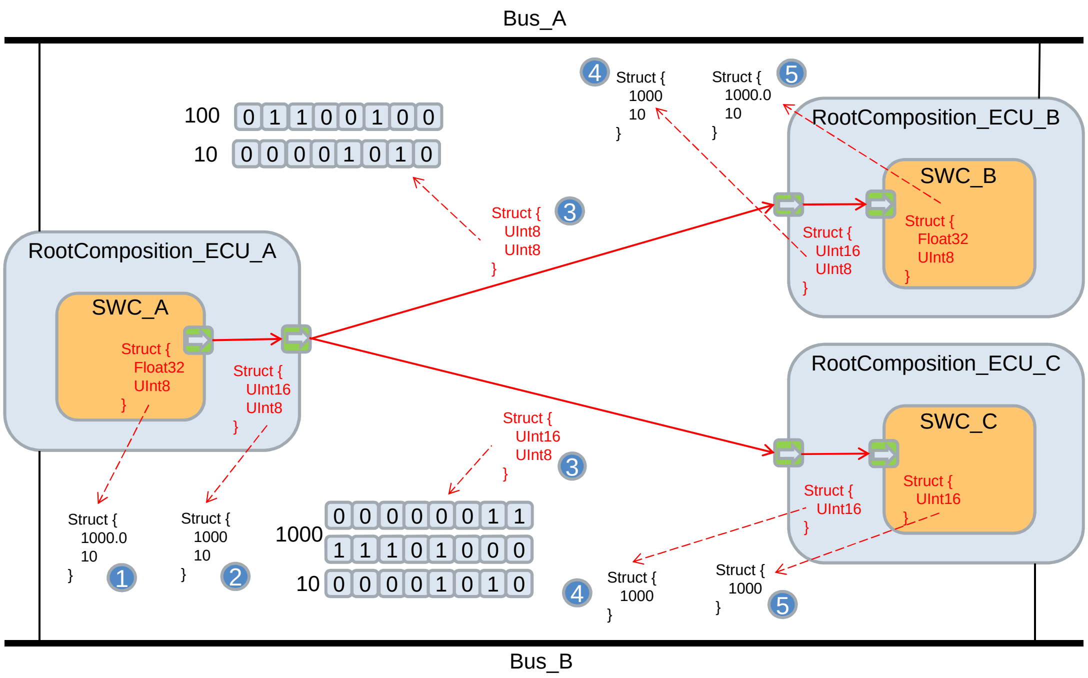

Figure 7.15: Serialization based on the network representation

7.3.2.2.1.1 Necessity of data conversion based on CompuMethods

CompuMethods are used to define how the information processed by AUTOSAR (the internal view) is to be interpreted in the physical domain. As an example the Battery-Voltage may be processed by AUTOSAR in a 1/10th scaling, thus an Integer value of 485 represents 48,5 Volt.

It is important to recognize that the value 48,5V is never handled by the AUTOSAR platform software. AUTOSAR only handles the internal representation (485).

Of course there are use-cases where the physical representation is required, e.g. monitoring tools show the measured values in the physical domain, thus have to perform a conversion. Another use-case is the dashboard where the BatteryVoltage might be displayed. But in this case it is the task of the displaying application software to perform the conversion into the physical domain, or rather into the visualization.

The AUTOSAR infrastructure (respectively the RTE) may still be required to perform a conversion of data. This is required if two CompuMethods - applying to the same data path - are not equal.

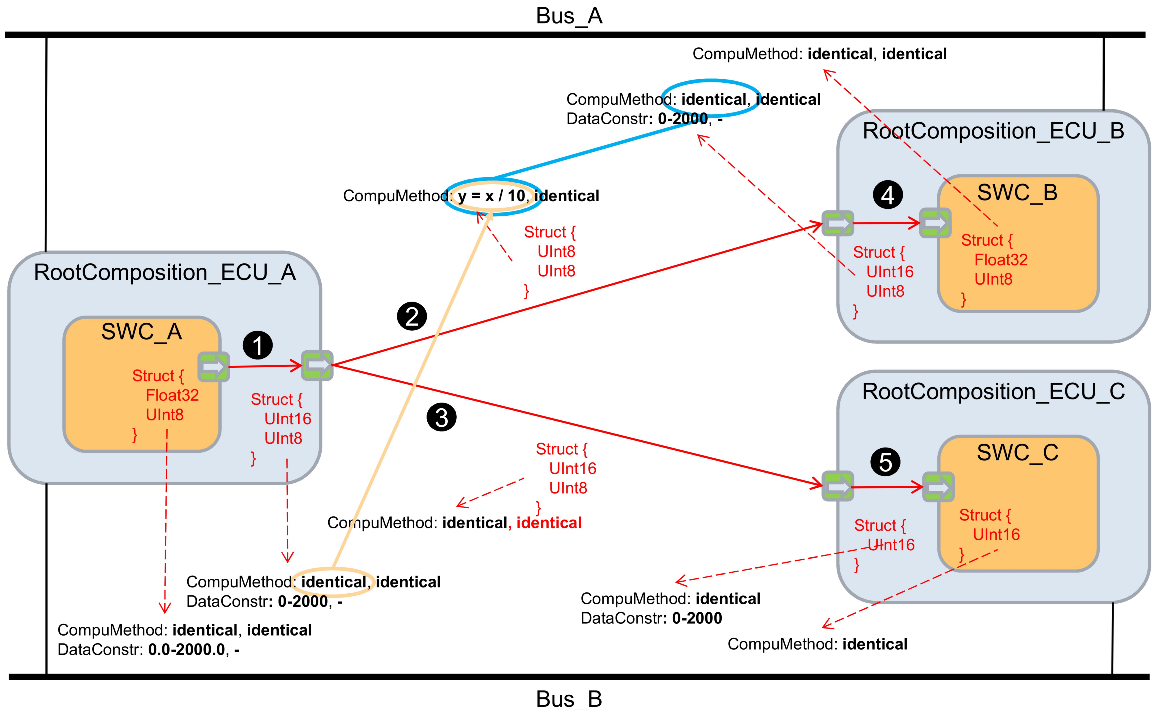

Figure 7.16: Data conversion based on CompuMethods

In the example figure 7.16 there are several CompuMethods defined for various occurrences of data: A value is produced in SWC_A with a BaseType Float32 and an "identical" CompuMethod ($y = x$). The value is then delegated to the RootComposition_ECU_A, where the BaseType is an uint16 and the CompuMethod is again "identical". For the network transport the CompuMethod is defined as $y = x/10$. As the two CompuMethods are not equal the RTE will have to convert the "identical" representation to the $y = x/10$ representation. On the reception side there is again an "identical" CompuMethod defined, thus another conversion by the receiving RTE is required.

7.3.2.2.2 Example - Serialization based on the ImplementationDataTypes

An example with concrete methodological steps in a common OEM-Tier 1 development process for the serialization based on the ImplementationDataTypes is presented in Figure 7.17. The steps are as follows:

1. OEM provides the same ImplementationDataType, with SwBaseType and optional CompuMethod, on the PortPrototypes on the RootSwCompositions of the communicating EcuInstances (sender and possibly multiple receivers). The PortPrototypes can also be typed by an ApplicationDataType that has a mapping to an ImplementationDataType.

2. Tier 1s are free to define arbitrary ImplementationDataType (with SwBaseType and optional CompuMethod) in the application software components. If this SwBaseType is different than the one used for the serialization/deserialization, RTE is responsible for the type conversion together with possible scaling defined

by the CompuMethods, as part of PortPrototypes on the RootSwComposition and AtomicSwComponentTypes. Please note that on the receiver side it is possible that the SwComponentPrototype that is typed by ApplicationSwComponentTypereceives only a subset of data defined on the RootSwComposition. In this case, this needs be described by the PortInterfaceMapping.

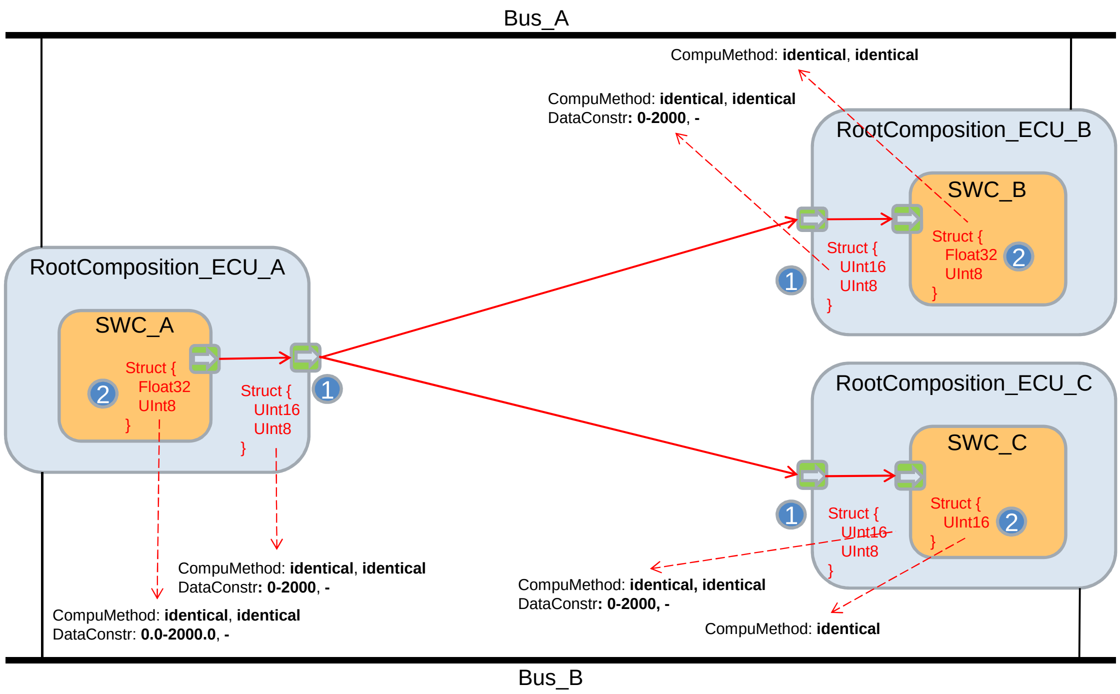

Figure 7.17: Serialization based on the ImplementationDataTypes

The actual steps that need to be performed at runtime are presented in Figure 7.18 and they are as follows:

1. Application of the sending software component provides the data to be transmitted to the RTE and stores it in SWC internal buffer.
2. If SwBaseType defined by the ImplementationDataType on the PortPrototype of the SwComponentPrototype that is typed by ApplicationSwComponentType is different then the one defined by the ImplementationDataType on the PortPrototype of the RootSwComposition, the RTE performs type conversion, and scaling if CompuMethods are also defined on these PortPrototypes, and stores the values internally in the RTE.
3. As no network representation is provided, the internal value from step 2 is used for the serialization and transmission on the bus.
4. On the receiver side, the RTE stores the serialized data received from the bus in the RTE internal buffer. When the receiver SWC wants to read the data, the RTE de-serializes these values as defined by the ImplementationDataType on the PortPrototype of the RootSwComposition.

5. If SwBaseType defined by the ImplementationDataType on the Port-Prototype of the SwComponentPrototype that is typed by Application-SwComponentType is different then the one defined by the Implementation-DataType on the PortPrototype of the RootSwComposition, the RTE performs another type conversion, and scaling if CompuMethods are also defined on these PortPrototype, and stores the final values internally in the buffer of the application. The RTE is also able to deliver only a subset of data to the SwComponentPrototype that is typed by ApplicationSwComponentType, if that is required by the description of the PortInterfaceMapping.

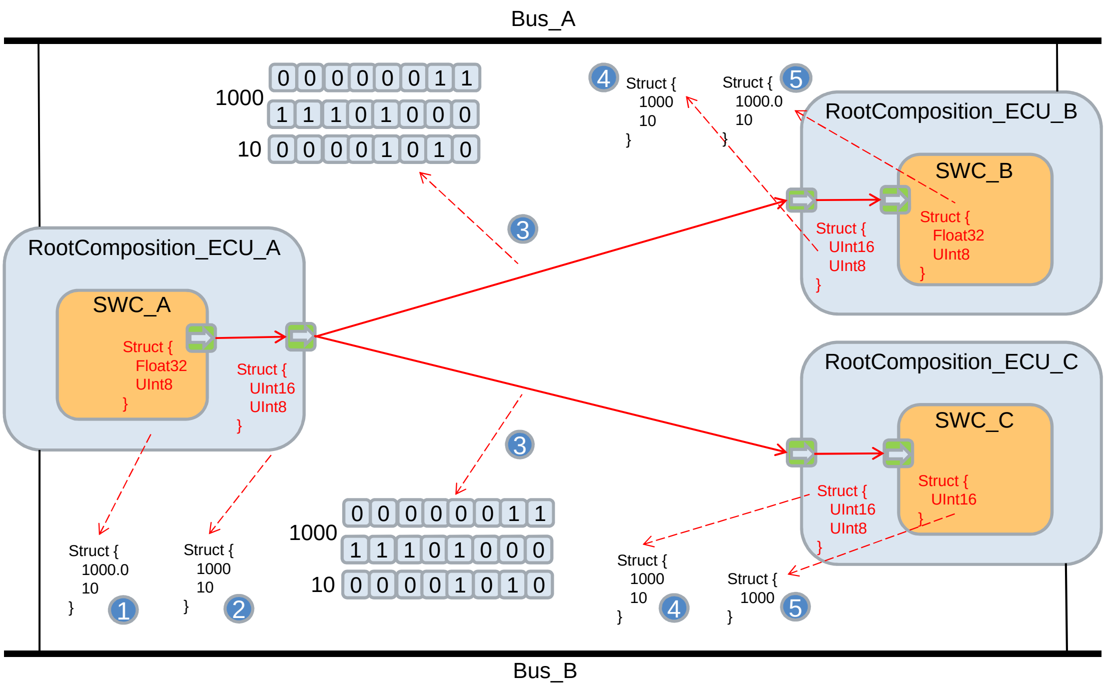

Figure 7.18: Serialization based on the ImplementationDataTypes

7.3.2.3 Less Data Than Expected Received

If an ISignal.receptionDefaultValue is provided for the case defined in [TPS_SYST_03122], then this enables the "less data than expected received" functionality of the SOME/IP serializer (see [SWS_SomeIpXf_00017]).

If an ISignal.receptionDefaultValue is provided for the case defined in [TPS_SYST_03122], then the ISignal.receptionDefaultValue shall be provided based on the SenderReceiverInterface.dataElement which is mapped (via the SenderReceiverToSignalMapping to the SystemSignal which the ISignal is referencing to in the role ISignal.systemSignal):

- NumericalValueSpecification or TextValueSpecification, if the corresponding SenderReceiverInterface.dataElement is a primitive data type

- RecordValueSpecification, if the corresponding SenderReceiverInterface.dataElement is a record data type
- ArrayValueSpecification, if the corresponding SenderReceiverInterface.dataElement is an array data type.

If the SenderReceiverInterface.dataElement is a record data type or array data type, then the leaves of that record data type and elements of the array shall be provided as NumericalValueSpecification or TextValueSpecification.

[constr_3780] ISignal.receptionDefaultValue definition in case that the SOME/IP Serializer receives less data than expected

Imposition time: IT_SysDesc

⌈If an ISignal.receptionDefaultValue is provided for the case defined in [TPS_SYST_03122], then the ISignal.receptionDefaultValue shall only be defined by

- a NumericalValueSpecification or
- a TextValueSpecification

or by

- a RecordValueSpecification or
- an ArrayValueSpecification or
- a CompositeRuleBasedValueSpecification

that (after further nesting levels consisting of RecordValueSpecification and ArrayValueSpecification are resolved) only contain

- NumericalValueSpecification
- TextValueSpecification.

⌋

The point of [constr_3780] is that the leaf elements of the ValueSpecification aggregated in the role ISignal.receptionDefaultValue shall only be NumericalValueSpecification or TextValueSpecification. In other words, it is not allowed that "application-level" ValueSpecifications are used for this role.

Some restrictions to the definition of the ISignal.receptionDefaultValue in case [TPS_SYST_03122] apply:

[TPS_SYST_03123] ISignal.receptionDefaultValue configured for SOME/IP Serializer "less data than expected received" shall only cover non-optional members ⌈For the definition of the ISignal.receptionDefaultValue in case

[TPS_SYST_03122] applies: Only non-optional members of the SenderReceiverInterface.dataElement shall be provided in the ISignal.receptionDefaultValue.⌋

[TPS_SYST_03124] ISignal.receptionDefaultValue configured for SOME/IP Serializer "less data than expected received" shall be defined in SenderReceiverInterface.dataElement order ⌈For the definition of the ISignal.receptionDefaultValue in case [TPS_SYST_03122] applies: The order of elements in ISignal.receptionDefaultValue shall follow the order as defined in the SenderReceiverInterface.dataElement.⌋

During onboard reception of actual runtime serialized messages first the SOME/IP deserializer attempts to retrieve all information from the received byte array.

If, after the deserialization has completed, there are still mandatory data elements of the SenderReceiverInterface.dataElement missing AND an ISignal.receptionDefaultValue is defined, then the SOME/IP de-serializer shall take the corresponding ISignal.receptionDefaultValue and insert it for the missing parts.

7.3.3 COM Based Transformer

In order to support the signal group based interaction of the transformer with the COM module as defined in the COM Based Transformer specification [17] a further modeling is supported:
In case the array based signal group API of Com shall be used the ISignalGroup has a reference to the DataTransformation element in the role comBasedSignalGroupTransformation. This defines that the RTE shall use the array based signal group API of Com [21] in order to transport the transformed data.

[TPS_SYST_02058] Usage of COM Based Transformer

Upstream requirements: RS_SYST_00051

⌈If

1. an ISignalGroup references a DataTransformation in the role comBasedSignalGroupTransformation and
2. this ISignalGroup references a SystemSignalGroup and
3. the referenced SystemSignalGroup is referenced by a SenderReceiverToSignalGroupMapping in the role signalGroup

then the VariableDataPrototype referenced by the SenderReceiverToSignalGroupMapping shall be transformed using the COM Based Transformer [17].⌋

[constr_5050] VariableDataPrototype of COM Based Transformer

Imposition time: IT_SysDesc

⌈The VariableDataPrototype of [TPS_SYST_02058] shall be typed by an ApplicationRecordDataType or an ImplementationDataType of category STRUCTURE.⌋

Please note that according to [SWS_Rte_03867] the RTE calculates the InputBufferLength that is used for the output buffer calculation for Sender/Receiver communication needed for the VariableDataPrototype of the dataElement of the SenderReceiverInterface that shall be transformed.

[constr_3132] Required COM Based Transformation for comBasedSignalGroupTransformation

Imposition time: IT_SysDesc

⌈If a ISignalGroup has a reference to the DataTransformation element in the role comBasedSignalGroupTransformation then this DataTransformation shall be the handled by the COM Based Transformer [17].⌋

Note that the SystemSignalGroup (and the corresponding ISignalGroup) in this case not only contains the application data element signals mapped by the SenderReceiverToSignalGroupMapping but also the data which has been added by the transformers (e.g. crc, sequence counter, ...). This is also shown in the example in Figure 7.20.

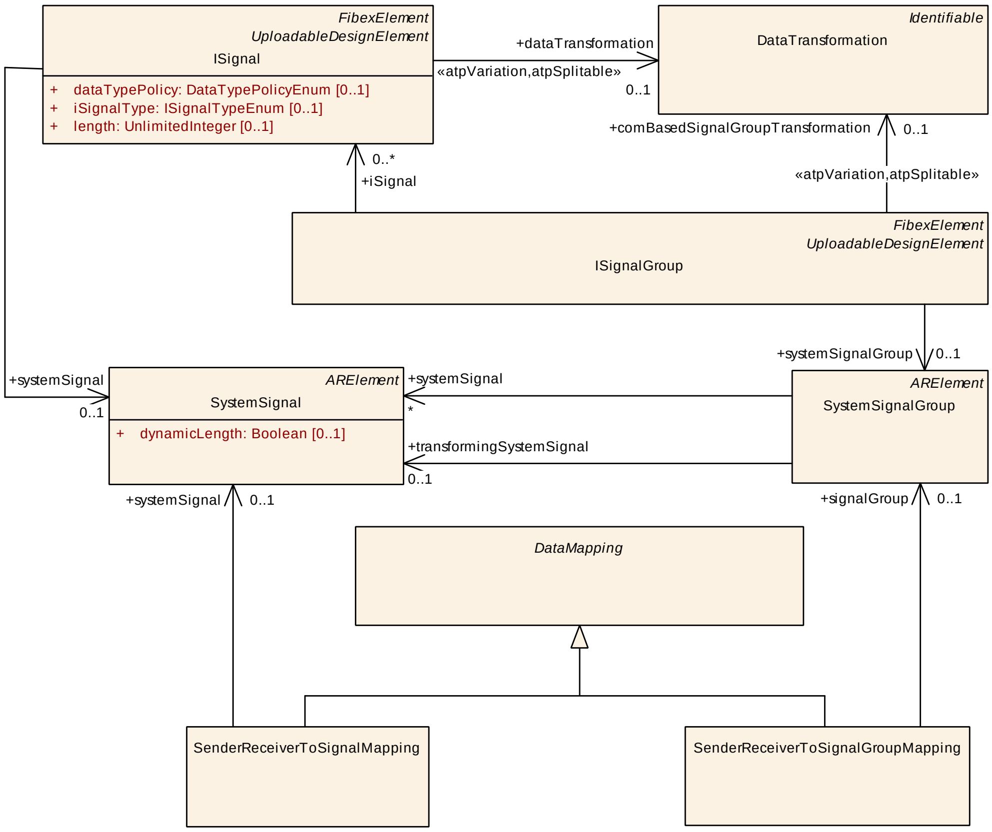

Figure 7.19: Transformer Data Mapping

[constr_3183] ISignalGroup with transformationISignalProps

Imposition time: IT_SysDesc

⌈An ISignalGroup that aggregates transformationISignalProps shall reference the DataTransformation in the role comBasedSignalGroupTransformation.⌋

[TPS_SYST_02068] Transformer header field representation in an ISignalGroup

Upstream requirements: RS_SYST_00056

⌈In case ISignalGroup has a reference to a DataTransformation in the role comBasedSignalGroupTransformation and the DataTransformation has further TransformationTechnologys defined in the role transformerChain then space for the individual headers shall be allocated by defining one ISignal per header part that is member of the ISignalGroup.⌋

[constr_3152] BufferProperties.headerLength settings for any transformer used in combination with a COM Based transformer

Imposition time: IT_SysDesc

⌈A transformer used in a transformer chain with a COM Based transformer shall be configured with the following values:

- BufferProperties.headerLength = 0

⌋

This is because the space for the transformer headers (e.g. CRC and Sequence-Counter for E2E) needs to be allocated by a proper ISignalGroup layout according to [TPS_SYST_02068].

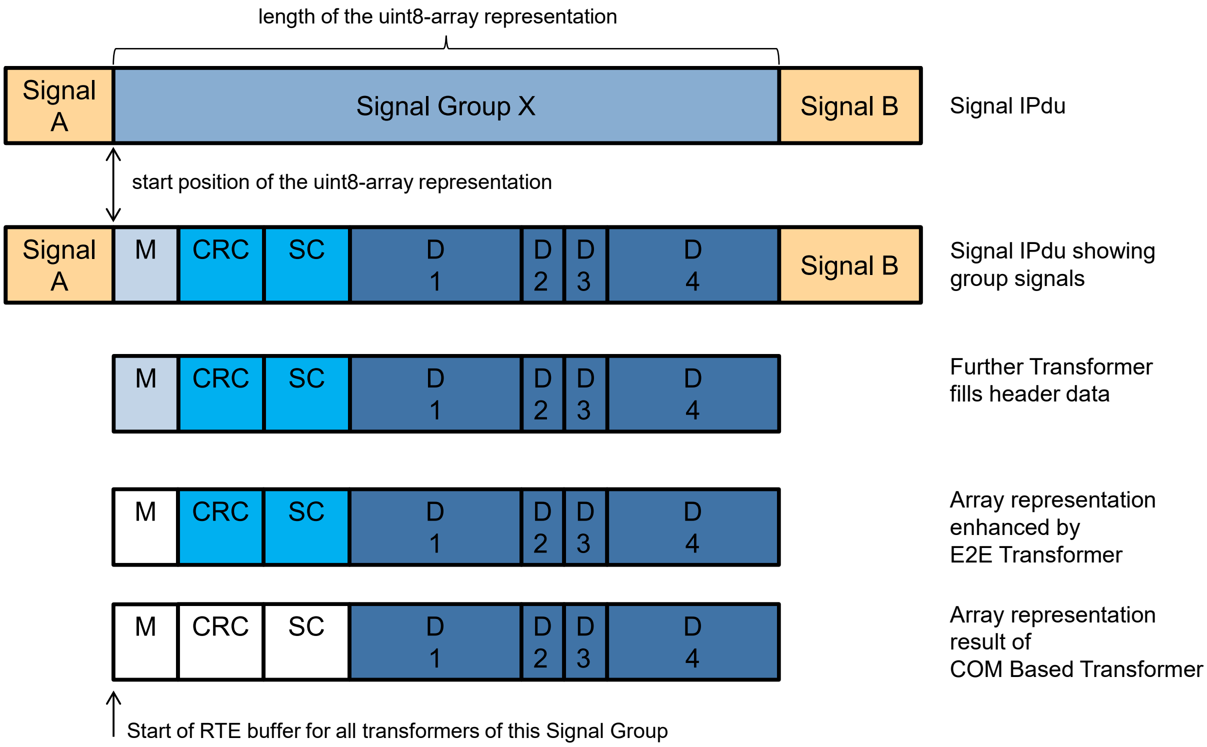

Figure 7.20: Example of COM Based Transformer buffer layout

As shown in figure 7.20 the example illustrates that for the E2E header ('CRC' and 'SC') and the 'M' header three further ISignals are defined within the ISignalGroup in order to compensate the space required by the additional transformers.

7.3.4 E2E Transformer

This section specifies the configuration of the E2E protection that is invoked "out-of-box" by RTE and realized by E2E Transformer [41], E2E Library [22] and CRC Library [42].

The specific configuration for an E2E transformer takes place in EndToEndTransformationDescription and EndToEndTransformationISignalProps shown in Figure 7.21 and in EndToEndTransformationComSpecProps (see more details in [4])

[TPS_SYST_02275] Relation between EndToEndTransformationDescription and EndToEndTransformationComSpecProps

Upstream requirements: RS_SYST_00056

⌈It is possible to overwrite the ISignal specific E2E settings that are defined in EndToEndTransformationDescription with settings available in the EndToEndTransformationComSpecProps defined at the PortPrototype of a SwComponentType. With this approach it is possible to define Port-Prototype specific configuration options for the E2E data transformer.⌋

[constr_3763] Allowed value for maxDeltaCounter in the context of a profileName

Imposition time: IT_SysDesc

⌈An EndToEndTransformationComSpecProps that is associated with an EndToEndTransformationDescription as described in [TPS_SYST_02275] shall not contain a maxDeltaCounter value that is outside the value range imposed by the profile defined in EndToEndTransformationDescription.profileName.

The profile specific value ranges are listed in [constr_3158], [constr_3195], [constr_3159], [constr_3196], [constr_3197], and [constr_3316].⌋

[constr_9331] E2E protection of a ClientServerOperation

Imposition time: IT_SysDesc

⌈If an ISignal aggregates EndToEndTransformationISignalProps and references a SystemSignal that in turn is referenced by a ClientServerToSignalMapping in the role callSignal, then the EndToEndTransformationISignalProps settings and the EndToEndTransformationDescription settings defined in the TransformationTechnology that is referenced by the EndToEndTransformationISignalProps shall have the same values for the following attributes:

- EndToEndTransformationDescription.profileName
- EndToEndTransformationDescription.offset
- EndToEndTransformationISignalProps.sourceId

as for the ISignal that is referenced by the SystemSignal that in turn is referenced by the same ClientServerToSignalMapping in the role returnSignal.⌋

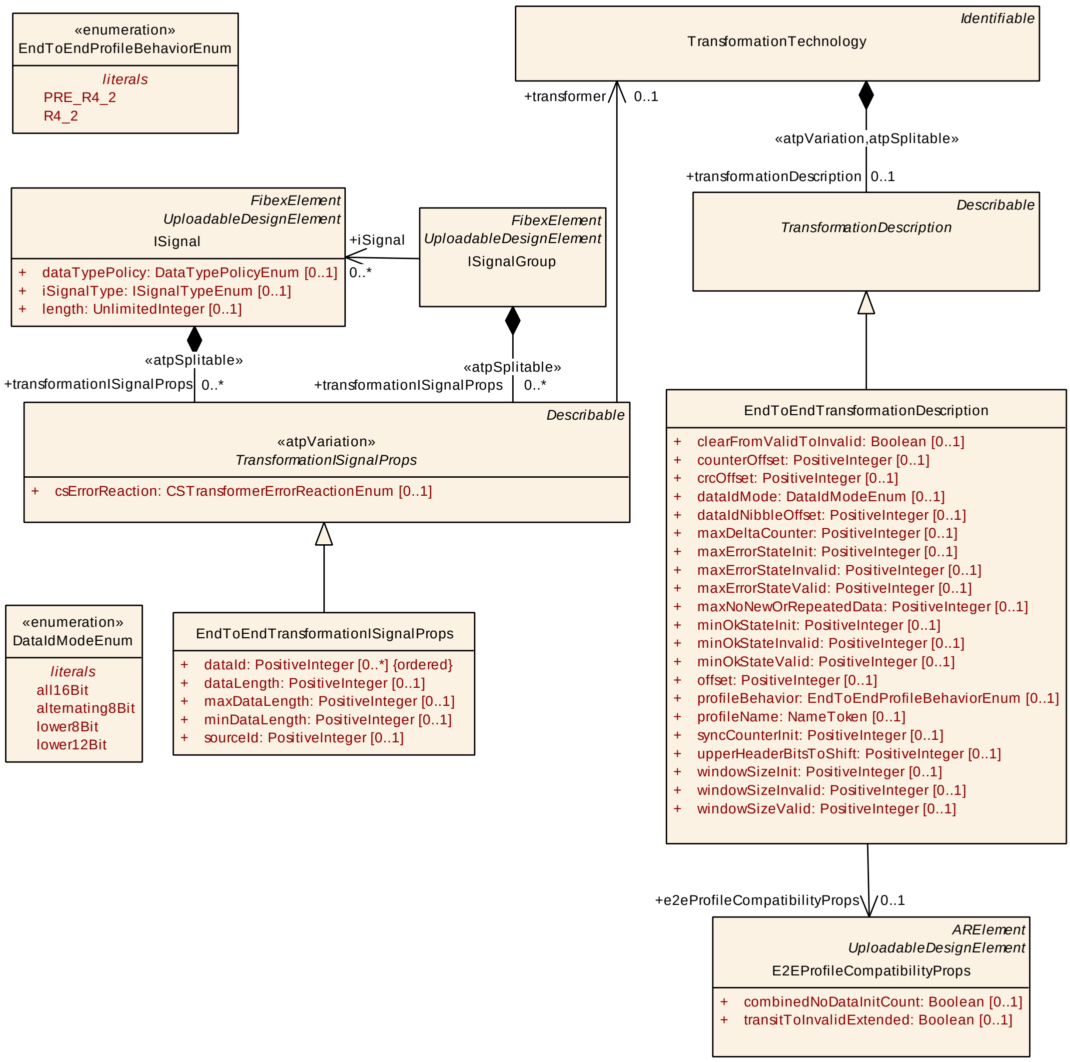

Figure 7.21: E2E Transformer Configuration

clearFromValidToInvalid	Boolean	0..1	attr	Clear monitoring window on transition from state Valid to state Invalid.
counterOffset	PositiveInteger	0..1	attr	Offset of the counter in the Data[] array in bits.
crcOffset	PositiveInteger	0..1	attr	Offset of the CRC in the Data[] array in bits.

△

Class	**EndToEndTransformationDescription**			
dataIdMode	DataIdModeEnum	0..1	attr	This attribute describes the inclusion mode that is used to include the implicit two-byte Data ID in the one-byte CRC.
dataIdNibble Offset	PositiveInteger	0..1	attr	Offset of the Data ID nibble in the Data[] array in bits.
e2eProfile Compatibility Props	E2EProfileCompatibility Props	0..1	ref	Reference to additional settings for the E2E state machine.
maxDelta Counter	PositiveInteger	0..1	attr	Maximum allowed difference between two counter values of two consecutively received valid messages. For example, if the receiver gets data with counter 1 and Max DeltaCounter is 3, then at the next reception the receiver can accept Counters with values 2, 3 or 4.
maxErrorState Init	PositiveInteger	0..1	attr	Maximal number of checks in which ProfileStatus equal to E2E_P_ERROR was determined, within the last Window Size checks, for the state E2E_SM_INIT.
maxErrorState Invalid	PositiveInteger	0..1	attr	Maximal number of checks in which ProfileStatus equal to E2E_P_ERROR was determined, within the last Window Size checks, for the state E2E_SM_INVALID.
maxErrorState Valid	PositiveInteger	0..1	attr	Maximal number of checks in which ProfileStatus equal to E2E_P_ERROR was determined, within the last Window Size checks, for the state E2E_SM_VALID.
maxNoNewOr RepeatedData	PositiveInteger	0..1	attr	The maximum allowed amount of consecutive failed counter checks.
minOkStateInit	PositiveInteger	0..1	attr	Minimal number of checks in which ProfileStatus equal to E2E_P_OK was determined, within the last WindowSize checks, for the state E2E_SM_INIT.
minOkState Invalid	PositiveInteger	0..1	attr	Minimal number of checks in which ProfileStatus equal to E2E_P_OK was determined, within the last WindowSize checks, for the state E2E_SM_INVALID.
minOkState Valid	PositiveInteger	0..1	attr	Minimal number of checks in which ProfileStatus equal to E2E_P_OK was determined, within the last WindowSize checks, for the state E2E_SM_VALID.
offset	PositiveInteger	0..1	attr	Offset of the E2E header in the Data[] array in bits.
profileBehavior	EndToEndProfile BehaviorEnum	0..1	attr	Behavior of the check functionality
profileName	NameToken	0..1	attr	Definition of the E2E profile.
syncCounterInit	PositiveInteger	0..1	attr	Number of checks required for validating the consistency of the counter that shall be received with a valid counter (i.e. counter within the allowed lock-in range) after the detection of an unexpected behavior of a received counter.

▽

△

Class	**EndToEndTransformationDescription**			
upperHeaderBitsToShift	PositiveInteger	0..1	attr	This attribute describes the number of upper-header bits to be shifted. value = 0 or not present: shift of upper header is NOT performed. value > 0: the E2E Transformer on the protect-side, takes the first upperHeaderBitsToShift bits from the upper buffer (e.g. SOME/IP header part generated by SOME/IP transformer) and shifts them towards the lower bytes and bits within the Data[] for the length of the E2E header (e.g. 12 bytes in case of E2E Profile 4). This means the shift distance is fixed - it depends on the E2E header size - what is configured here is the number of bits that are to be shifted. This option is defined because the Some/IP header generated by SOME/IP transformer shall be, due to compatibility between non-protected and E2E-protected communication, at the same position, which is before E2E header.
windowSizeInit	PositiveInteger	0..1	attr	Size of the monitoring window of state Init for the E2E state machine.
windowSizeInvalid	PositiveInteger	0..1	attr	Size of the monitoring window of state Invalid for the E2E state machine.
windowSizeValid	PositiveInteger	0..1	attr	Size of the monitoring window of state Valid for the E2E state machine.

Table 7.25: EndToEndTransformationDescription

Enumeration	**DataIdModeEnum**
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer
Note	Supported inclusion modes to include the implicit two-byte Data ID in the one-byte CRC.
Aggregated by	E2EProfileConfiguration.dataIdMode, EndToEndTransformationDescription.dataIdMode
Literal	***Description***
all16Bit	Two bytes are included in the CRC (double ID configuration). **Tags:** atp.EnumerationLiteralIndex=0
alternating8Bit	One of the two bytes byte is included, alternating high and low byte, depending on parity of the counter (alternating ID configuration). For even counter low byte is included; For odd counters the high byte is included. **Tags:** atp.EnumerationLiteralIndex=1
lower12Bit	The low byte is included in the implicit CRC calculation, the low nibble of the high byte is transmitted along with the data (i.e. it is explicitly included), the high nibble of the high byte is not used. This is applicable for the IDs up to 12 bits. **Tags:** atp.EnumerationLiteralIndex=2
lower8Bit	Only low byte is included, high byte is never used. This is applicable if the IDs in a particular system are 8 bits. **Tags:** atp.EnumerationLiteralIndex=3

Class	«atpVariation» **EndToEndTransformationISignalProps**			
dataId (ordered)	PositiveInteger	*	attr	This represents a unique numerical identifier. Note: ID is used for protection against masquerading. The details concerning the maximum number of values (this information is specific for each E2E profile) applicable for this attribute are controlled by a semantic constraint that depends on the category of the EndToEnd Protection.
dataLength	PositiveInteger	0..1	attr	Length of payload and E2E header in bits.
maxDataLength	PositiveInteger	0..1	attr	Maximum length of payload and E2E header in bits.
minDataLength	PositiveInteger	0..1	attr	Minimum length of payload and E2E header in bits.
sourceId	PositiveInteger	0..1	attr	This attribute represents a unique numerical identifier identifying the source of a certain transmission. In case of C/S communication, this ID uniquely identifies the client. Note: ID is used for protection against masquerading. The details concerning the maximum number of values (this information is specific for each E2E profile) applicable for this attribute are controlled by a semantic constraint that depends on the category of the EndToEnd Protection.

Table 7.29: EndToEndTransformationISignalProps

[constr_5229] Existence of attribute E2EProfileCompatibilityProps.transitToInvalidExtended is mandatory for each EndToEndTransformationDescription

Imposition time: IT_SysDesc

⌈For each EndToEndTransformationDescription, a reference to E2EProfileCompatibilityProps in the role e2eProfileCompatibilityProps shall exist and the referenced E2EProfileCompatibilityProps shall define a value for the attribute transitToInvalidExtended.⌋

[constr_3313] E2E transformer configuration

Imposition time: IT_SysDesc

⌈For each TransformationDescription variant that is a EndToEndTransformationDescription

- attribute protocol of TransformationTechnology shall be set to E2E
- attribute version of TransformationTechnology shall be set to 1.0.0
- attribute transformerClass of TransformationTechnology shall be set to safety

⌋

[TPS_SYST_02067] E2E profile

Upstream requirements: RS_SYST_00056

⌈The E2E profile is defined by EndToEndTransformationDescription.profileName.⌋

[constr_9287] Existence of EndToEndTransformationDescription.profileName

Imposition time: IT_SysDesc

⌈For each EndToEndTransformationDescription, the attribute profileName shall exist.⌋

[TPS_SYST_02073] EndToEndTransformationDescription.profileName

Upstream requirements: RS_SYST_00056

⌈EndToEndTransformationDescription.profileName can have the following values: PROFILE_01, PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_08m, PROFILE_11, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_44, PROFILE_44m and PROFILE_76.⌋

[TPS_SYST_02072] profileName of EndToEndTransformationDescription

Upstream requirements: RS_SYST_00056

⌈The values for the profileName of EndToEndTransformationDescription mentioned in [TPS_SYST_02073] are standardized and reserved for being used in the way the AUTOSAR standard foresees. In addition, it is positively possible to use other than the standardized values for the profileName.⌋

The setting of the EndToEndTransformationDescription.profileName has an influence on the upper- and lower multiplicities of certain attributes of EndToEndTransformationDescription and EndToEndTransformationISignalProps.

[constr_3185] Multiplicity of EndToEndTransformationDescription.dataIdMode in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to PROFILE_01 or PROFILE_11 then the multiplicity of the EndToEndTransformationDescription.dataIdMode attribute shall be 1.⌋

[constr_3186] Multiplicity of EndToEndTransformationDescription.dataIdMode in PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07,

PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to a value of PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then the multiplicity of the EndToEndTransformationDescription.dataIdMode attribute shall be 0.⌋

[constr_3326] Allowed values for EndToEndTransformationDescription.dataIdMode in PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_11 then the value of the EndToEndTransformationDescription.dataIdMode attribute shall be set to all16Bit or lower12Bit.⌋

[constr_3187] Multiplicity of EndToEndTransformationDescription.counterOffset in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to PROFILE_01 or PROFILE_11 then the multiplicity of the EndToEndTransformationDescription.counterOffset attribute shall be 1.⌋

[constr_3188] Multiplicity of EndToEndTransformationDescription.counterOffset in PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to a value of PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then the multiplicity of the EndToEndTransformationDescription.counterOffset attribute shall be 0.⌋

[constr_3189] Multiplicity of EndToEndTransformationDescription.crcOffset in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to PROFILE_01 or PROFILE_11 then the multiplicity of the EndToEndTransformationDescription.crcOffset attribute shall be 1.⌋

[constr_3190] Multiplicity of EndToEndTransformationDescription.crcOffset in PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to a value of PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then the multiplicity of the EndToEndTransformationDescription.crcOffset attribute shall be 0.⌋

[constr_3193] Multiplicity of EndToEndTransformationDescription.offset in PROFILE_01 and PROFILE_11

⌈If the EndToEndTransformationDescription.profileName attribute is set to PROFILE_01 or PROFILE_11 then the multiplicity of the EndToEndTransformationDescription.offset attribute shall be 0.⌋

[constr_3194] Multiplicity of EndToEndTransformationDescription.offset in PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to a value PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then the multiplicity of the EndToEndTransformationDescription.offset attribute shall be 1.⌋

[constr_3191] Multiplicity of EndToEndTransformationDescription.dataIdNibbleOffset in PROFILE_01, PROFILE_11 and dataIdMode equal to lower12Bit

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to PROFILE_01 or PROFILE_11 and the value of the EndToEndTransformationDescription.dataIdMode attribute is set to lower12Bit then the multiplicity of the EndToEndTransformationDescription.dataIdNibbleOffset attribute shall be 1.⌋

[constr_3192] Multiplicity of EndToEndTransformationDescription.dataIdNibbleOffset in PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m and PROFILE_76 or dataIdMode different from lower12Bit

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute is set to a value of PROFILE_02, PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 or the EndToEndTransformationDescription.dataIdMode attribute is set to value different from lower12Bit then the multiplicity of the EndToEndTransformationDescription.dataIdNibbleOffset attribute shall be 0.⌋

[constr_3148] executeDespiteDataUnavailability setting in case an E2E Transformer is used

Imposition time: IT_SysDesc

⌈A transformer chain using E2E shall be configured with DataTransformation.executeDespiteDataUnavailability = TRUE.⌋

[constr_3149] TransformationTechnology.needsOriginalData settings for E2E Transformer

Imposition time: IT_SysDesc

⌈The TransformationTechnology.needsOriginalData attribute of a TransformationTechnology element of an E2E transformer shall be set to FALSE.⌋

[constr_3151] BufferProperties.headerLength settings for an E2E transformer used in combination with a SOME/IP transformer

Imposition time: IT_SysDesc

⌈The BufferProperties.headerLength for an E2E transformer located in a transformer chain with a SOME/IP transformer shall be configured with the following values depending on the value of the EndToEndTransformationDescription.profileName attribute:

1. PROFILE_01: BufferProperties.headerLength = 16 bits
2. PROFILE_02: BufferProperties.headerLength = 16 bits
3. PROFILE_04: BufferProperties.headerLength = 96 bits
4. PROFILE_05: BufferProperties.headerLength = 24 bits
5. PROFILE_06: BufferProperties.headerLength = 40 bits
6. PROFILE_07: BufferProperties.headerLength = 160 bits

7. PROFILE_08: BufferProperties.headerLength = 128 bits
8. PROFILE_11: BufferProperties.headerLength = 16 bits
9. PROFILE_22: BufferProperties.headerLength = 16 bits
10. PROFILE_04m: BufferProperties.headerLength = 128 bits
11. PROFILE_07m: BufferProperties.headerLength = 192 bits
12. PROFILE_08m: BufferProperties.headerLength = 160 bits
13. PROFILE_44: BufferProperties.headerLength = 96 bits
14. PROFILE_44m: BufferProperties.headerLength = 128 bits

⌋

This means that the E2E header in profiles 1 and 2 use 2 bytes when using SOME/IP transformer. This yields four unused bits in case of some recommended configuration settings of Profile 1 and 2. Those unused bits are set to 0xF by the E2E transformer on the sender side.

[constr_3153] E2E header field reservation required by COM Based transformer

Imposition time: IT_SysDesc

⌈A COM Based transformer that is used in a transformer chain with an E2E transformer requires that the following amount of space is allocated for the E2E header fields using a proper ISignalGroup layout according to [TPS_SYST_02068]:

PROFILE_01: if dataIdMode == lower12Bit: 16 bits

PROFILE_01: if dataIdMode != lower12Bit: 12 bits

PROFILE_02: 16 bits

PROFILE_04: 96 bits

PROFILE_05: 24 bits

PROFILE_06: 40 bits

PROFILE_07: 160 bits

PROFILE_08: 128 bits

PROFILE_11: if dataIdMode == lower12Bit: 16 bits

PROFILE_11: if dataIdMode == all16Bit: 12 bits

PROFILE_22: 16 bits

PROFILE_04m: 128 bits

PROFILE_07m: 192 bits

PROFILE_08m: 160 bits

PROFILE_44: 96 bits

PROFILE_44m: 128 bits

PROFILE_76: 40 bits

⌋

[constr_3184] Only one EndToEndTransformationISignalProps.dataId element in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 or PROFILE_11 then the multiplicity of the EndToEndTransformationISignalProps.dataId attribute shall be 1.⌋

[constr_3156] Allowed values for EndToEndTransformationISignalProps.dataId in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 or PROFILE_11 then the value of the EndToEndTransformationISignalProps.dataId attribute shall be in the range of 0-65535.⌋

[constr_3157] Allowed values for EndToEndTransformationISignalProps.dataId in PROFILE_01 and PROFILE_11 in case dataIdMode is set to lower12Bit

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 or PROFILE_11 and the value of EndToEndTransformationDescription.dataIdMode attribute has a value of lower12Bit then the value of the EndToEndTransformationISignalProps.dataId attribute shall be in the range of 256-65535.⌋

[constr_3158] Allowed values for EndToEndTransformationDescription.maxDeltaCounter in PROFILE_01 and PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 or PROFILE_11 then the attribute maxDeltaCounter shall be in the range 1-14.⌋

[constr_3195] Allowed values for EndToEndTransformationDescription.maxDeltaCounter in PROFILE_02 and PROFILE_22

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_04, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then the multiplicity of the attribute EndToEndTransformationISignalProps.dataLength shall be 0.⌋

[constr_3533] EndToEndTransformationISignalProps.dataLength shall be a multiple of 8

Imposition time: IT_SysDesc

⌈The value of EndToEndTransformationISignalProps.dataLength, EndToEndTransformationISignalProps.maxDataLength, and EndToEndTransformationISignalProps.minDataLength shall be a multiple of 8.⌋

[constr_3155] Allowed values for EndToEndTransformationDescription.upperHeaderBitsToShift

Imposition time: IT_SysDesc

⌈The value of of the EndToEndTransformationDescription.upperHeaderBitsToShift attribute depends on the used serializing transformer:

COM based transformer: 0 (no bits are shifted)

SOME/IP transformer: 64 (to support the header shift of SOME/IP).

Custom transformer: no restriction (depends on header length and placement of custom transformer)

⌋

[constr_3165] Effect of EndToEndTransformationDescription.upperHeaderBitsToShift value in PROFILE_01, PROFILE_11

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 or PROFILE_11 and the serializing transformer is different than the ComBasedTransformer then:

1. EndToEndTransformationDescription.crcOffset shall be set to the same value of upperHeaderBitsToShift.
2. EndToEndTransformationDescription.counterOffset shall be set to the value of upperHeaderBitsToShift + 8.
3. (if used) EndToEndTransformationDescription.dataIdNibbleOffset shall be set to the value of upperHeaderBitsToShift + 12.

⌋

[constr_3327] Effect of EndToEndTransformationDescription.upperHeaderBitsToShift value in PROFILE_22

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_22 and the serializing transformer is different than the ComBasedTransformer, then EndToEndTransformationDescription.offset shall be set to the same value of upperHeaderBitsToShift.⌋

This means that the E2E header of profile 1 and profile 11, when used with SOME/IP Transformer or a Custom Transformer, is not spread across application data, but is a consecutive block of bytes. The layout flexibility available with these E2E protection profiles is therefore only supported if the ComBasedTransformer is used in combination with the E2E Transformer.

[constr_3166] EndToEndTransformationDescription.upperHeaderBitsToShift in PROFILE_02

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_02 then the value of the upperHeaderBitsToShift attribute shall be 0.⌋

[constr_3169] EndToEndTransformationDescription.offset value in PROFILE_02, PROFILE_22 and PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_02, PROFILE_22, or PROFILE_76 then the value of the EndToEndTransformationDescription.offset attribute shall be 0.⌋

[constr_3167] Effect of EndToEndTransformationDescription.upperHeaderBitsToShift value in PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m and PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 the value of the EndToEndTransformationDescription.offset attribute shall be equal to the value of the EndToEndTransformationDescription.upperHeaderBitsToShift attribute.⌋

[TPS_SYST_02194] Identification of E2E protected data in case of PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, and PROFILE_44m ⌈If the EndToEndTransformationDescription.profileName attribute has a value of PPROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44m or PROFILE_44 the E2E protected data is identified by a EndToEndTransformationISignalProps.dataId.⌋

In other words if a SystemSignal defines the E2E protected data and a fanout is described by several ISignals that point to this SystemSignal, the dataId in each of those ISignals may have the same value.

[constr_3172] Effect of EndToEndTransformationDescription.profileBehavior value in PROFILE_01

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_01 and the value of the profileBehavior attribute is R4_2 then:

- the value of the EndToEndTransformationDescription.maxNoNewOrRepeatedData attribute shall be 14.
- the value of the EndToEndTransformationDescription.syncCounterInit attribute shall be 1.

⌋

[constr_3173] Effect of EndToEndTransformationDescription.profileBehavior value in PROFILE_02

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_02 and the value of the profileBehavior attribute is R4_2 then:

- the value of the EndToEndTransformationDescription.maxNoNewOrRepeatedData attribute shall be 15.
- the value of the EndToEndTransformationDescription.syncCounterInit attribute shall be 1.

⌋

[constr_3174] EndToEndTransformationDescription settings not allowed in PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_11, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m and PROFILE_76

Imposition time: IT_SysDesc

⌈If the EndToEndTransformationDescription.profileName attribute has a value of PROFILE_04, PROFILE_05, PROFILE_06, PROFILE_07, PROFILE_08, PROFILE_11, PROFILE_22, PROFILE_04m, PROFILE_07m, PROFILE_08m, PROFILE_44, PROFILE_44m, or PROFILE_76 then:

1. the multiplicity of the EndToEndTransformationDescription.maxNoNewOrRepeatedData attribute shall be 0.
2. the multiplicity of the EndToEndTransformationDescription.syncCounterInit attribute shall be 0.
3. the multiplicity of the EndToEndTransformationDescription.profileBehavior attribute shall be 0.

⌋

The EndToEndTransformationDescription may be differently chosen for a given ISignal or ISignalGroup depending on selected variant, with the following exceptions:

[constr_3182] Restriction on TransformationTechnology.transformationDescription VariationPoint

Imposition time: IT_SysDesc

⌈The EndToEndTransformationDescription.profileName attribute shall not be subject to variability for a given ISignal / ISignalGroup, i.e., the value of the EndToEndTransformationDescription.profileName attribute shall be the same in all different variants.⌋

In other words, it is not possible that in one variant PROFILE_04 is used, and in another variant PROFILE_05 is used for the same ISignal or ISignalGroup.

7.3.4.1 E2E state machine settings

E2E state machine settings are set in EndToEndTransformationDescription and a subset of them can be overridden in EndToEndTransformationComSpecProps. The E2E state machine is described in more detail in the E2E Protocol specification [43].

Please note that the configuration of the E2E state machines with the configuration attributes available in EndToEndTransformationDescription is restricted by [PRS_E2E_CONSTR_03176], [PRS_E2E_CONSTR_03177], [PRS_E2E_CONSTR_03178], [PRS_E2E_CONSTR_03179], [PRS_E2E_CONSTR_03180], [PRS_E2E_CONSTR_03181] defined in [43].

[TPS_SYST_02419] Semantics of E2EProfileCompatibilityProps.combinedNoDataInitCount ⌈The E2EProfileCompatibilityProps.combinedNoDataInitCount defines the behavior of the E2E state machine for all E2E profiles.⌋

7.3.4.2 E2E recommended configuration settings

This chapter provides different configuration settings for particular E2E Profiles. Please note that in future additional recommended configuration settings might be added.

7.3.4.2.1 E2E Profile 1 configuration setting C

Caveat: Since the E2E wrapper approach involves technologies that are not subjected to the AUTOSAR standard and since it is superseded by the superior E2E transformer approach (which is fully standardized by AUTOSAR), support for the E2E wrapper approach will eventually be discontinued by AUTOSAR. Thus those AUTOSAR artifacts (e.g., specification items, meta classes) are to be considered as obsolete according to [TPS_STDT_00064] and will be removed from AUTOSAR with R25-11. New projects (without legacy constraints due to carry-over parts) shall use the fully standardized E2E transformer approach.

The E2E Profile 1 configuration setting C is foreseen for CAN/FlexRay messages that are serialized by the COM based transformer and should be used with RTE event-based communication, i.e. queued communication with queue size = 1, using Rte_Send / Rte_Receive.

[TPS_SYST_02069] Recommended configuration settings for E2E Profile 1 configuration setting C

Upstream requirements: RS_SYST_00056

⌈

Attribute	Allowed value	Comment
EndToEndTransformationDescription.profileName	PROFILE_01	Profile 1
EndToEndTransformationDescription.crcOffset	0	CRC offset
EndToEndTransformationDescription.counterOffset	8	Counter offset
EndToEndTransformationDescription.dataIdNibbleOffset	12	Data Id high nibble offset
EndToEndTransformationDescription.maxDeltaCounter	2	Maximum jump considered to be OK is 2, i.e. one lost message.
EndToEndTransformationDescription.minOkStateInit	1	At least one OK message
EndToEndTransformationDescription.maxErrorStateInit	1	One error allowed
EndToEndTransformationDescription.windowSizeValid	3	Last 3 messages are considered
EndToEndTransformationDescription.windowSizeInvalid	3	Last 3 messages are considered
EndToEndTransformationDescription.windowSizeInit	2	Last 2 messages are considered
EndToEndTransformationDescription.minOkStateValid	1	At least one OK message
EndToEndTransformationDescription.maxErrorStateValid	1	One error allowed
EndToEndTransformationDescription.minOkStateInvalid	2	At least two OK messages
EndToEndTransformationDescription.maxErrorStateInvalid	1	One error allowed
EndToEndTransformationDescription.upperHeaderBitsToShift	0	no bits are shifted
BufferProperties.headerLength	16	16 bits is the length of E2E profile 1C header.
EndToEndTransformationDescription.profileBehavior	R4_2	Behavior of Profile P1 adjusted for the state machine.
EndToEndTransformationDescription.maxNoNewOrRepeatedData	14	Behavior of Profile P1 adjusted for the state machine.
EndToEndTransformationDescription.syncCounterInit	1	Behavior of Profile P1 adjusted for the state machine.

⌋

7.3.4.2.2 E2E Profile 4 configuration setting A

The E2E Profile 4 configuration setting A is foreseen for long messages that are serialized by the SOME/IP transformer. The configuration setting 4A should be used with RTE event-based communication, i.e. queued communication with queue size = 1, using Rte_Send / Rte_Receive.

This configuration setting is quite strict as it does not allow any errors, i.e.:

1. Repetitions
2. Counter jumps bigger than 1.
3. Errors not related to counters (e.g. CRC, data ID, length)

As soon as any error is detected, there is a transition to invalid state.

[TPS_SYST_02070] Recommended configuration settings for E2E Profile 4 configuration setting A

Upstream requirements: RS_SYST_00056

⌈

Attribute	Allowed value	Comment
EndToEndTransformationDescription.profileName	PROFILE_04	Profile 4
EndToEndTransformationDescription.offset	64	To support the fixed location of Some/IP header
EndToEndTransformationDescription.maxDeltaCounter	1	Maximum jump considered to be OK is 1
EndToEndTransformationDescription.minOkStateInit	1	received message shall be OK.
EndToEndTransformationDescription.maxErrorStateInit	0	No errors allowed

EndToEndTransformationDescription.windowSizeInvalid	1	Only the last message is considered
EndToEndTransformationDescription.windowSizeInit	1	Only the last message is considered
EndToEndTransformationDescription.minOkStateValid	1	received message shall be OK.
EndToEndTransformationDescription.maxErrorStateValid	0	No errors allowed
EndToEndTransformationDescription.minOkStateInvalid	1	received message shall be OK.
EndToEndTransformationDescription.maxErrorStateInvalid	0	No errors allowed
EndToEndTransformationDescription.upperHeaderBitsToShift	64	64 bits from Some/IP header to be shifted
BufferProperties.headerLength	96	96 bits is the length of E2E profile 4 header.

⌋

7.3.4.2.3 E2E Profile 4 configuration setting B

The E2E Profile 4 configuration setting B is foreseen for long messages that are serialized by the SOME/IP transformer. The configuration setting 4B should be used with RTE event-based communication, i.e. queued communication with queue size = 1, using Rte_Send / Rte_Receive.

This configuration setting requires having within the monitoring window the following properties:

1. At least one OK message
2. At most one error not related to counters (e.g. CRC, data ID, length)
3. the remaining data in the monitoring window may be
    - repetitions or
    - jumps above 1.

As soon as any error is detected, there is a transition to invalid state.

[TPS_SYST_02071] Recommended configuration settings for E2E Profile 4 configuration setting B

EndToEndTransformationDescription.minOkStateValid	1	At least one OK message
EndToEndTransformationDescription.maxErrorStateValid	1	One error allowed
EndToEndTransformationDescription.minOkStateInvalid	2	At least two OK messages
EndToEndTransformationDescription.maxErrorStateInvalid	1	One error allowed
EndToEndTransformationDescription.upperHeaderBitsToShift	64	64 bits from Some/IP header to be shifted
BufferProperties.headerLength	96	96 bits is the length of E2E profile 4 header.

⌋

7.3.4.2.4 E2E Profile 5

The E2E Profile 5 configuration setting is foreseen for legacy communication and for messages that are serialized by the SOME/IP transformer. The configuration setting should be used with RTE event-based communication, i.e. queued communication with queue size = 1, using Rte_Send / Rte_Receive.

This configuration setting requires having within the monitoring window the following properties:

1. At least one OK message in a window of 2
2. At most one error not related to counters (e.g. wrong CRC, data ID, or length)
3. At most one repetition or jump above 2

The ISignal that represents the ClientServerOperation response shall refer an EndToEndTransformationDescription that defines the maxDeltaCounter for the source.

7.3.5 UserDefined Transformer

Autosar allows to describe custom Transformers that are not standardized by AUTOSAR. This is done by the usage of the following elements:

- UserDefinedTransformationDescription
- UserDefinedTransformationISignalProps
- UserDefinedTransformationProps

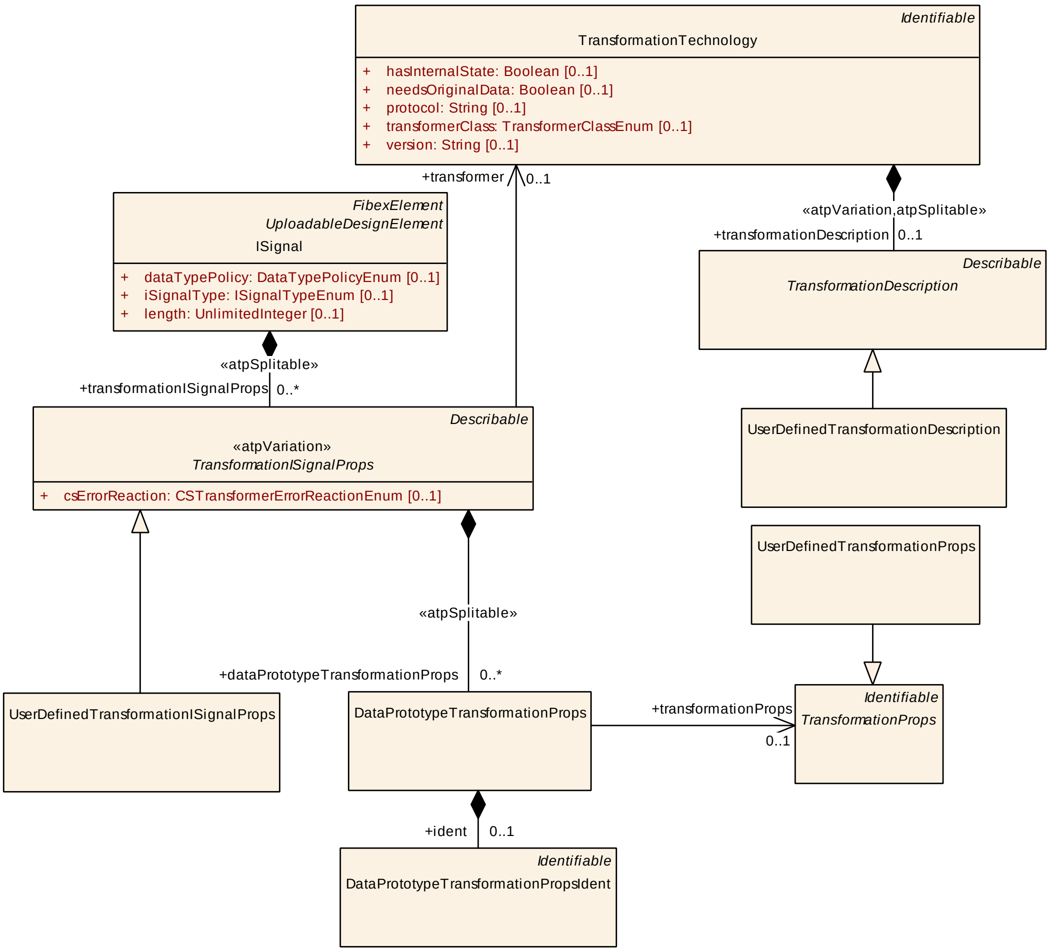

Figure 7.22: User Defined Transformation configuration

Please note that all these UserDefined classes are Identifiable or Describable and therefore are able to describe special data (sdg) which is not represented by the standard model.

7.3.6 Support for TLV Encoding

AUTOSAR supports the usage of the so-called *Tag-Length-Value* (TLV) encoding. The following sub-sections explain the details and the extent of the support for TLV encoding.

7.3.6.1 Assignment of TLV Data Ids

[TPS_SYST_05016] Assignment of TLV data ids

Upstream requirements: RS_SYST_00058

⌈The assignment of TLV data ids is done in the context of the specification of `SOMEIPTransformationISignalProps`, namely by means of the attribute `SOMEIPTransformationISignalProps.tlvDataIdDefinition.tlvDataIdDefinition.id`.⌋

This approach takes benefit from the fact that the `TlvDataIdDefinition` is able to create references to relevant model elements.

The assignment of the TLV data id is therefore done by creating such a reference and assigning a TLV data id to it by means of the attribute `TlvDataIdDefinition.id`.

Please note that the assignment of TLV data ids is compulsory for an entire data structure that has at least one optional member. In a nutshell, this conclusion (that is also backed by [PRS_SOMEIP_00230], see [18]) is the motivation for the existence of [constr_1641] and [constr_1642].

Please note further that the assignment of TLV data ids is not restricted to data structures with optional members. There is also a use case to support sending the elements of a specific data structure in arbitrary order even if none of the elements is considered optional.

Moreover, TLV data ids can also be assigned to arguments of a `ClientServerOperation`. Using TLV data ids for arguments supports that arguments can be sent in arbitrary order and that new arguments can be added at arbitrary positions during the evolution of the interface. Note that optional arguments are not supported.

[TPS_SYST_02378] Optional method arguments ⌈AUTOSAR Classic platform does not support the existence of optional method arguments.⌋

The reason for the restriction in [TPS_SYST_02378] is that the RTE does not have an API to handle optional method arguments.

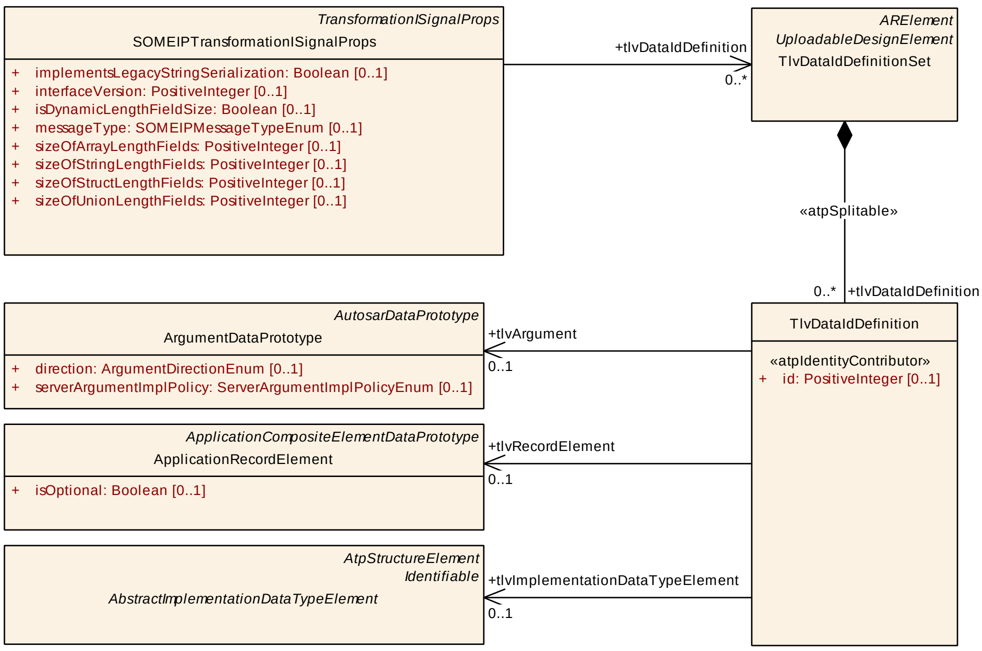

Figure 7.23: Definition of data ids for the TLV encoding inside a SOME/IP message

To sum it up: the usage of TLV data ids and optional members are two different features. Optional members require the usage of TLV data ids, but TLV data ids can also be used without having optional members.

Class	**TlvDataIdDefinitionSet**

Table 7.33: TlvDataIdDefinition

[constr_9288] Existence of `TlvDataIdDefinition.id`

Imposition time: `IT_SysDesc`

⌈For each `TlvDataIdDefinition`, the attribute `id` shall exist.⌋

[TPS_SYST_02211] Reference from `SOMEIPTransformationISignalProps` to `TlvDataIdDefinitionSet`

Upstream requirements: RS_SYST_00058

⌈The reference from `SOMEIPTransformationISignalProps` to `TlvDataIdDefinitionSet` means that it is in the hand of the creator of a model to decide whether a global scope should be assumed or whether the definition needs to be customized for a specific case.⌋

[constr_1641] Consistent assignment of TLV data ids to ApplicationRecordDataType

Imposition time: IT_SysDesc

⌈For every ApplicationRecordDataType where direct members set the attribute ApplicationRecordElement.isOptional to the value True references to all direct members of this ApplicationRecordDataType shall be created on the basis of the definition of TlvDataIdDefinition.⌋

[constr_1642] Consistent assignment of TLV data ids to ImplementationDataType or ImplementationDataTypeElement

Imposition time: IT_SysDesc

⌈For every ImplementationDataType or ImplementationDataTypeElement of category STRUCTURE where direct members set the attribute ImplementationDataTypeElement.isOptional to the value True references to all direct members of this ImplementationDataType resp ImplementationDataTypeElement shall be created on the basis of the definition of TlvDataIdDefinition.⌋

The definition of a TlvDataIdDefinition that refers to an eligible model element is not limited to scenarios where optional elements are defined. It is also possible to define TlvDataIdDefinition for arbitrary methods or data structures.

A typical use case could be to prepare the argument list or sub-elements for future extensions. However, if one argument or sub-element is referenced then it is necessary to define references from TlvDataIdDefinitions to all other arguments or sub-elements as well.

[constr_5111] Existence of references TlvDataIdDefinition.tlvArgument, TlvDataIdDefinition.tlvRecordElement, and TlvDataIdDefinition.tlvImplementationDataTypeElement

Imposition time: IT_SysDesc

⌈For each TlvDataIdDefinition, only one out of the following references shall exist:

- reference to ArgumentDataPrototype in the role tlvArgument
- reference to ApplicationRecordElement in the role tlvRecordElement
- reference to ImplementationDataTypeElement in the role tlvImplementationDataTypeElement.

⌋

[constr_1643] Completeness of the existence of a set of TlvDataIdDefinition.tlvArguments

Imposition time: IT_SysDesc

⌈If the reference TlvDataIdDefinition.tlvArguments exists for one argument of a given ClientServerOperation then further TlvDataIdDefinition.tlvArguments shall exist for all arguments of the given ClientServerOperation and all affected TlvDataIdDefinitions shall be referenced by the same SOMEIPTransformationISignalProps via TlvDataIdDefinitionSet.⌋

[constr_1644] Completeness of the existence of a set of TlvDataIdDefinition.tlvRecordElements

Imposition time: IT_SysDesc

⌈If the reference TlvDataIdDefinition.tlvRecordElement exists for one element of a given ApplicationRecordDataType then further TlvDataIdDefinition.tlvRecordElement shall exist for all elements of the given ApplicationRecordDataType and all affected TlvDataIdDefinitions shall be referenced by the same SOMEIPTransformationISignalProps via TlvDataIdDefinitionSet.⌋

[constr_1645] Completeness of the existence of a set of TlvDataIdDefinition.tlvImplementationDataTypeElements

Imposition time: IT_SysDesc

⌈Completeness of the existence of a set of TlvDataIdDefinition.tlvImplementationDataTypeElements If the reference TlvDataIdDefinition.tlvImplementationDataTypeElement exists for one subElement of a given ImplementationDataType or ImplementationDataTypeElement then further TlvDataIdDefinition.tlvImplementationDataTypeElement shall exist for all subElements of the given ImplementationDataType or ImplementationDataTypeElement and all affected TlvDataIdDefinitions shall be referenced by the same SOMEIPTransformationISignalProps via TlvDataIdDefinitionSet.⌋

The definition of a TlvDataIdDefinition.id has the purpose to provide means to unambiguously identify the argument or sub-element. For this purpose, the value of the id needs to be unique in the respective context.

[constr_1646] Scope of the uniqueness of the value of TlvDataIdDefinition.id for references to ArgumentDataPrototype

Imposition time: IT_SysDesc

⌈For all TlvDataIdDefinition that are referencing ArgumentDataPrototypes of a given ClientServerOperation in the role tlvArgument the attribute TlvDataIdDefinition.id shall exist and have a unique value in the context of respective arguments of the enclosing ClientServerOperation where attribute direction is set to the value in/inout or out/inout.

Note: an argument where attribute direction is set to the value in may have the same data id as an argument where attribute direction is set to the value out since the two are transferred in separate messages.⌋

[constr_1647] Scope of the uniqueness of the value of TlvDataIdDefinition.id for references to ApplicationRecordElement

Imposition time: IT_SysDesc

⌈For all TlvDataIdDefinition that are referencing ApplicationRecordElements of a given ApplicationDataType in the role tlvRecordElement the attribute TlvDataIdDefinition.id shall exist and have a unique value in the context of respective enclosing ApplicationRecordDataType.⌋

[constr_1648] Scope of the uniqueness of the value of TlvDataIdDefinition.id for references to ImplementationDataTypeElement

Imposition time: IT_SysDesc

⌈For all TlvDataIdDefinition that are referencing ImplementationDataTypeElements of a given ImplementationDataType/ImplementationDataTypeElement in the role tlvImplementationDataTypeElement the attribute TlvDataIdDefinition.id shall exist and have a unique value in the context of respective enclosing ImplementationDataType or ImplementationDataTypeElement.⌋

Obviously, it is necessary to avoid ambiguity with respect to the definition of TLV data ids. Each model element that can be assigned such an id shall only be assigned one id.

[constr_1649] TlvDataIdDefinition referencing ArgumentDataPrototype

Imposition time: IT_SysDesc

⌈Each ArgumentDataPrototype shall be referenced at most once in the role tlvArgument in the context of the same SOMEIPTransformationISignalProps.⌋

[constr_1650] TlvDataIdDefinition referencing ApplicationRecordElement

Imposition time: IT_SysDesc

⌈Each ApplicationRecordElement shall be referenced at most once in the role tlvRecordElement in the context of the same SOMEIPTransformationISignalProps.⌋

[constr_1651] TlvDataIdDefinition referencing ImplementationDataTypeElement

Imposition time: IT_SysDesc

⌈Each ImplementationDataTypeElement shall be referenced at most once in the role tlvImplementationDataTypeElement in the context of the same SOMEIPTransformationISignalProps.⌋

As depicted in Figure 7.23, the meta-model supports the TlvDataIdDefinition to refer both to an ApplicationRecordElement as well as an ImplementationDataTypeElement.

In a typical case either the one or the other reference will be used and there is intentionally no constraint to explicitly use both references in a concrete model.

It would mean a significant markup in real-world AUTOSAR models to explicitly require that TlvDataIdDefinitions shall exist that assign concrete ids to both a given ApplicationRecordDataType as well as the mapped ImplementationDataType.

However, scenarios are conceivable that the assignment of TLV data ids may be done based on ApplicationDataType plus networkRepresentationProps on one end of the communication and based on ImplementationDataType on the other end.

In this case, a constraint to keep TLV data ids in sync between ApplicationDataType and ImplementationDataType would not even be helpful because either side might not know about the actual data type used as the basis of the creation of the Transformer at the other end.

Nevertheless, if both an ApplicationDataType and the mapped ImplementationDataType are annotated with TLV data Ids within the same model then the associated values shall obviously be identical for corresponding sub-elements.

7.3.6.2 Assignment of TLV Wire Type

The TLV encoding supports the definition of a so-called wire type that controls how the information about the length of length fields shall be interpreted. The meaning of specific settings of the wire type is defined in [18].

[TPS_SYST_05017] Definition of the applicable wire type attribute SOMEIPTransformationISignalProps.isDynamicLengthFieldSize shall be used to define the applicable wire type

Upstream requirements: RS_SYST_00058

⌈If the value of attribute SOMEIPTransformationISignalProps.isDynamicLengthFieldSize is set to True then **wire type 5-7** shall be used.

If the value of attribute SOMEIPTransformationISignalProps.isDynamicLengthFieldSize does not exist or is set to False then **wire type 4** shall be used.⌋

[constr_1652] Definition of static length fields sizes in case of TLV usage

Imposition time: IT_SysDesc

⌈If TlvDataIdDefinitions are defined for a SOMEIPTransformationISignalProps, the attributes sizeOfArrayLengthFields, sizeOfStructLengthFields, sizeOfStringLengthFields and sizeOfUnionLengthFields shall be greater than 0.⌋

Rationale for the existence of [constr_1652]: The TLV serialization requires the usage of length fields. If wire type 4 is used the length field size shall be statically configured.

If wire types 5-7 (dynamic length field size) are used the static configuration of the length field size shall also be present since not all length fields are preceded by a tag, e.g. structures contained in an array or the top-level struct contained in a SOME/IP event. Not using length fields here would result in ambiguities.

[constr_1653] Identical values for length fields sizes in case of TLV usage

Imposition time: IT_SysDesc

⌈If TlvDataIdDefinitions are defined for a SOMEIPTransformationISignalProps, the attributes sizeOfArrayLengthFields, sizeOfStructLengthFields, sizeOfStringLengthFields and sizeOfUnionLengthFields shall have an identical value.⌋

Rationale for the existence of [constr_1653]: if an unknown member or argument is encountered the deserializer cannot determine the actual datatype of the member/argument when wire type 4 is used.

[constr_1654] No definition of length field sizes on DataPrototype level in case of TLV usage

Imposition time: IT_SysDesc

⌈If TlvDataIdDefinitions are defined for a SOMEIPTransformationISignalProps, the attributes sizeOfArrayLengthFields, sizeOfStructLengthFields and sizeOfUnionLengthFields shall not be defined on DataPrototype level but only on ISignal level.⌋

Rationale for the existence of [constr_1654]: if an unknown member or argument is encountered the deserializer needs to know the size of the length field when wire type 4 is used. The easiest way is that the size of the length field is then only defined at the top-level element.

8 Gateways

A gateway is a function within an `EcuInstance` that performs as a `FrameMapping`, `IPduMapping` or `ISignalMapping` function between two or more `CommunicationCluster`s.

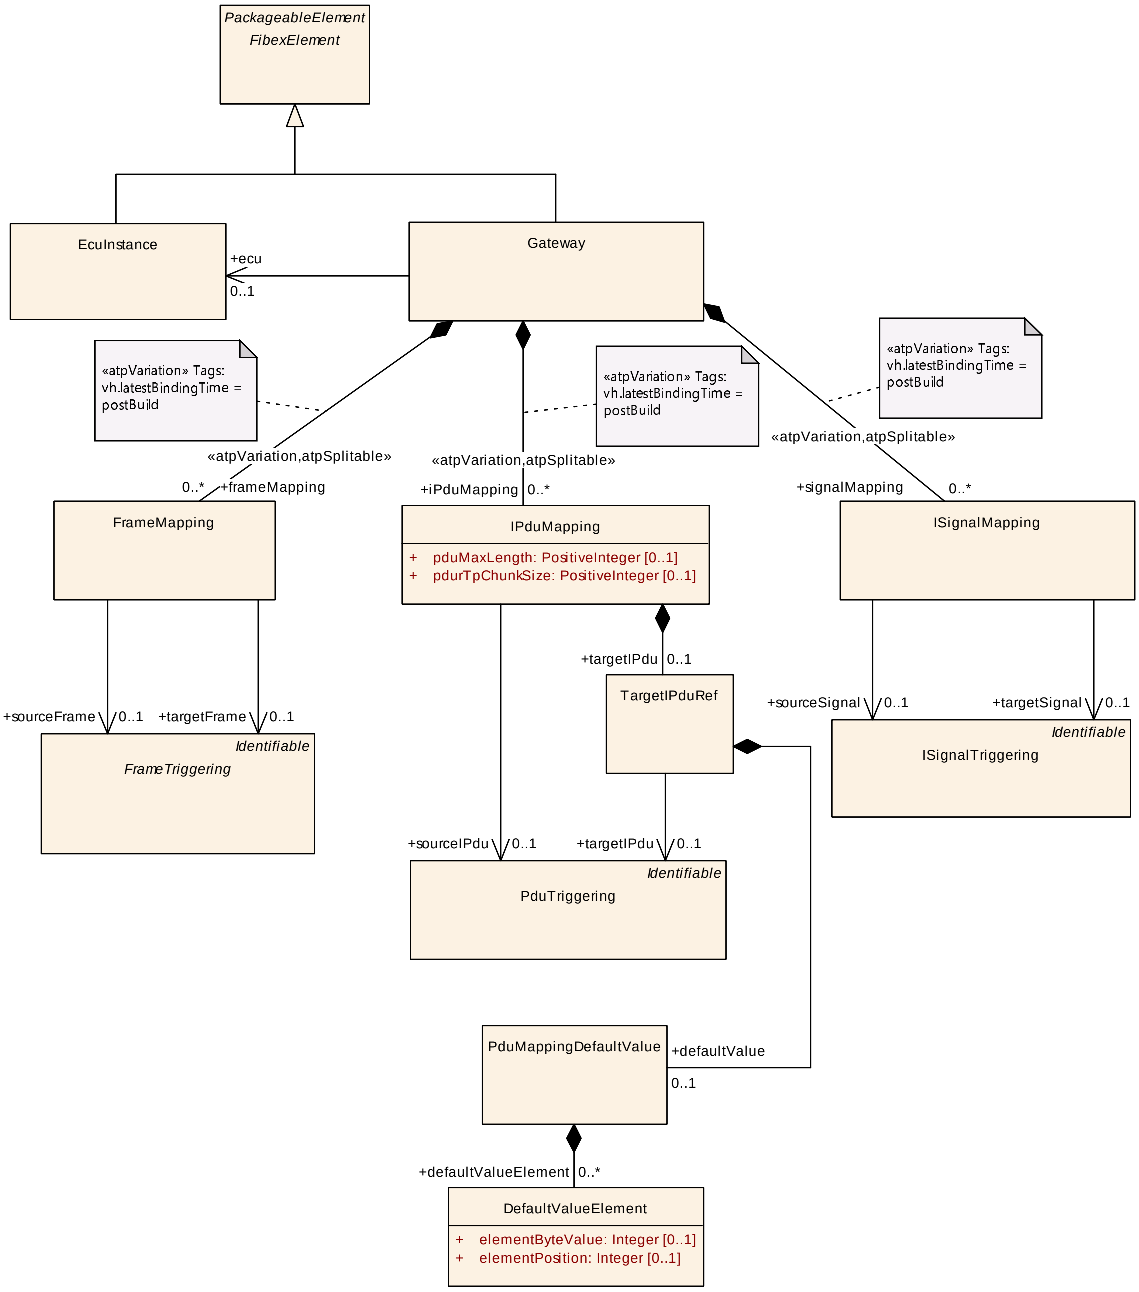

Figure 8.1: Communication Overview (Fibex4Multiplatform: Gateway)

Figure 8.1 shows the meta-model for the Gateway description in the System Template.

Class	**Gateway**			
Package	M2::AUTOSARTemplates::SystemTemplate::Fibex::Fibex4Multiplatform			
Note	A gateway is an ECU that is connected to two or more clusters (channels, but not redundant), and performs a frame, Pdu or signal mapping between them. **Tags:** atp.recommendedPackage=Gateways

8.2 IPdu Mapping

[TPS_SYST_01117] Pdu Gateway support ⌈The IPduMapping arranges those IPdus that are transferred by the Gateway from one PhysicalChannel to the other (or the same) PhysicalChannel in pairs and defines the mapping between them. Each pair consist of a sourceIPdu and a targetIPdu referencing to a PduTriggering.⌋

For FlexRay: If a Pdu is gatewayed to more than one PhysicalChannel of the same CommunicationCluster, all of this gateway relationships shall be specified. Therefore, all affected PduTriggerings shall be referenced in the gateway mappings.

[TPS_SYST_01118] Support of Multicast Pdu routing ⌈The 1:n multicast routing is supported with the definition of several IPduMappings where the sourceIPdu refers to the same PduTriggering.⌋

[TPS_SYST_02143] Support of Multisource Pdu routing ⌈The n:1 routing is supported with the definition of several IPduMappings where the targetIPdu refers to the same PduTriggering.⌋

Please note that in case of n:1 routing by a local module (e.g. COM, Dcm) it shall be enforced at run-time that *at most one* routing path is active (i.e., enabled via PduR_EnableRouting()). In case of n:1 routing by a pure gateway routing (either TP or IF) all routing paths can be active at run time.

[TPS_SYST_02207] Routing on the fly ⌈If routing on the fly is not possible in case:

- there is more than one destination routing path or
- the routing path uses the Interface (IF) API instead of Transport Protocol (TP) API

then IPduMapping.pdurTpChunkSize will be ignored in the Ecu configuration.⌋

8.2.1 Examples of IPdu Gateway configurations

In figure 8.4 an ISignalIPdu is received on a Can network: the *PduTriggeringCan* has a reference to an IPduPort for this EcuInstance with communicationDirection = in.

For illustration purposes just one ISignal is shown as part of the ISignalIPdu. This ISignal has also an ISignalTriggering defined. However, this ISignalTriggering has no reference to an ISignalPort for this EcuInstance. Therefore, there is no interaction of the payload ISignal of the ISignalIPdu defined in the scope of this EcuInstance.

The *PduTriggeringCan* is referenced by an IPduMapping in the role sourceIPdu. This defines a gateway operation where *PduTriggeringFr* is the target of the gateway (for simplicity the illustration of the TargetIPduRef has been left out). The *PduTriggeringFr* is a PduTriggering which also refers to the same ISignalIPdu as the *PduTriggeringCan*.

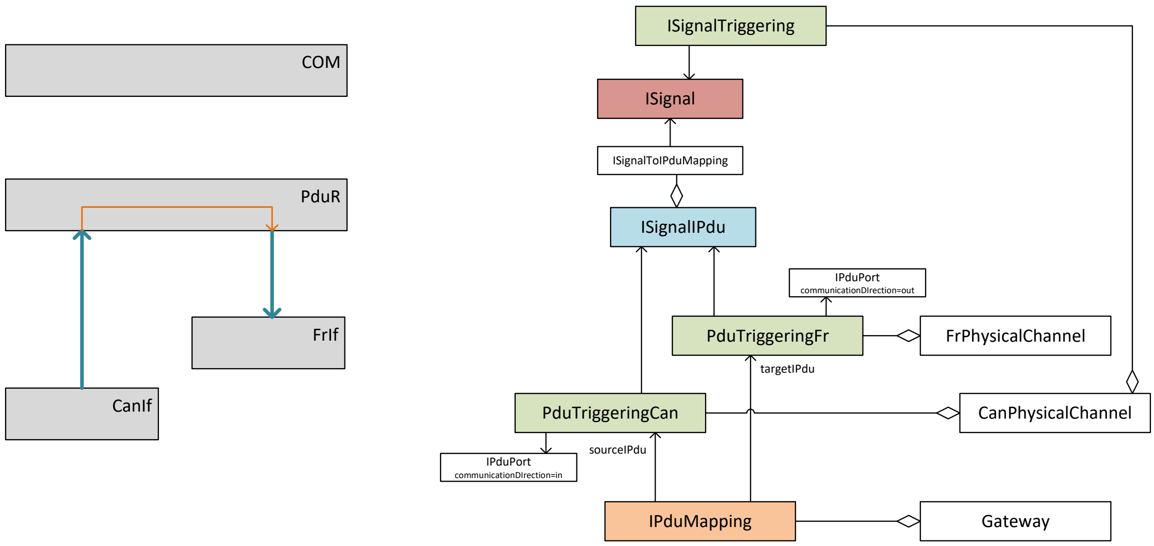

Figure 8.4: Simple IPdu Gateway definition

In figure 8.5 the same gateway operation as in figure 8.4 is defined using the `IPduMapping`. Additionally, the `ISignalTriggering` has a reference to an `ISignalPort` with `communicationDirection` = `in` for this `EcuInstance`.

The example configuration in figure 8.5 not only performs the gateway operation of the `ISignalIPdu`, but also receives the `ISignalIPdu` locally and processes the payload in the Com module. In this scenario the Pdu router module performs a "fan-out" where the received *PduTriggeringCan* (coming from the CanIf module) is forwarded to the Com module and forwarded to the FrIf module. More details on Pdu router fan-out can be found in chapter 6.11.2.1.

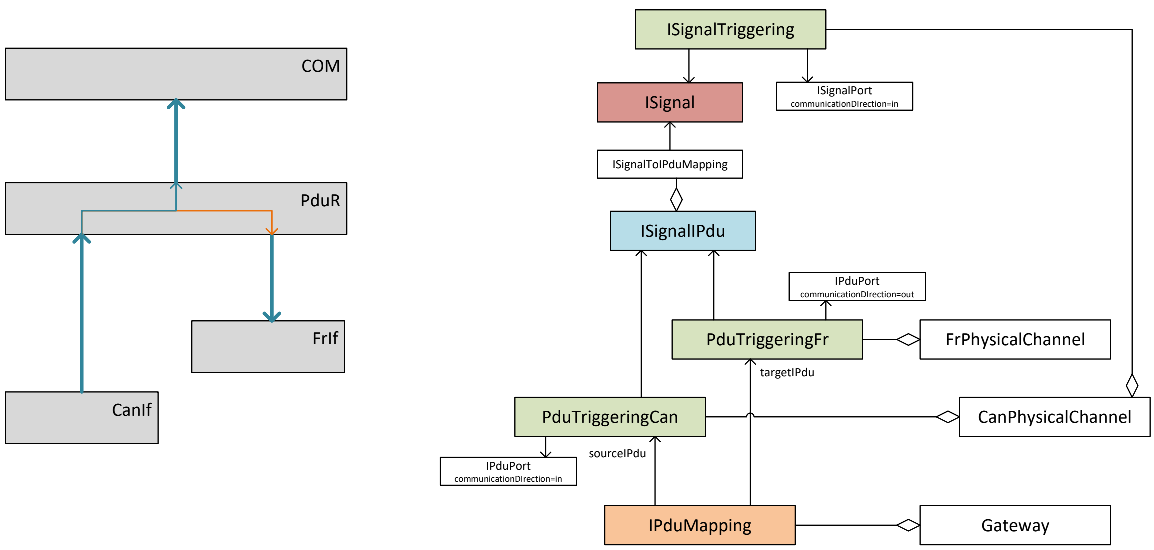

Figure 8.5: IPdu Gateway definition with local reception

One further refinement is shown in figure 8.6 where the received *PduTriggeringCan* is processed locally by the Com module and additionally defined as contained part of a ContainerIPdu. In this example the gateway operation is not immediately visible, because the received *PduTriggeringCan* is first gatewayed into the *PduTriggeringSig* which is then taken as the containedPduTriggering for the ContainerIPdu.

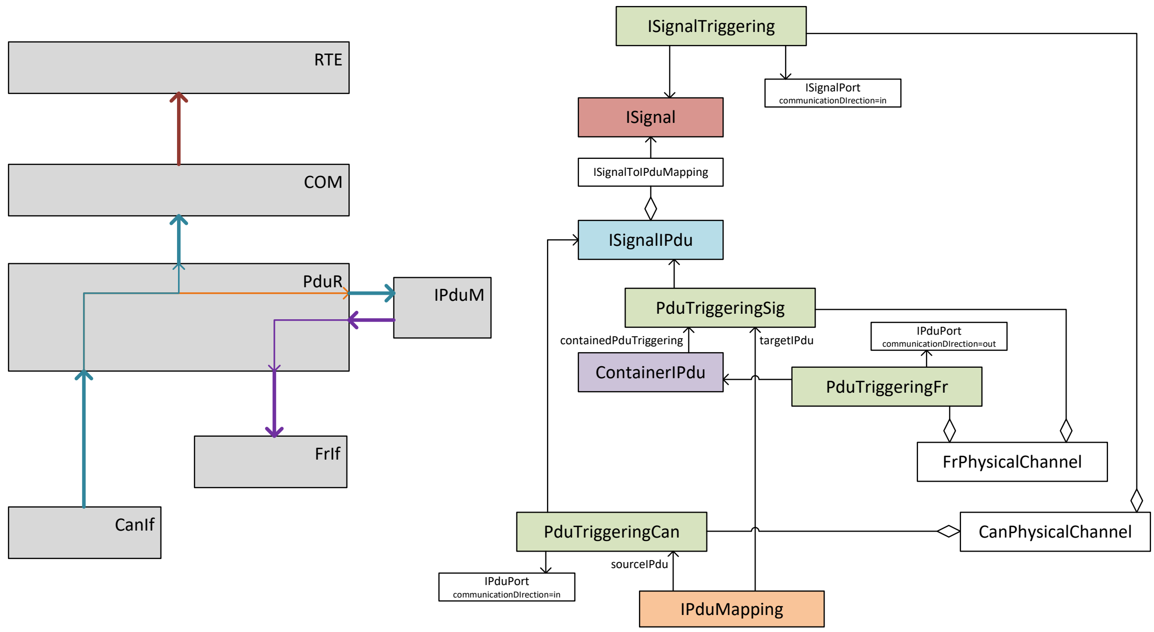

Figure 8.6: IPdu Gateway definition with local reception and container

8.2.2 Usage of IPduMapping.pduMaxLength

The Pdu gateway can be configured to use IPduMapping.pduMaxLength as a specific value per gateway operation. This value (if defined) will be used for the length configuration of the involved Pdus in the Ecu Configuration of the COM-Stack. There is no direct 1:1 correspondence of IPduMapping.pduMaxLength in EcuC, it is reflected in the value of EcuC PduLength only.

The rational for the existence of IPduMapping.pduMaxLength is that in the system template the length of a Pdu is defined at the Pdu.length attribute. The Pdu can be used in the definition of several PduTriggerings. The use-case is to have the possibility to define different ECU Configuration PduLengths for each routing operation (IPduMapping).

[TPS_SYST_02310] Pdu routing with IPduMapping.pduMaxLength ⌈The attribute IPduMapping.pduMaxLength defines a maximum length which shall be forwarded to the destination module by the PduR, if the runtime length of the actually received Pdu exceeds IPduMapping.pduMaxLength.⌋

If the attribute IPduMapping.pduMaxLength is defined the value will be derived into the EcuC PduLength configuration parameter.

- If the runtime length of the received Pdu does not exceed PduLength (now configured to the value of IPduMapping.pduMaxLength) then the PduR will forward the runtime length of the received Pdu to the corresponding targetIPdu.
- If the runtime length of the received Pdu does exceed PduLength (now configured to the value of IPduMapping.pduMaxLength) then the PduR will forward the PduLength of the received Pdu to the corresponding targetIPdu.

If the attribute IPduMapping.pduMaxLength is not defined then the Pdu.length is used to derive the PduLength configuration parameter. This corresponds to the normal routing operation.

[constr_5166] Existence of IPduMapping.pduMaxLength

Imposition time: IT_SysDesc

⌈If several IPduMappings refer to the same PduTriggering in IPduMapping.sourceIPdu, then all of these IPduMappings shall provide either no IPduMapping.pduMaxLength value, or the same IPduMapping.pduMaxLength value.⌋

[TPS_SYST_02311] IPduMapping.pduMaxLength relying on the environment length configuration ⌈IPduMapping.pduMaxLength shall not exceed the available amount of free payload bytes in the surrounding Pdus or frames of routedPdu, where routedPdu is the sourceIPdu or the targetIPdu, e.g. if routedPdu is contained in a ContainerIPdu with (ContainerIPdu.headerType = shortHeader), then IPduMapping.pduMaxLength shall not exceed (ContainerIPdu.length - 4) (4 being the byte length of the short HeaderId/Length field)⌋

Example: Pdu_A is transmitted on CAN_1 network in a CAN-FD frame and forwarded by a gateway as part of a ContainerIPdu to CAN_2 network.

Pdu_A in the transmitting ECU_A (CAN_1) has the following configuration:
Pdu.length = 9 bytes.

The routing path to route Pdu_A as Contained IPdu to CAN_2 has the following configuration:

- IPduMapping.pduMaxLength = 60 byte
- IPduMapping.sourceIPdu = PduTriggering referring to PDU_A
- IPduMapping.targetIPdu = refers to PduTriggering referring to PDU_B (PDU_B as part of a ContainerIPdu)

The length information in the system description are:

- sourceIPdu.length = 9 byte

- targetIPdu.length = 60 byte (due to pduMaxLength = 60 byte).

The gateway has no data length check configured.

Because this is an IPduMapping with pduMaxLength defined, the specific upstream mapping for the EcuC PduLength applies:

In case IPduMapping is used:
1:1 (sourceIPdu:targetIPdu) routing: When the SysTPduToPduTriggeringRef PduTriggering is referenced by an IPduMapping in the role sourceIPdu or targetIPdu, respectively, and that IPduMapping has a pduMaxLength defined then IPduMapping.pduMaxLength shall be used as PduLength for the derived PduRSrcPdu and PduRDestPdu, respectively.

The PduLength in Ecu Configuraton of the received and sent Pdu is configured to 60 byte.

Thus both, the receiving and the sending path in the gateway Ecu Configuration are prepared to handle a Pdu with 60 byte.

- ECU_A transmits PDU_A within a CAN-FD frame with a length of actually 12 byte (9 byte payload + 3 byte padding).
- ECU_B (gateway) receives the CAN-L-PDU and CanIf forwards 12 byte to the upper layer as received length.
- PduR forwards 12 byte (as the received length is smaller than IPduMapping.pduMaxLength of 60 byte)
- IpduM packs the received 12 byte payload in the container.

Update scenario: Communication matrix of ECU_A is updated and payload of PDU_A is extended to 60 Byte. ECU_B (gateway) is not updated.

- ECU_A transmits the extended PDU_A within a CAN-L-PDU with a length of 64 byte (60 byte payload + 4 byte padding).
- ECU_B (gateway) receives the CAN-L-PDU, CanIf forwards 64 byte to PduR.
- PduR forwards 60 byte (as the received length is bigger than IPduMapping.pduMaxLength of 60 byte) as received length to the IpduM.
- IPduM packs the shortened 60 byte Pdu to the configured ContainerIPdu.

[constr_5235] Maximum Frame.frameLength of the used bus protocol shall not be exceeded

Imposition time: IT_SysDesc

⌈The Pdu.length used for an IPdu and the IPduMapping.pduMaxLength used for a targetIPdu shall not exceed the limitation of the maximum Frame.frameLength of the used bus protocol (e.g. CAN2.0 max. Frame.frameLength == 8Byte, CAN-FD Frame.frameLength == 64byte).⌋

[constr_5236] Restriction of IPduMapping.pduMaxLength

Imposition time: IT_SysDesc

⌈IPduMapping.pduMaxLength shall be equal or greater than the maximum Pdu.length of sourceIPdu and targetIPdu. For a N:1 routing and 1:N routing, respectively, the maximum Pdu.length of all involved Pdus shall be used to evaluate a proper IPduMapping.pduMaxLength.⌋

8.2.3 Routing and processing of Diagnostics Pdus

An EcuInstance routes a source DcmIPdu to a destination DcmIPdu if there is an IPduMapping in place that is configured according to [TPS_SYST_01117]. The EcuInstance also processes the DcmIPdu locally if the source DcmIPdu is assigned a functional destination address.

8.3 Signal Mapping

[TPS_SYST_01119] Signal Gateway support ⌈The ISignalMapping defines the mapping between ISignals and ISignalGroups that are transferred by the Gateway from one PhysicalChannel to the other (or the same) PhysicalChannel. Each mapping pair consists of a sourceSignal and a targetSignal referencing an ISignalTriggering. Each ISignalTriggering points to either an ISignal or an ISignalGroup. The ISignal refers to the to be routed SystemSignal, the ISignalGroup refers to the to be routed SystemSignalGroup.⌋

[constr_3051] Restriction of ISignalMapping references

Imposition time: IT_SysDesc

⌈If the sourceSignal references an ISignal then the targetSignal shall also reference an ISignal.⌋

[TPS_SYST_01155] Routing of ISignalGroups ⌈If the sourceSignal references an ISignalGroup then the targetSignal can reference either an ISignalGroup or an ISignal.⌋

[constr_3052] Complete ISignalMapping of ISignalGroup signals

Imposition time: IT_SysDesc

⌈If an ISignalMapping to an ISignal that is a member of a ISignalGroup exists then (see [TPS_SYST_01120]) an ISignalMapping to the enclosing ISignalGroup shall exist as well.⌋

[TPS_SYST_02162] Routing of ISignals of ISignalGroups ⌈When performing a signal group routing two approaches are supported for the pairing of the included ISignals:

- implicit mapping: the ISignalMapping points in the sourceSignal role to an ISignalTriggering of an ISignalGroup and no ISignalMappings are defined for the included ISignals. Identical shortNames of ISignal elements identify correlating ISignals between the source and the target in the scope of the ISignalMapping.
- explicit mapping: the ISignalMapping points in the sourceSignal role to an ISignalTriggering of an ISignalGroup and in addition explicitly specified ISignalMappings define which ISignals correlate to each other.

⌋

Please note that SWS_COM [21] does not support the “implicit mapping” of [TPS_SYST_02162]. Thus it is required in the upstream mapping to derive individual ISignalMappings for all the members of a to be routed ISignalGroup.

[TPS_SYST_01120] Precedence of ISignalMappings ⌈If a dedicated ISignalMapping for at least one ISignal within an ISignalGroup exists the implicit mapping on the basis of shortNames is no longer applicable for any ISignal within that ISignalGroup.⌋

[TPS_SYST_01121] Support of Mulicast signal routing ⌈The 1:n multicast routing is supported with the definition of several ISignalMappings. See also the COM Signal Gateway fan-out description in [TPS_SYST_01110].⌋

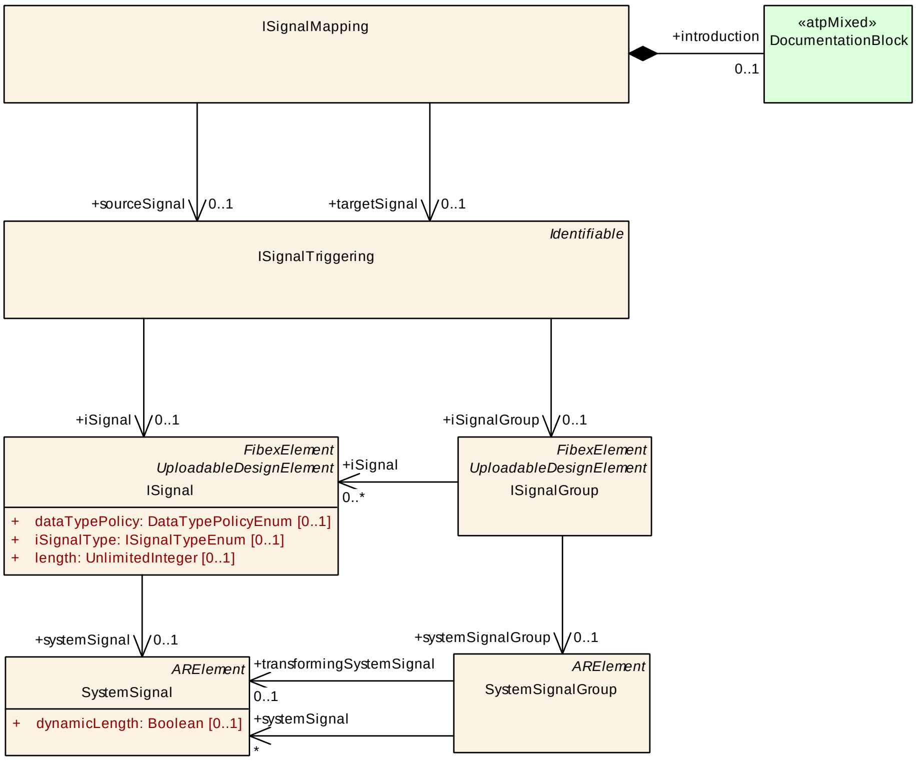

Figure 8.7: Signal Mapping (Fibex4Multiplatform: Signal Mapping)

Figure 8.8 shows an example for a partial signal group mapping with explicit mappings for the GroupSignals.

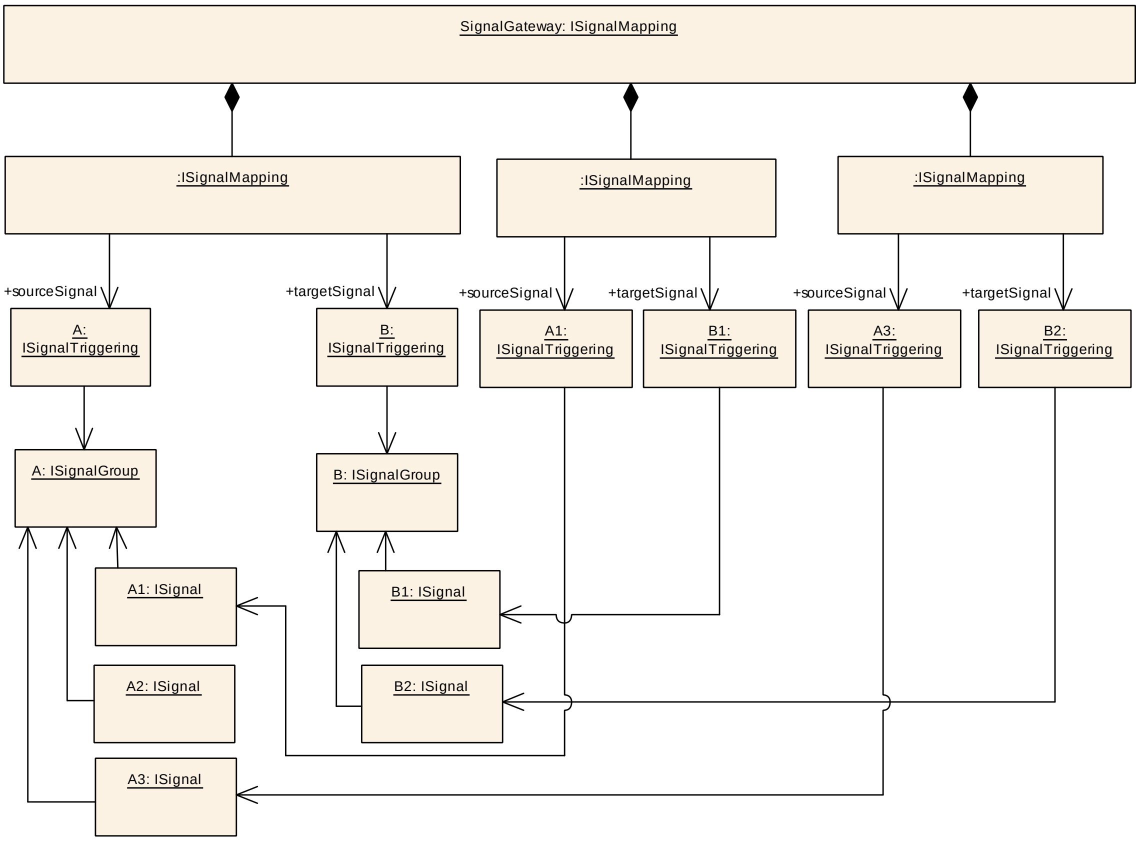

Figure 8.8: Partial Signal Group Mapping Example

9 Global Time Synchronization

9.1 Introduction

This chapter describes the modeling of how a global time synchronization in an AUTOSAR system can be achieved.

[constr_3519] Value of category of GlobalTimeDomain

Imposition time: IT_SysDesc

⌈The attribute category of GlobalTimeDomain can have the following value:

- SYNCHRONIZED: this time base does not depend on the existence of another time base

⌋

There are several use cases for implementing a system-wide global time in an vehicle:

- In case of an accident it may be necessary to post-mortem analyze whether the vehicle ECUs performed according to specification. This implies that it shall be possible to unambiguously determine the sequence of activities before a crash. This sequence can only be determined if all components in the distributed system depend on a reliable global time basis.
- It may be necessary that several ECUs in the distributed system need to act in concert with respect to the time that a specific activity is executed. A very trivial example for this requirement is the activation of turn indicators in a car. These are rarely connected to a single ECU (which could take care of synchronously flashing the turn indicators) but their synchronized execution is still very essential for the vehicle operation.
- The distribution of several global time bases shall be possible (e.g. a vehicle local time based on the runtime of the car and a GPS-based time).

It is obvious that the distribution of global time within a vehicle requires a system-wide context and therefore, the AUTOSAR System Template defines relevant meta-classes and their relations for this purpose.

Of course, the actual implementation of global time distribution is done in a couple of basic-software modules that need to be configured in the context of integrating a particular ECU. The purpose of the meta-model described in chapter 9 is to support the configuration of these basic-software modules.

The modeling of how the distribution of global time is supposed to work can roughly be distributed into two parts, the discussion of the *big picture* (see 9.2) and the description of the details that eventually will support the configuration of the corresponding basic-software modules. The latter can be found in chapter 9.3.

9.2 The big Picture

The central part of the formalization of global time synchronization is the existence of a *global time domain*, formalized as GlobalTimeDomain.

However, the fragment *global* in *global time domain* primarily stresses the fact that it is supposed to support the distribution of a *global* time rather than implying an information about the scope or visibility of a GlobalTimeDomain[1].

In other words, there is typically more than a single GlobalTimeDomain available in the System.

Please note that the concept of the GlobalTimeDomain roughly corresponds to the existence of a CommunicationCluster, i.e. it takes at least one CommunicationCluster to implement a *global time domain*.

[TPS_SYST_05006] Chaining of GlobalTimeDomains ⌈It is possible to extend the *global time domain* to several CommunicationClusters that are interconnected by means of a Gateway.

In other words, the global time base is routed from one CommunicationCluster to another, whereas the Time Slave resp. Time Slave Port updates its local time base by using the received global time base and takes into account, whether a time base correction has to be considered or not.

There are certainly use-cases for implementing a GlobalTimeDomain that extends to several CommunicationClusters, but in many (if not in the majority of) cases it will be necessary to update the time information for the sake of precision.

In this case, however, two separate GlobalTimeDomains rather than a single GlobalTimeDomain exist. The GlobalTimeDomain relate to each other such that one GlobalTimeDomain refers to the other in the role globalTimeSubDomain.⌋

In order to understand the way how GlobalTimeDomains refer to each other, it is important to understand that the concept of a *global time domain* has an underlying asymmetric approach of how the time information is distributed.

That is, not all participants in the communication of global time information are able and/or entitled to update the time information and send it around for others to consume.

The identification of a global time domain on the system level is primarily done via the GlobalTimeDomain instance.

[TPS_SYST_02103] Semantics of GlobalTimeDomain ⌈GlobalTimeDomain represents a specific time source, e.g. GPS time.⌋

[1]For the intents and purposes of this chapter, always make sure to read **global-time domain** rather than **global time-domain**.

In AUTOSAR Releases prior to R23-11 there was also the restriction that all network representations of the same global time domain had to have the identical GlobalTimeDomain.domainId:

In a chain of GlobalTimeDomain.globalTimeSubDomain the value of the attribute GlobalTimeDomain.domainId had to be identical.

This restriction is no longer applied. If however a network compatibility between pre AUTOSAR R23-11 ECUs and current ECUs has to be achieved, then this restriction still needs to be respected (refer to previous versions of this document for details how to configure GlobalTimeDomain.domainId for compatibility).

The modeling of GlobalTimeDomains and SubDomains describes the propagation of time values of a time source through the networks. Note that these SubDomains might use different GlobalTimeDomain.domainId values on different networks.

[constr_9302] Existence of GlobalTimeDomain.domainId

Imposition time: IT_SysDesc

⌈If a GlobalTimeDomain defines a GlobalTimeDomain.globalTimeMaster or GlobalTimeDomain.slave, then the attribute GlobalTimeDomain.domainId shall exist.⌋

[TPS_SYST_05007] separation of roles within a GlobalTimeDomain ⌈Within a single *global time domain*, There is a strict separation of roles into a single *global time master* (formalized by the meta-class GlobalTimeMaster) and a collection of so-called *global time slaves* (formalized by means of the meta-class GlobalTimeSlave).

The role of the GlobalTimeMaster is to provide the global time information and the role of the collection of GlobalTimeSlaves is to consume the information. The chaining of GlobalTimeDomains needs to be understood as the intention to implement the following information flow:

1. from the GlobalTimeMaster of one GlobalTimeDomain to the GlobalTimeSlaves of the same GlobalTimeDomain
2. via the GlobalTimeMaster of the GlobalTimeDomain referenced in the role globalTimeSubDomain to the GlobalTimeSlaves of the globalTimeSubDomain

⌋

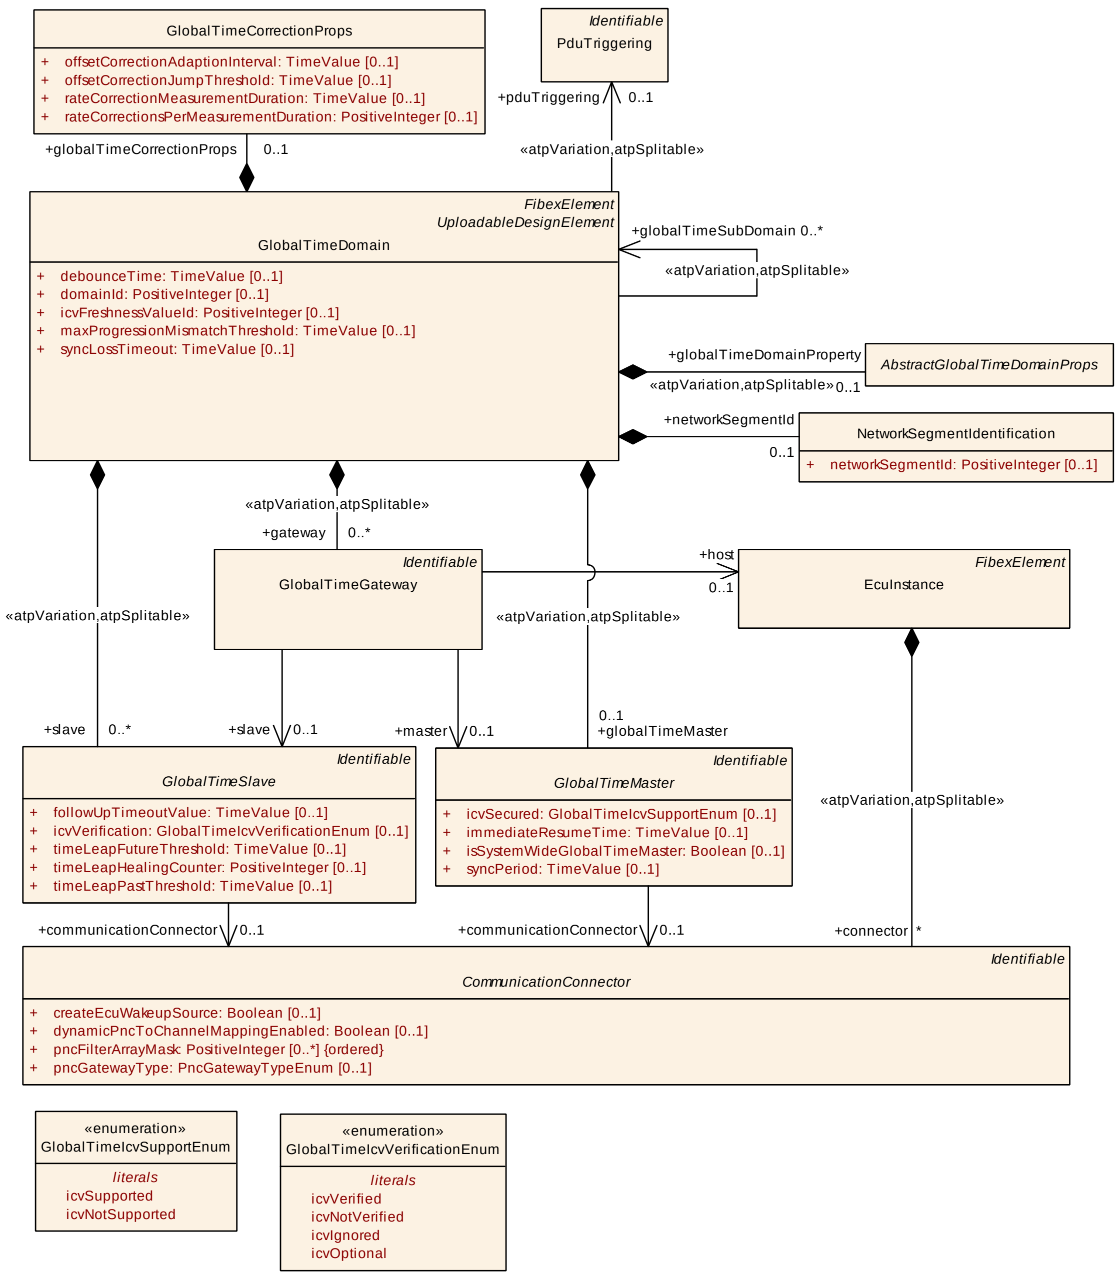

Figure 9.1: Big Picture of AUTOSAR global time synchronization

[TPS_SYST_05008] Semantics of a `GlobalTimeGateway` ⌈In order to achieve the flow of information between a `GlobalTimeSlave` of a given `GlobalTimeDomain` to the `GlobalTimeMaster` of another `GlobalTimeDomain`, it is necessary to establish the existence of a so-called `GlobalTimeGateway`.

In terms of functionality, a `GlobalTimeGateway` complements the functionality of the underlying `Gateway` such that, on top of the mere routing from one `CommunicationCluster` to another, the time information is actively updated in the process of passing it from one `GlobalTimeDomain` to the other.⌋

[TPS_SYST_05009] GlobalTimeDomain.pduTriggering for transmitting global time information ⌈The flow of global time information is unidirectional, i.e. the GlobalTimeSlaves consume the information without providing any form of feedback to the corresponding GlobalTimeMaster.

Thanks to this conceptual detail, there is only the need for **one** dedicated Pdu for the transmission of the actual global time information in the context of one GlobalTimeDomain.

The characteristics of accessing the information contained in this Pdu do make any requirements on the nature of the Pdu. Therefore, it is sufficient and applicable to use the GeneralPurposePdu for this use case.

To make this possible, it is necessary to include the global time use case in the set of standardized values of the attribute GeneralPurposePdu.category. In other words, [constr_3081] applies.⌋

[constr_3261] GlobalTimeDomain.pduTriggering category

Imposition time: IT_SysDesc

⌈The Pdu that is referenced by the PduTriggering that in turn is referenced by GlobalTimeDomain in the role pduTriggering shall be a GeneralPurposePdu of category GLOBAL_TIME.⌋

[TPS_SYST_05010] GlobalTimeDomain.pduTriggering is not required on Ethernet ⌈The Pdu for transmitting global time information is not required on the Ethernet bus. Here, the information is accessed directly from the Ethernet Interfaces, i.e. the hardware already keeps track of the global time.⌋

[constr_1369] CommunicationConnectors shall be attached to the same CommunicationCluster

Imposition time: IT_SysDesc

⌈All CommunicationConnectors referenced from GlobalTimeMaster and GlobalTimeSlaves aggregated in one GlobalTimeDomain shall be referenced in the role commConnector by the same PhysicalChannel aggregated by the same CommunicationCluster.⌋

[constr_1370] Consistency of GlobalTimeDomain

Imposition time: IT_SysDesc

⌈The GlobalTimeSlave referenced in the role GlobalTimeGateway.slave and the GlobalTimeMaster referenced in the role GlobalTimeGateway.master shall **not** be aggregated by the same GlobalTimeDomain.⌋

The background of [constr_1370] is that the GlobalTimeGateway is supposed to connect two GlobalTimeDomains it is hardly possible that the GlobalTimeGateway.slave and the GlobalTimeMaster can be aggregated by the same GlobalTimeDomain.

[TPS_SYST_05011] Ownership of GlobalTimeGateway ⌈Since the existence of a GlobalTimeGateway is only justified if a GlobalTimeDomain exists that is referenced by a GlobalTimeDomain in the role globalTimeSubDomain it seems appropriate to aggregate the GlobalTimeGateway at the GlobalTimeDomain referenced in the role globalTimeSubDomain.⌋

In other words, the GlobalTimeGateway shall be aggregated at the GlobalTimeDomain that also aggregates the master.

Please note that GlobalTimeDomain.gateway effectively has a 0..1 multiplicity since no more than one globalTimeMaster is allowed per GlobalTimeDomain.

[constr_1371] Consistency of attribute host

Imposition time: IT_SysDesc

⌈Within the context of an aggregating GlobalTimeDomain, the CommunicationConnectors referenced in the role GlobalTimeGateway.master.communicationConnector and GlobalTimeGateway.slave.communicationConnector shall be aggregated by the same EcuInstance that is referenced in the role GlobalTimeGateway.host.⌋

[constr_1372] Consistency of attribute pduTriggering

Imposition time: IT_SysDesc

⌈Within the context of an aggregating GlobalTimeDomain, the pduTriggering shall be owned by PhysicalChannel that is also referencing the CommunicationConnectors referenced in the roles GlobalTimeSlave.communicationConnector and GlobalTimeMaster.communicationConnector.⌋

[TPS_SYST_05013] Semantics of GlobalTimeMaster.isSystemWideGlobalTimeMaster ⌈The attribute GlobalTimeMaster.isSystemWideGlobalTimeMaster indicates whether a given GlobalTimeMaster is considered an independent (i.e. [constr_1373] applies) source of global time information.⌋

[constr_1373] GlobalTimeMaster with attribute isSystemWideGlobalTimeMaster set to TRUE

Imposition time: IT_SysDesc

⌈GlobalTimeMaster with attribute isSystemWideGlobalTimeMaster set to TRUE shall not be referenced in the role GlobalTimeGateway.master.⌋

[TPS_SYST_05014] **GlobalTimeMaster.isSystemWideGlobalTimeMaster**
⌈There is no limitation regarding the number of GlobalTimeMasters that have attribute isSystemWideGlobalTimeMaster set to TRUE. The attribute does not imply that there can only be one GlobalTimeMaster within the context of a System.⌋

[constr_1374] Only fan-out possible for GlobalTimeGateway

Imposition time: IT_SysDesc

⌈For all GlobalTimeGateways that refer to the same EcuInstance the condition applies that no two GlobalTimeGateways shall refer to the same GlobalTimeMaster.⌋

In other words, a fan-in of time information such that time information is received from several sources is not supported.

GlobalTime sub domains are associated with specific PhysicalChannels (via the PduTriggerings of GeneralPurposePdus with category GLOBAL_TIME, see [constr_3081]).

In order to identify the PhysicalChannel on a system scope, the NetworkSegmentIdentification.networkSegmentId is used.

The networkSegmentId is derived into the ECU Configuration of every GlobalTime sub domain participant and is available to the TimeSync modules.

One specific use-case is the identification of dedicated PhysicalChannels for the Time Validation (see [44]), where a central entity receives time validation notifications from network nodes of several GlobalTime subdomains and needs to match the respective notifications according to the networkSegmentId.

[constr_3620] GlobalTimeDomain.networkSegmentId only applicable to GlobalTime sub domains

Imposition time: IT_SysDesc

⌈The aggregation GlobalTimeDomain.networkSegmentId shall only be defined if the GlobalTimeDomain is itself referenced in the role GlobalTimeDomain.globalTimeSubDomain.⌋

Rational: There is a GlobalTime sub domain defined for each network the GlobalTime is distributed to, thus only for GlobalTime sub domains a definition of a networkSegmentId makes sense.

Note that the GlobalTimeDomain.networkSegmentId is currently not taken to the ECU Configuration of the EthTSyn module, as there are other means used for the identification of EthTSyn network segments (see [45]).

[constr_3621] Value range of GlobalTimeDomain.networkSegmentId

Imposition time: IT_SysDesc

⌈If defined, the value of GlobalTimeDomain.networkSegmentId shall be in the range 0..255.⌋

It is possible to define that a GlobalTimeDomain is secured for the transport using the Integrity Check Value (ICV). This requires a configuration of the properties used for the calculation and verification of the ICV.

The authentication algorithm and its configuration are defined at the GlobalTimeDomain using the reference GlobalTimeDomain.icvSecureComProps. Additionally the attribute GlobalTimeDomain.icvFreshnessValueId is provided to configure the freshness value calculation and verification.

Class	**SecOcSecureComProps**

Attribute	***Type***	***Mult.***	***Kind***	***Note***
authentication	CryptoServicePrimitive	0..1	ref	This reference defines the authentication algorithm used for MAC generation and verification.
authenticationBuildAttempts	PositiveInteger	0..1	attr	This attribute defines the additional number of authentication build attempts that are to be carried out when the generation of the authentication information failed for a given message. If zero is set then only one authentication attempt is done.
authenticationVerifyAttempts	PositiveInteger	0..1	attr	This attribute defines the additional number of authentication attempts that are to be carried out when the generation of the authentication information failed for a given message. If zero is set than only one authentication attempt is done.
authInfoTxLength	PositiveInteger	0..1	attr	This attribute defines the length in bits of the authentication code to be included in the payload of the authenticated Message.
freshnessValueLength	PositiveInteger	0..1	attr	This attribute defines the complete length in bits of the Freshness Value.
freshnessValueTxLength	PositiveInteger	0..1	attr	This attribute defines the length in bits of the Freshness Value to be included in the payload of the secured message.
jobRequirement	SecOcJobRequirement	*	aggr	Collection of cryptographic job requirements.

Table 9.1: SecOcSecureComProps

Each GlobalTimeMaster of the GlobalTimeDomain can individually define whether the Integrity Check Value (ICV) shall be calculated and transported for that GlobalTimeMaster's network.

[TPS_SYST_03125] Enabling sending of GlobalTimeDomain Integrity Check Value (ICV) ⌈The attribute GlobalTimeMaster.icvSecured setting to GlobalTimeIcvSupportEnum.icvSupported enables the calculation and sending of the ICV on the network that GlobalTimeMaster is responsible for.⌋

Each GlobalTimeSlave of the GlobalTimeDomain can individually define whether the Integrity Check Value (ICV) shall be verified (if received).

[TPS_SYST_03126] Enabling verification of GlobalTimeDomain Integrity Check Value (ICV) ⌈The attribute GlobalTimeSlave.icvVerification defines the reception behavior of the ICV on the network that GlobalTimeSlave is responsible for.⌋

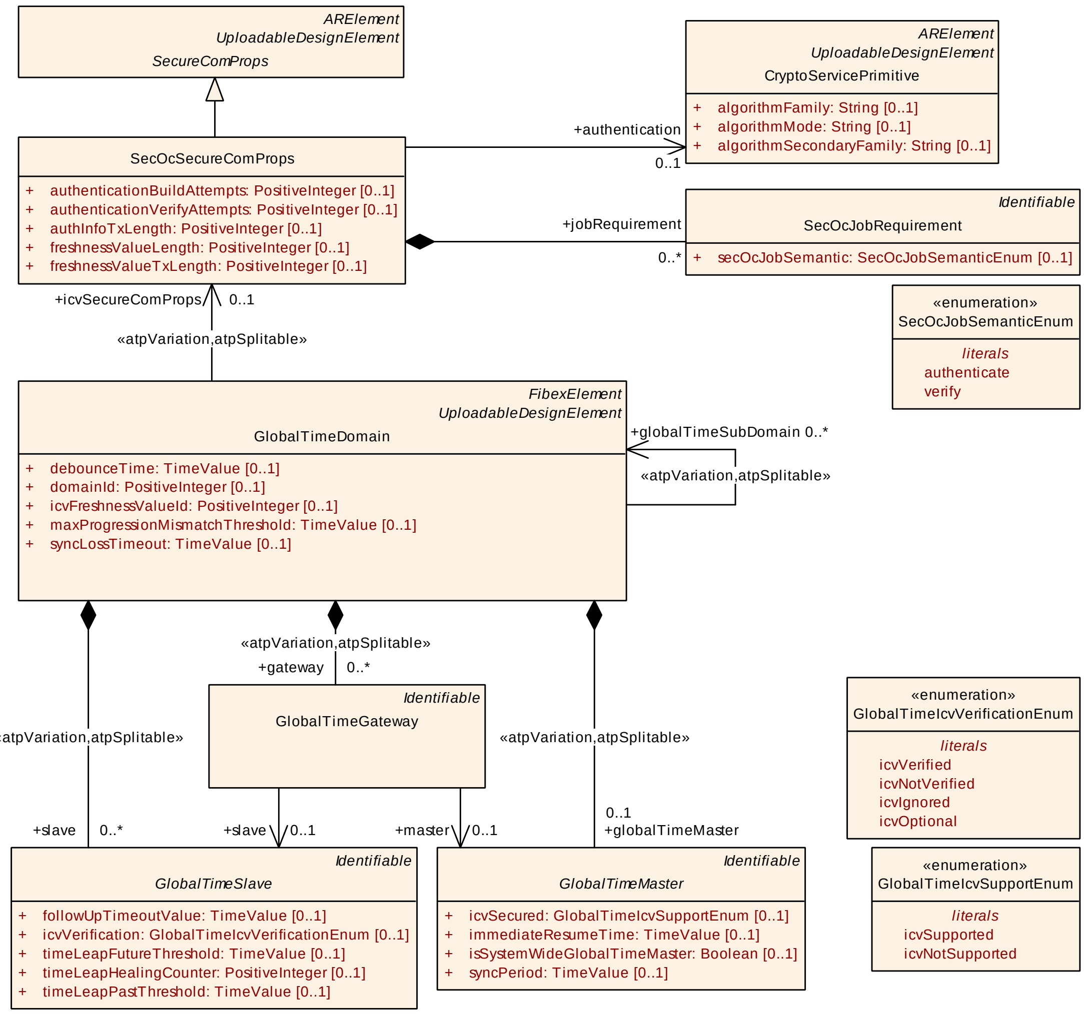

Figure 9.2: Global Time Sync with Integrity Check Value (ICV)

In figure 9.3 an example of a Global Time Sync setup is shown. The *Global time master* ECU creates the *TimeDomain* and provides it to several globalTimeSubDomains.

The GlobalTimeMasters for the globalTimeSubDomains take the *TimeDomain* and distribute it to their networks.

The time for the GlobalTimeMasters *TM11* and *TM21* is based on the *TimeDomain* and therefore they have the attribute isSystemWideGlobalTimeMaster set to *true*.

The time for the GlobalTimeMasters *TM12* and *TM22* are based on a GlobalTimeGateway and therefore they have the attribute isSystemWideGlobalTimeMaster set to *false*.

Attribute	***Type***	***Mult.***	***Kind***	***Note***
offsetCorrectionAdaptionInterval	TimeValue	0..1	attr	Defines the interval during which the adaptive rate correction cancels out the rate- and time deviation.
offsetCorrectionJumpThreshold	TimeValue	0..1	attr	Threshold for the correction method. Deviations below this value will be corrected by a linear reduction over a defined timespan. Values equal- and greater than this value will be corrected by immediately setting the correct time- and rate in form of a jump.
rateCorrectionMeasurementDuration	TimeValue	0..1	attr	Definition of the time span which is used to calculate the rate deviation.
rateCorrectionsPerMeasurementDuration	PositiveInteger	0..1	attr	Defines the number of simultaneous rate measurements to determine the current rate deviation.

Table 9.8: GlobalTimeCorrectionProps

9.2.1 Reverse Sync Method

The AUTOSAR_FO_EXP_TimeSensitiveNetworkFeatures [46] mentions several methods how the quality (accuracy) of the global time at a GlobalTimeSlave can be measured. These are development features which can be enabled to perform measurements for a specific EcuInstance.

The Reverse Sync Method has the special approach that a GlobalTimeSlave takes the synchronized global time he synchronizes to and clones this time back to the network using a different GlobalTimeDomain, i.e. a different GlobalTimeDomain.domainId.

This Reverse Sync may be activated for the sole purpose of measurement and debugging. In a production ECU this Reverse Sync will typically be turned off.

The Reverse Sync might use a PhysicalChannel where already one or more GlobalTimeDomains are communicated on and thus, the number of GlobalTimeDomain.domainId may run short. So typically there is one domainId used to handle the Reverse Sync of all connected EcuInstances. The assumption is, that only up to one of the connected EcuInstances will actually turn on the Reverse Sync and thus use the respective domainId.

From the PhysicalChannel there are several GlobalTimeMasters defined which all use the same GlobalTimeDomain.domainId value. As long as only one of these GlobalTimeMasters becomes active at the same time this setup operates properly.

[TPS_SYST_02403] Usage of an identical GlobalTimeDomain.domainId in the GlobalTimeMaster role on one PhysicalChannel ⌈It is a valid configuration to define several GlobalTimeMasters with an identical GlobalTimeDomain.domainId on the same PhysicalChannel. During runtime it shall be guaranteed that only up to one of the GlobalTimeMasters is active at any point in time.⌋

9.3 Detailed Description of Global Time Synchronization

This chapter describes how the concept of *global time synchronization* is applied to various communication bus systems.

Although the characteristics of the supported bus systems differ widely in terms of their communication behavior, the modeling is actually quite similar for all of the supported bus systems.

9.3.1 Time Synchronization over CAN

This chapter described the detailing of how the concept of *global time synchronization* is applied to the CAN bus in particular.

The implementation of *global time synchronization* on the CAN bus is modeled by means of GlobalTimeCanMaster, a concrete subclass of GlobalTimeMaster. A similar approach applies for the GlobalTimeCanSlave, which is derived from GlobalTimeSlave.

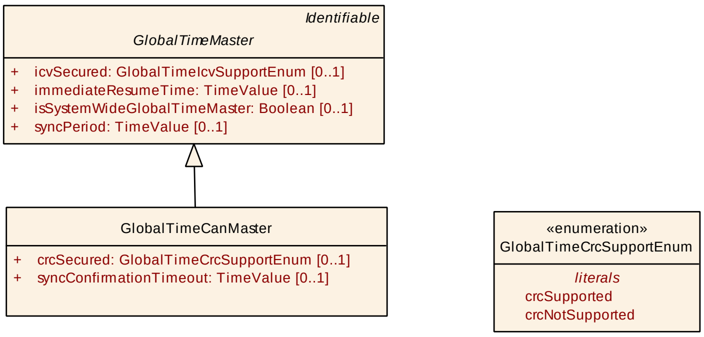

Figure 9.7: Modeling of the `GlobalTimeCanMaster`

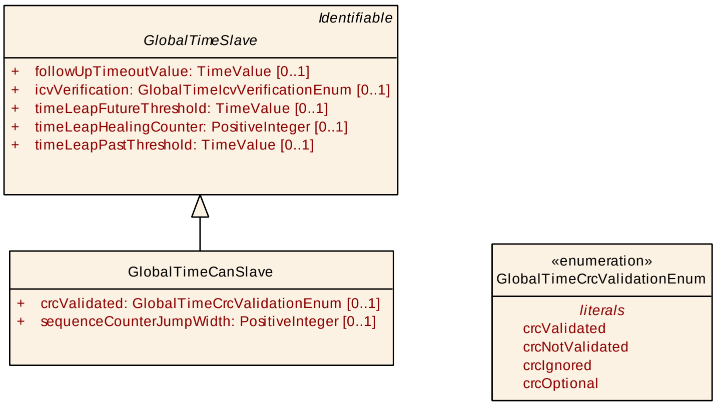

Figure 9.8: Modeling of the `GlobalTimeCanSlave`

In addition to the CAN specific Master and Slave properties CAN specific `CanGlobalTimeDomainProps` can be described.

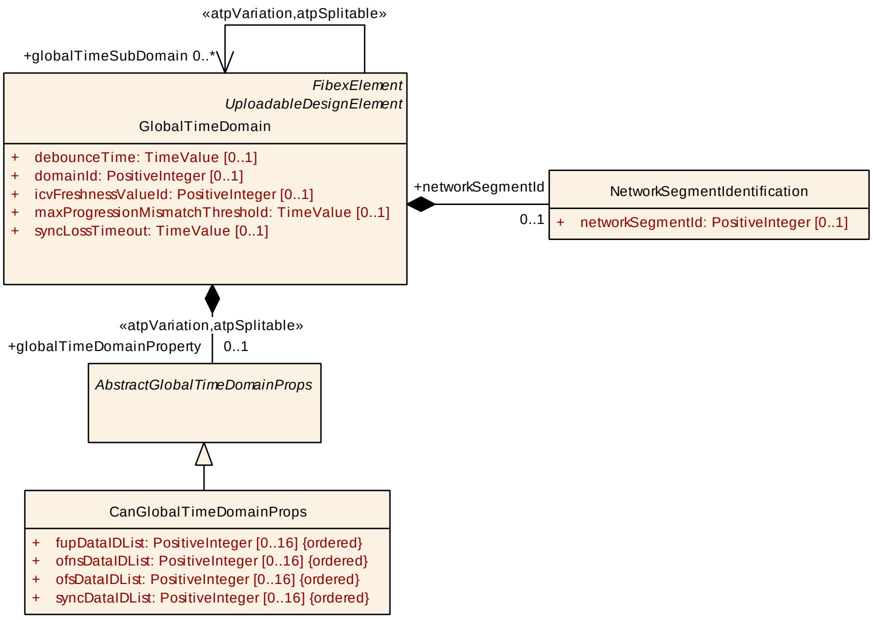

Figure 9.9: Modeling of the CAN specific `CanGlobalTimeDomainProps`

9.3.2 Time Synchronization over Ethernet

This chapter described the detailing of how the concept of *global time synchronization* is applied to the Ethernet bus in particular. For details concerning the functional behavior please refer to [45].

The implementation of *global time synchronization* on the Ethernet bus is modeled by means of `GlobalTimeEthMaster`, a concrete subclass of `GlobalTimeMaster`. A similar approach applies for the `GlobalTimeEthSlave`, which is derived from `GlobalTimeSlave`.

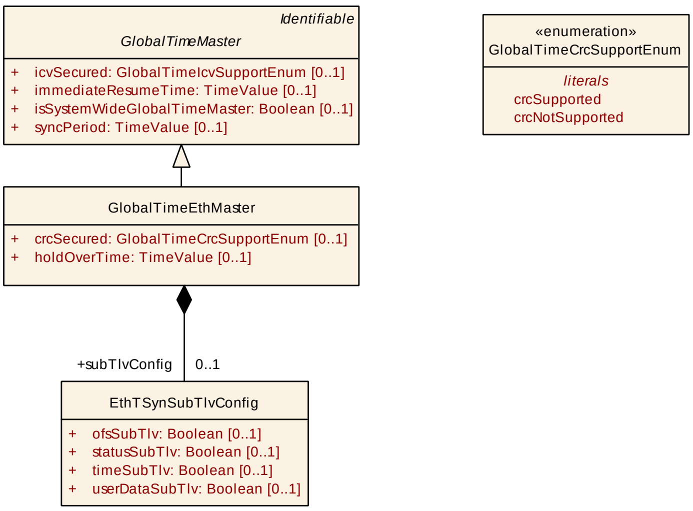

Figure 9.10: Modeling of the `GlobalTimeEthMaster`

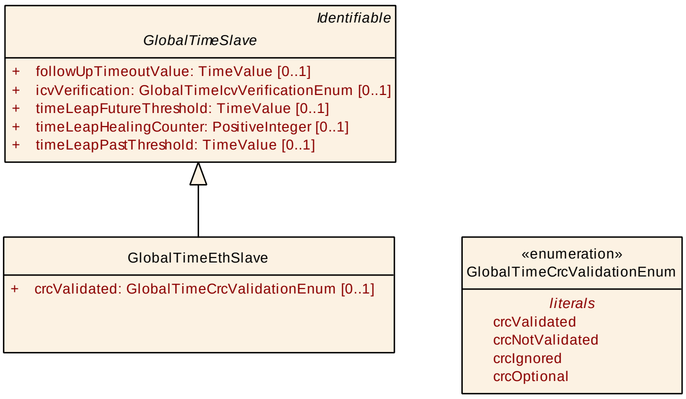

Figure 9.11: Modeling of the GlobalTimeEthSlave

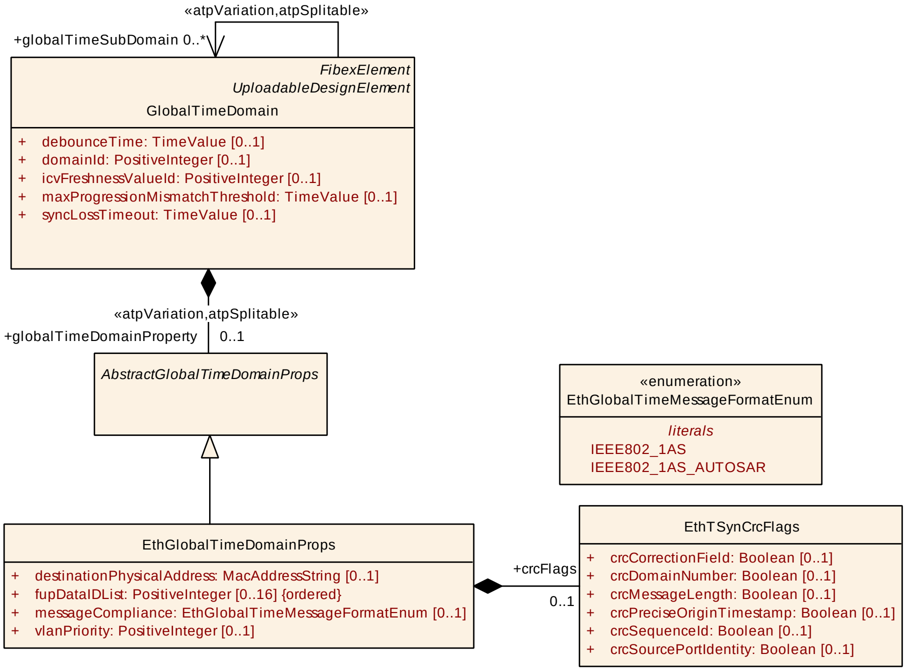

Figure 9.12: Modeling of the EthGlobalTimeDomainProps

Class	**GlobalTimeEthMaster**			
Package	M2::AUTOSARTemplates::SystemTemplate::GlobalTime::ETH

IEEE802_1AS_ AUTOSAR	Message format according to IEEE 802.1AS standard with AUTOSAR extensions. **Tags:** atp.EnumerationLiteralIndex=1 xml.name=IEEE802-1AS-AUTOSAR

Table 9.17: EthGlobalTimeMessageFormatEnum

[constr_3312] Consistency of vlanPriority and EthernetCommunicationConnector

Imposition time: IT_SysDesc

⌈A GlobalTimeEthMaster refers to an EthernetCommunicationConnector in the role communicationConnector. If that EthernetCommunicationConnector is referenced by an EthernetPhysicalChannel in the role commConnector and the EthernetPhysicalChannel has a vLan tag defined via the VlanConfig then the GlobalTimeDomain of the GlobalTimeEthMaster shall aggregate EthGlobalTimeDomainProps in the role globalTimeDomainProperty and the attribute EthGlobalTimeDomainProps.vlanPriority shall exist.⌋

In Ethernet networks the usage of Ethernet switches introduces another layer of delay in the transportation of data. This of course also applies to the global time synchronization messages and there are means to compensate these delays available in AUTOSAR.

In order to cope with delays on global time sync of Ethernet transport technology two use-cases are supported:

- an ECU is connected to an Ethernet switch but does not manage the switch (see section 9.3.2.2)
- an ECU is connected to an Ethernet switch and also manages this switch (see section 9.3.2.3)

The CouplingPort is used in either use-case to describe the connection of the ECU to the Ethernet network / switch. Thus there are some attributes related to the CouplingPort which apply to both use-cases.

9.3.2.1 Time Synchronization and Ethernet propagation delay

The propagation delay measurement is applicable to the CouplingPort in scope of the global time synchronization.

The default propagation delay time (which is used if propagation delay measurement is disabled or is not yet measured) is defined at the GlobalTimeCouplingPortProps with the attribute propagationDelay. The GlobalTimeCouplingPortProps are aggregated at the CouplingPortDetails in the role globalTimeProps.

Whether an ECU shall initiate a propagation delay measurement at a certain CouplingPort and on a specific GlobalTimeDomain is defined by the attribute pdelayRequestPeriod at the EthGlobalTimeManagedCouplingPort.

[TPS_SYST_03016] Applicability of EthGlobalTimeManagedCouplingPort.pdelayRequestPeriod ⌈When EthGlobalTimeManagedCouplingPort.pdelayRequestPeriod is not defined or has the value 0 then initiation of propagation delay measurement is disabled for the CouplingPort referenced by couplingPort and the GlobalTimeDomain the EthGlobalTimeManagedCouplingPort belongs to.⌋

Whether an ECU shall respond to propagation delay measurement at a certain CouplingPort and on a specific GlobalTimeDomain is defined by the attribute pdelayResponseEnabled at the EthGlobalTimeManagedCouplingPort.

9.3.2.2 Time Synchronization and Ethernet connection

In case the ECU is directly connected to the Ethernet network and does not manage an Ethernet switch (of course there may be Ethernet switches used in the topology, but for this use-case these switches are not visible to the description of this ECU) the Ethernet time synchronization only needs to cope with the connection of this ECU to the Ethernet network. Considering the example in figure 9.14 this applies to the ECUs TS1, TS2, TS3, and TM which are just connected to the Ethernet switches but do not manage any Ethernet switch.

[TPS_SYST_03017] Reference to CouplingPort in the context of a GlobalTimeDomain ⌈In case a GlobalTimeDomain is communicated via a CouplingPort and the respective ECU does not manage an Ethernet switch then the reference EthGlobalTimeManagedCouplingPort.couplingPort shall reference a CouplingPort which is aggregated by the EthernetCommunicationController in the role couplingPort. The EthernetCommunicationController itself shall be referenced by a GlobalTimeMaster or GlobalTimeEthSlave (via the CommunicationConnector) and that GlobalTimeMaster or GlobalTimeEthSlave shall be aggregated by the GlobalTimeDomain initially mentioned.⌋

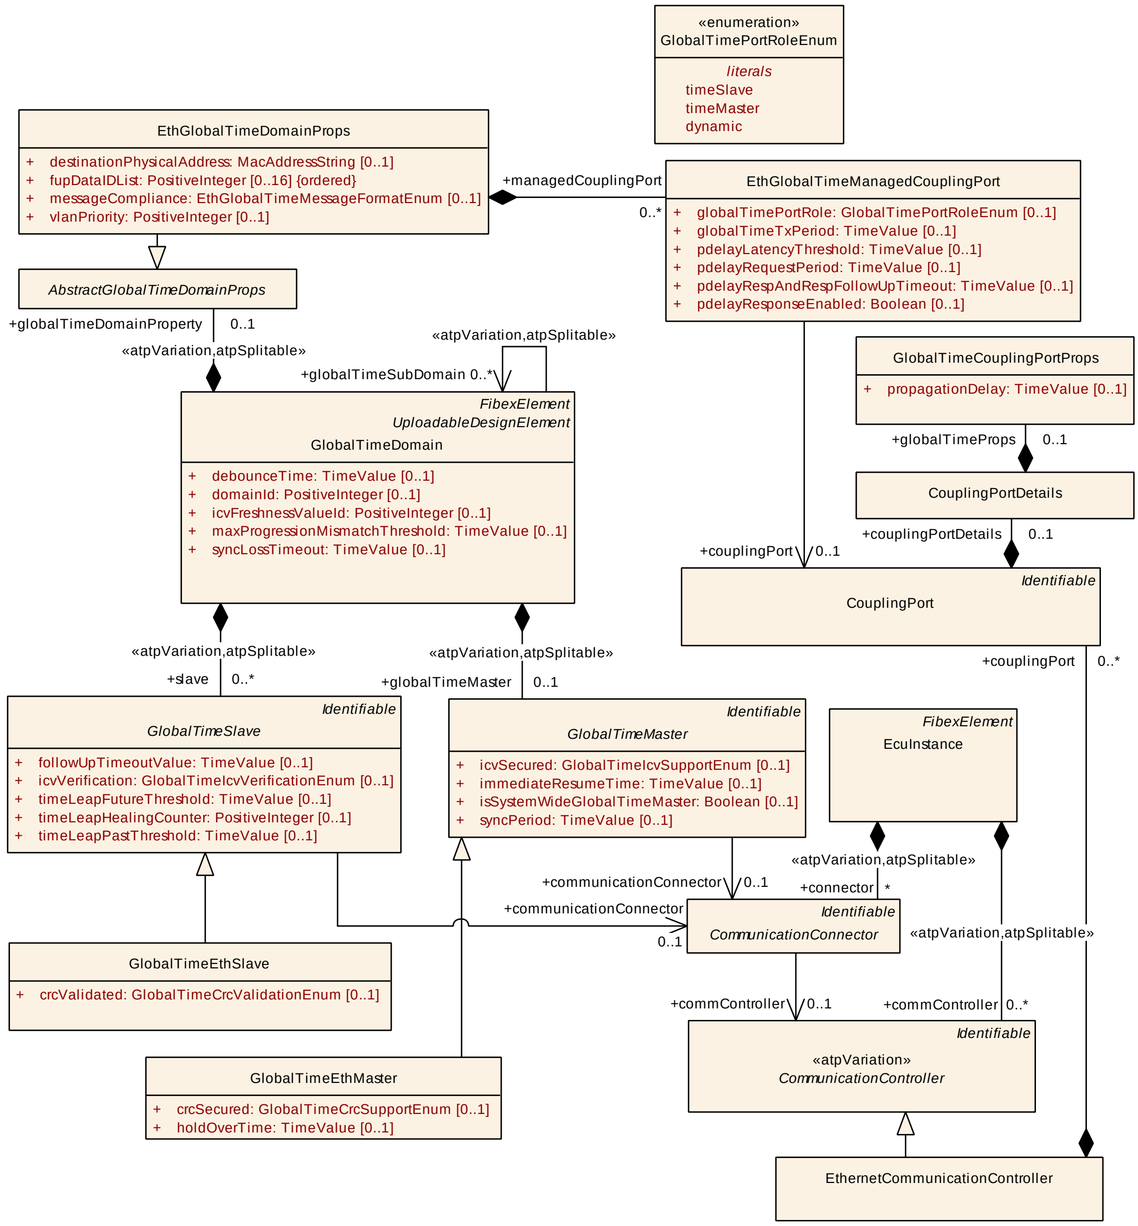

Figure 9.13: Overview of the Ethernet time sync in relation with a `CouplingPort` of an ECU

9.3.2.3 Time Synchronization and managed Ethernet switch

In case an ECU manages an Ethernet switch then that management ECU can basically be the `GlobalTimeEthMaster` or the `GlobalTimeEthSlave` located (see also figure 9.14). For the description of the time delay compensation on System Template level this does not matter.

It is essential to configure all possible time synchronization communication paths between the involved entities.

In case of ECU A in figure 9.14 the GlobalTimeEthMaster shall

- refer to the CouplingPort 0 since this is where
  - all time sync messages will be sent out by the GlobalTimeEthMaster
  - all adjusted follow up messages will be sent out by the GlobalTimeEthMaster
- refer to the CouplingPort 1 because this is where the Ethernet switch is connected to the management ECU A
- refer to the CouplingPorts 2, 3, and 4 since this is where the time sync messages will be forwarded by the switch
- not refer to the CouplingPort 5 because this one is not involved in that GlobalTimeDomains communication

In case of ECU B in figure 9.14 the GlobalTimeEthSlave shall

- refer to the CouplingPort 0 since this is where
  - the time sync messages will be received by the GlobalTimeEthSlave
  - all adjusted follow up messages will be sent out by the GlobalTimeEthSlave
- refer to the CouplingPort 1 because this is where the Ethernet switch is connected to the management ECU B
- refer to the CouplingPort 3 because this is where the time sync messages will be received from the GlobalTimeEthMaster on ECU TM
- refer to the CouplingPorts 2 and 4 since this is where the time sync messages will be forwarded by the switch
- not refer to the CouplingPort 5 because this one is not involved in that GlobalTimeDomains communication

Please note that the non-involvement of the CouplingPort 5 is used for illustration purposes. It would also be possible to involve CouplingPort 5 in that GlobalTimeDomain definition although currently there is no ECU as an GlobalTimeEthSlave defined. In that case the CouplingPort 5 is prepared to be connected to an ECU with an GlobalTimeEthSlave later.

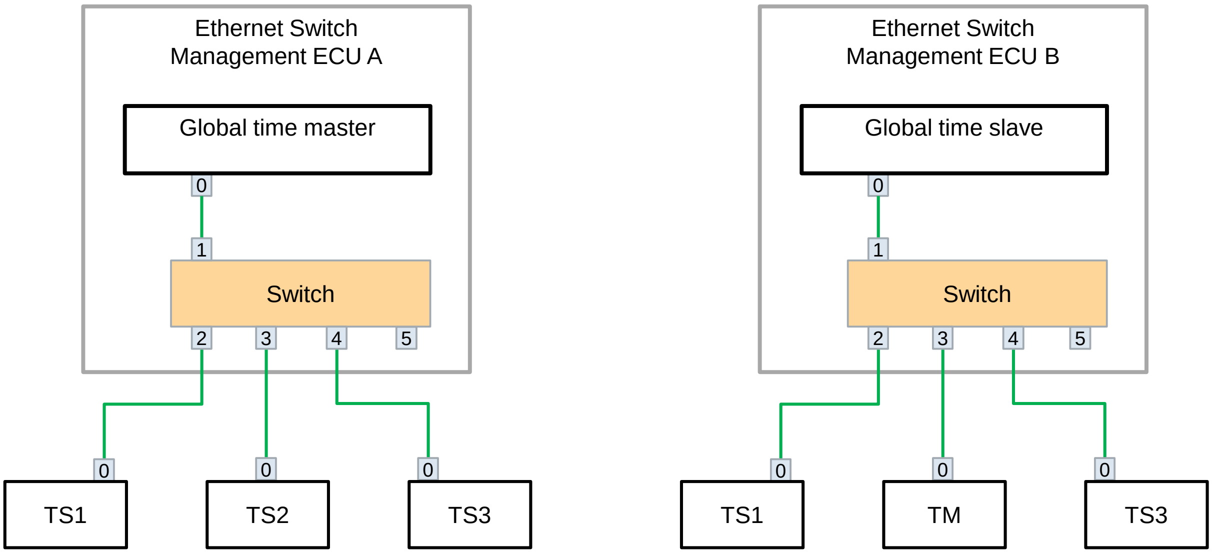

Figure 9.14: Example of a managed Ethernet Switch

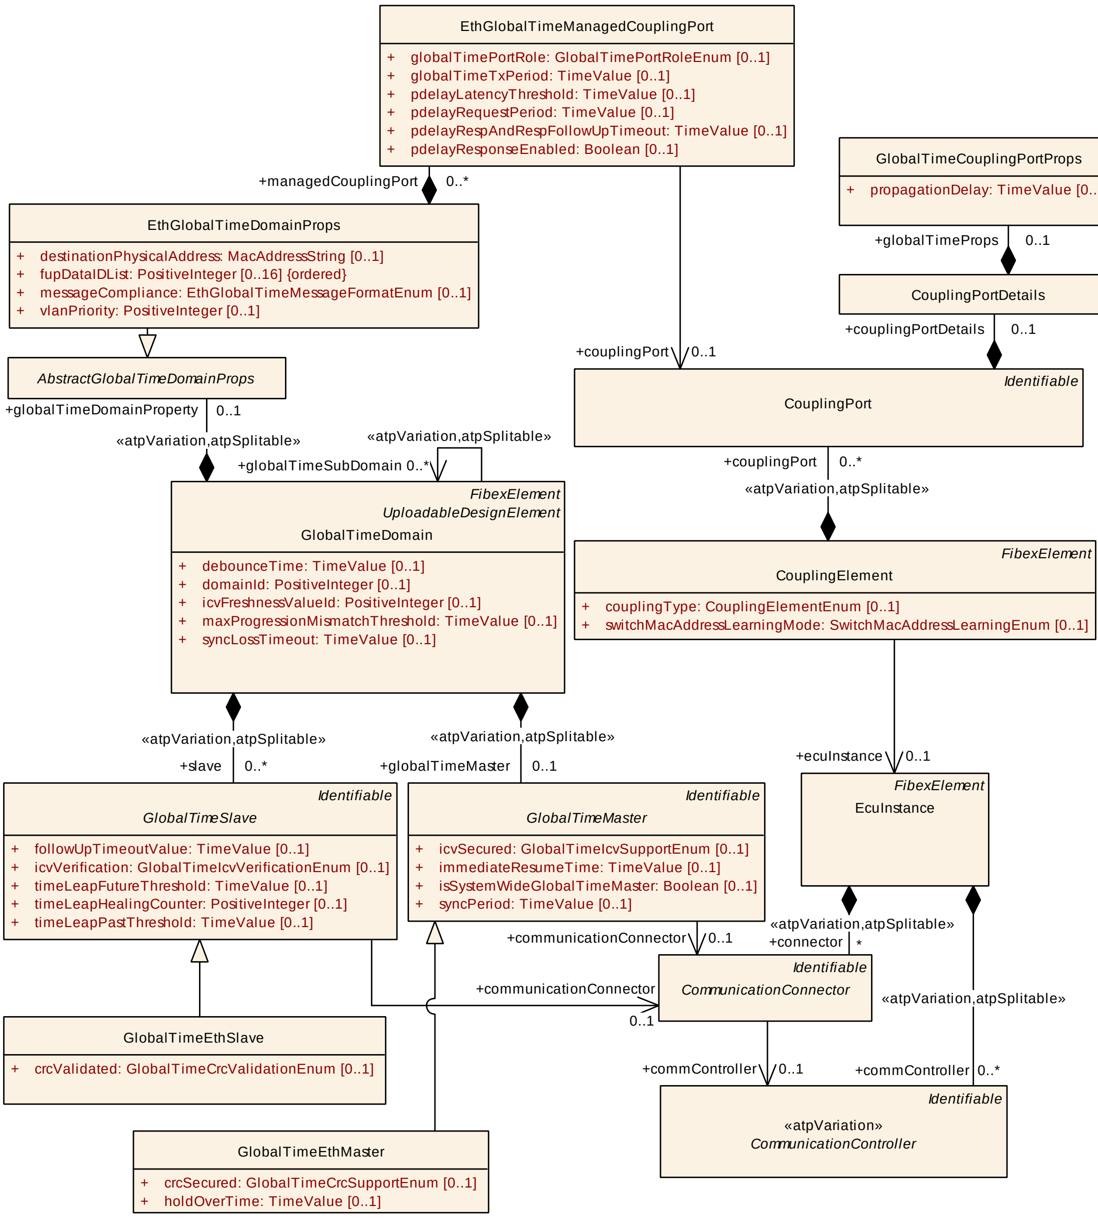

Figure 9.15: Overview of the Ethernet time sync in relation with a `CouplingPort` of an Ethernet switch

Class	**EthGlobalTimeManagedCouplingPort**

Note	Defines properties for the usage of the CouplingPort in the scope of Global Time Sync.			
Base	*ARObject*			
Aggregated by	CouplingPortDetails.globalTimeProps			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
propagation Delay	TimeValue	0..1	attr	If cyclic propagation delay measurement is enabled, this parameter represents the default value of the propagation delay until the first actually measured propagation delay is available. If cyclic propagation delay measurement is disabled, this parameter defines a fixed value for the propagation delay.

Table 9.19: GlobalTimeCouplingPortProps

[constr_9312] Existence of EthGlobalTimeManagedCouplingPort.pdelayResponseEnabled

Imposition time: IT_SysDesc

⌈For each EthGlobalTimeManagedCouplingPort, the attribute pdelayResponseEnabled shall exist.⌋

[constr_9313] Existence of GlobalTimeCouplingPortProps.propagationDelay

Imposition time: IT_SysDesc

⌈For each GlobalTimeCouplingPortProps, the attribute propagationDelay shall exist.⌋

Enumeration	GlobalTimePortRoleEnum
Package	M2::AUTOSARTemplates::SystemTemplate::GlobalTime::ETH
Note	Selection of port behavior to Time Slave, Time Master or Dynamic (Time Slave or Time Master at runtime).
Aggregated by	EthGlobalTimeManagedCouplingPort.globalTimePortRole
Literal	***Description***
dynamic	Time Slave or Time Master port behavior at runtime. **Tags:** atp.EnumerationLiteralIndex=2
timeMaster	timeMaster port behavior **Tags:** atp.EnumerationLiteralIndex=1
timeSlave	TimeSlave port behavior **Tags:** atp.EnumerationLiteralIndex=0

Table 9.20: GlobalTimePortRoleEnum

[constr_5389] Dependency between globalTimeTxPeriod and globalTimePortRole

Imposition time: IT_SysDesc

⌈The attribute EthGlobalTimeManagedCouplingPort.globalTimeTxPeriod shall only be set to a value if the attribute EthGlobalTimeManagedCouplingPort.globalTimePortRole is set to timeMaster or dynamic.⌋

The reason for [constr_5389] is that EthGlobalTimeManagedCouplingPort.globalTimeTxPeriod determines the transmission interval of Sync messages.

[constr_5390] The globalTimePortRole shall not be configured to timeSlave several times in the same GlobalTimeDomain

Imposition time: IT_SysDesc

⌈The attribute globalTimePortRole shall not be set to timeSlave for two or more EthGlobalTimeManagedCouplingPorts that are aggregated by the same GlobalTimeDomain (via globalTimeDomainProperty).⌋

9.3.3 Time Synchronization over FlexRay

This chapter described the detailing of how the concept of *global time synchronization* is applied to the Flexray bus in particular.

The implementation of *global time synchronization* on the Flexray bus is modeled by means of GlobalTimeFrMaster, a concrete subclass of GlobalTimeMaster. A similar approach applies for the GlobalTimeFrSlave, which is derived from GlobalTimeSlave.

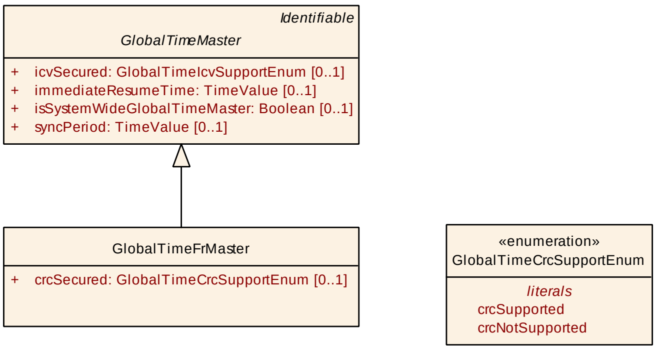

Figure 9.16: Modeling of the `GlobalTimeFrMaster`

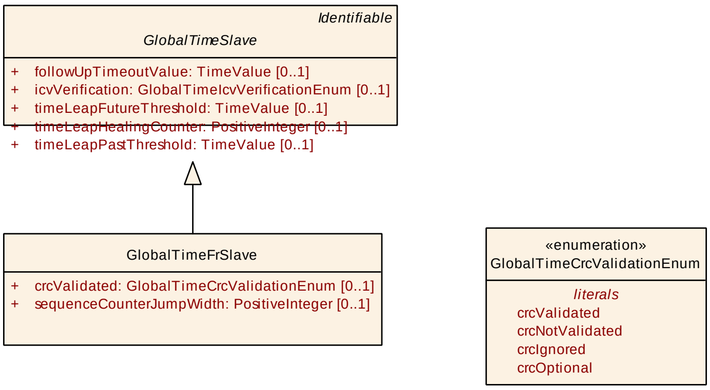

Figure 9.17: Modeling of the `GlobalTimeFrSlave`

In addition to the FlexRay specific Master and Slave properties FlexRay specific `FrGlobalTimeDomainProps` can be described.

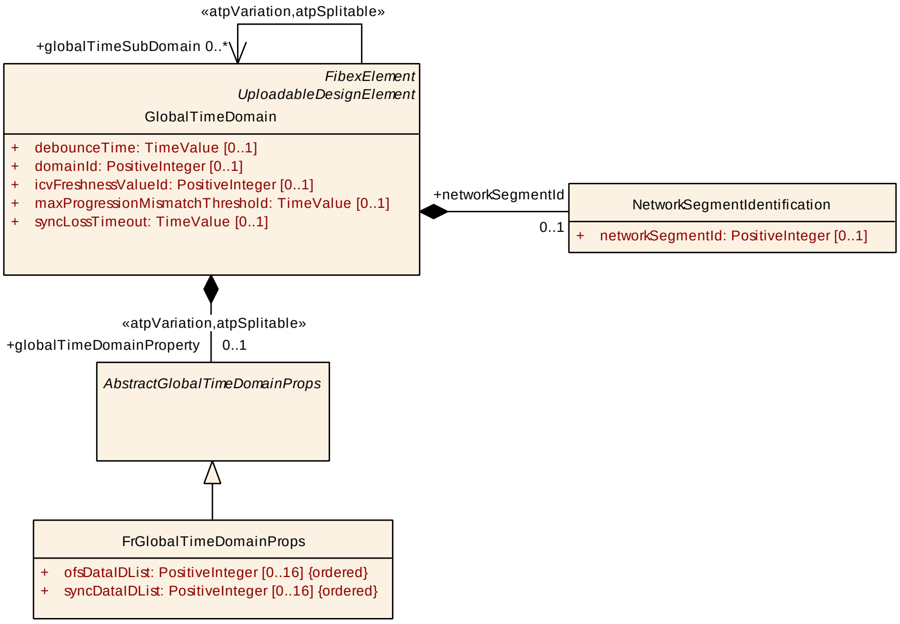

Figure 9.18: Modeling of the FlexRay specific `FrGlobalTimeDomainProps`

10 Description of Service Discovery Services in Classic Platform

10.1 Representation of Service Interfaces on VFB level

ServiceInterfaces in the Adaptive Platform and in SOME/IP consist of Events, Fields and Methods. AUTOSAR classic platform does not support ServiceInterfaces but provides the possibility to communicate in a service oriented way over SOME/IP.

To mimic a ServiceInterface in the Classic Platform any combination of ClientServerInterfaces, SenderReceiverInterfaces or TriggerInterfaces may be used.

[TPS_SYST_02283] Collection of ServiceInterface elements ⌈The collection of PortInterfaces that represent one ServiceInterface shall be wrapped by a Collection element with category SET and collectionSemantics SO_SERVICE_INTERFACE.⌋

An example of ServiceInterface named *RadarService* is shown in the following listing.

```
<AR-PACKAGE>
  <SHORT-NAME>ServiceInterfaces</SHORT-NAME>
  <ELEMENTS>
    <!-- /ServiceInterfaces/RadarService -->
    <COLLECTION>
      <SHORT-NAME>RadarService</SHORT-NAME>
      <CATEGORY>SET</CATEGORY>
      <COLLECTION-SEMANTICS>SO_SERVICE_INTERFACE</COLLECTION-SEMANTICS>
      <ELEMENT-REFS>
        <ELEMENT-REF DEST="VARIABLE-DATA-PROTOTYPE">/PortInterfaces/
           RadarService_BrakeEvent/BrakeEvent</ELEMENT-REF>
        <ELEMENT-REF DEST="CLIENT-SERVER-OPERATION">/PortInterfaces/
           RadarService_Methods/Calibrate</ELEMENT-REF>
        <ELEMENT-REF DEST="CLIENT-SERVER-OPERATION">/PortInterfaces/
           RadarService_Methods/Adjust</ELEMENT-REF>
        <ELEMENT-REF DEST="COLLECTION">/Fields/RadarService_UpdateRate</
           ELEMENT-REF>
        <ELEMENT-REF DEST="COLLECTION">/FireAndForgetMethods/
           RadarService_FireAndForgetMethods</ELEMENT-REF>
      </ELEMENT-REFS>
    </COLLECTION>
  </ELEMENTS>
</AR-PACKAGE>
```

Listing 10.1: Example for a ServiceInterface Collection

The *RadarService* in this example consist of:

- an Event named *BrakeEvent*,

- a Method named *Calibrate*,
- a Method named *Adjust*,
- a Field named *RadarService_UpdateRate*,
- a Collection of Fire_And_Forget Methods.

10.1.1 Representation of Events

[TPS_SYST_02284] Event in a ServiceInterface ⌈An event in a ServiceInterface shall be described as a VariableDataPrototype in a SenderReceiverInterface.⌋

Please note that in SOME/IP and other description formats like ASAM FIBEX an Event consist of one or several Parameters. In AUTOSAR an Event with several parameters needs to be described as an VariableDataPrototype that is typed by an AutosarDataType of category STRUCTURE. Each parameter of the Event shall be represented as a member of the STRUCTURE.

10.1.2 Representation of Methods

[TPS_SYST_02285] Method in a ServiceInterface ⌈A method of a ServiceInterface shall be described as a ClientServerOperation in a ClientServerInterface.⌋

Each method parameter shall be described as an argument of the ClientServerOperation. Please note that the order of method parameters is expressed by the order of arguments.

10.1.3 Representation of Fire and Forget Methods

A so-called “fire & forget” method in SOME/IP represents a special form of a method dedicated to the sole purpose of conveying information from the service consumer to the service provider. The semantics of a “fire & forget” method is comparable to the semantics of an event, only reverse. In case that the ServiceInterface contains a “fire & forget” method the service consumer is able to call this method without the expectation of any response from the service provider.

[TPS_SYST_02286] “fire & forget” method with data in a ServiceInterface ⌈A “fire & forget” method of a ServiceInterface that contains data shall be described as a VariableDataPrototype in a SenderReceiverInterface. The service provider will consume the VariableDataPrototype. The service consumer will provide the VariableDataPrototype.⌋

If such a “fire & forget” method contains several parameters the VariableDataPrototype shall be typed by an AutosarDataType of category STRUCTURE. Each parameter of the “fire & forget” method shall be represented as a member of the STRUCTURE.

[TPS_SYST_02287] “Fire & forget” method without data in a ServiceInterface
⌈A “fire & forget” method of a ServiceInterface that does not contain any data shall be described as a Trigger in a TriggerInterface. The service provider will consume the Trigger. The service consumer will provide the Trigger.⌋

To distinguish “fire & forget” methods with parameters from Events a sub-collection is introduced in the ServiceInterface Collection. The sub-collection refers to all “fire & forget” methods represented as VariableDataPrototypes and Triggers that are defined by the ServiceInterface.

[TPS_SYST_02288] “Fire & forget” method in a ServiceInterface
⌈The “fire & forget” methods of ServiceInterface shall be wrapped by a Collection element with category SET and collectionSemantics SO_SERVICE_FIRE_AND_FORGET_METHODS.⌋

```

           RadarService_Reset/Reset</ELEMENT-REF>
        <ELEMENT-REF DEST="TRIGGER">/PortInterfaces/
           RadarService_LogCurrentState/RadarService_LogCurrentState</
           ELEMENT-REF>
      </ELEMENT-REFS>
    </COLLECTION>
  </ELEMENTS>
</AR-PACKAGE>
```

Listing 10.2: Example for a fire & forget Method Collection

10.1.4 Representation of Fields

A Field represents a piece of data hosted by a server that exposes to one or more client(s) a get accessor and/or a set mutator. Clients can optionally receive notifications of changes of the Field's value. In addition a Field has a concrete value at any time. As soon as the ServiceInterface is offered a Field of this ServiceInterface can be accessed by a client.

[TPS_SYST_02289] Field in a ServiceInterface ⌈The elements of a Field shall be wrapped by a Collection element with category SET and collectionSemantics SO_SERVICE_FIELD.⌋

[TPS_SYST_02290] Field elements ⌈A Collection element with category SO_SERVICE_FIELD is allowed to contain one, two or all three of the following items:

- a reference to a VariableDataPrototype representing a Field Notifier,
- a reference to a ClientServerOperation representing a Field Getter,
- a reference to a ClientServerOperation representing a Field Setter.

⌋

[TPS_SYST_02291] Field Notifier ⌈A Field Notifier is represented by a VariableDataPrototype in a SenderReceiverInterface.⌋

[TPS_SYST_02292] Field Getter ⌈A Field Getter is represented by a ClientServerOperation with ArgumentDataPrototypes with direction out.⌋

After the getter call the requester will receive the current value of the Field in the response.

[TPS_SYST_02293] Field Setter ⌈A Field Setter is represented by a ClientServerOperation with ArgumentDataPrototypes with direction out and in.⌋

Please note that it is the decision of the Service Provider to accept the setter request or to deny it. The current value of the Field will always be sent back to the requester as response.

Listing 10.3: Example for a `Field` `Collection`

[constr_5330] `ServiceInterface` elements shall belong to exactly one `ServiceInterface`

Imposition time: IT_SysDesc

⌈If an element like

- a VariableDataPrototype that represents a ServiceInterface event
- a ClientServerOperation that represents a ServiceInterface method
- a Collection with collectionSemantics SO_SERVICE_FIELD that represents a ServiceInterface field
- a Collection with collectionSemantics SO_SERVICE_FIRE_AND_FORGET_METHOD that represents a "fire & forget" method

is referenced in the role element by a Collection that has the collectionSemantics set to SO_SERVICE_INTERFACE then this element shall not be referenced by any other Collection element that has the collectionSemantics SO_SERVICE_INTERFACE in the scope of the System.⌋

[constr_5330] is introduced to mimic the ServiceInterface modeling in the Adaptive Platform where the Event, Method and Field are aggregated by the ServiceInterface.

10.2 Representation of Service Interfaces on network level

Elements of ServiceInterfaces are mapped by the DataMapping to SystemSignals and later to ISignals and ISignalIPdus for transport over the network. For the serialization as an UINT8 Array two different Transformers are supported, as defined in [TPS_SYST_02294] and [TPS_SYST_02295].

[TPS_SYST_02294] Serialization of ServiceInterfaces using ComBasedTransformer ⌈If the ComBasedTransformer is used to serialize the members of a ServiceInterface, then

- the SenderReceiverToSignalGroupMapping is used to map the VariableDataPrototype that represents an Event or Field Notifier to a SystemSignalGroup. Please note that the datatype of an Event is a Structure as described above. Each primitive member of this Structure is mapped by the SenderRecRecordElementMapping to a SystemSignal in the SystemSignalGroup. The SystemSignalGroup is mapped as ISignalGroup into an ISignalIPdu that is transported over the network.
- the serialization of Methods, Field Setters, Field Getters by the ComBasedTransformer is not supported.

⌋

[TPS_SYST_02295] Serialization of ServiceInterfaces using SomeipTransformer ⌈If the SomeipTransformer is used to serialize the members of a ServiceInterface, then

- the SenderReceiverToSignalMapping is used to map the VariableDataPrototype that represents the Event or Field Notifier to a single SystemSignal. The SystemSignal is mapped as an ISignal into an ISignalIPdu that is transported over the network.
- the ClientServerToSignalMapping is used to map the ClientServerOperation that represents the Method or Field Setter or Field Getter to a Call-SystemSignal and to a Return-SystemSignal. Both SystemSignals are mapped as ISignals into dedicated ISignalIPdus that are transported over the network.
- the SenderReceiverToSignalMapping is used to map the VariableDataPrototype that represents the “fire & forget” method with data to a SystemSignal. The SystemSignal is mapped as ISignal into an ISignalIPdu that is transported over the network. The messageType in the SOMEIPTransformationISignalProps that is aggregated by the ISignal shall be set to requestNoReturn.
- the TriggerToSignalMapping is used to map the Trigger that represents the “fire & forget” method without data to a SystemSignal. The SystemSignal is mapped as ISignal into an ISignalIPdu that is transported over the network. The messageType in the SOMEIPTransformationISignalProps that is aggregated by the ISignal shall be set to requestNoReturn.

⌋

The ServiceInterfaces itself are represented as ServiceInstances in the System Description. The ProvidedServiceInstance is used to describe that a specific instance of a ServiceInterface is provided on an ApplicationEndpoint. The ConsumedServiceInstance is used to describe that a search for a specific instance of a ServiceInterface is executed on an ApplicationEndpoint.

The Pdus that represent the elements of the ServiceInterface are attached to the ServiceInstances via PduActivationRoutingGroups.

Please note that the Pdus that represent the Methods, “fire & forget” methods, Field Setter and Field Getter are assigned to the ServiceInstance in a methodActivationRoutingGroup since they are activated by the SD module as soon as the Service is offered.

The Pdus that represent the Events and Field Notifiers are assigned to EventHandlers on the provided side as pduActivationRoutingGroups or to ConsumedEventGroups on the receiver side as pduActivationRoutingGroups.

[TPS_SYST_02296] eventGroupControlType of a unicast Event ⌈If the Pdu represents an Event that is transmitted or received over unicast then the eventGroupControlType attribute of the PduActivationRoutingGroup that refers the Pdu shall be set to activationUnicast.⌋

[TPS_SYST_02297] eventGroupControlType of a multicast Event ⌈If the Pdu represents an Event that is transmitted or received over multicast then the eventGroupControlType attribute of the PduActivationRoutingGroup that refers the Pdu shall be set to activationMulticast.⌋

[TPS_SYST_02298] eventGroupControlType of a unicast Field ⌈If the Pdu represents a Field Notifier that is transmitted or received over unicast then either:

- two PduActivationRoutingGroups shall be used where:
  - the eventGroupControlType attribute of the PduActivationRoutingGroup that refers the Pdu is set to activationUnicast.
  - the eventGroupControlType attribute of the PduActivationRoutingGroup that refers the Pdu is set to triggerUnicast.
- or one PduActivationRoutingGroup shall be used where the eventGroupControlType attribute of the PduActivationRoutingGroup that refers the Pdu shall be set to activationAndTriggerUnicast.

⌋

With this approach it is ensured that the current value of the Field is sent back immediately to the subscriber in an event-like notification pattern as soon as the subscription to the field becomes effective (TriggerUnicast). Additional update notifications will be sent to subscribers over IP Unicast whenever the value of the field gets updated (ActivationUnicast). Please note that the immediate transmission of the current value to the subscriber of the `Field` value is supported over IP Unicast only.

Apart of the immediate transmission (TriggerUnicast) the server may choose to transmit further notifications over IP Multicast in case that the `multicastThreshold` is set to a value >= 1. In this case a `PduActivationRoutingGroup` shall be used that has the `eventGroupControlType` attribute set to `activationMulticast`.

The following listing shows an example for a `ProvidedServiceInstance` of the *RadarService*.

Listing 10.4: Example for a ProvidedServiceInstance

11 Software Cluster

11.1 Big Picture

Among the different architecture approaches implemented in automotive software solutions, the so-called *domain architecture* is characterized by the existence of so-called *domain controllers*[1] that act as a "manager" for a specific domain (e.g. powertrain, body, chassis) in automotive software.

Domain controllers are connected to each other via a backbone communication bus and also typically utilize various communication buses to communicate with domain-specific controller ECUs. The concept of *domain controllers* is sketched in Figure 11.1.

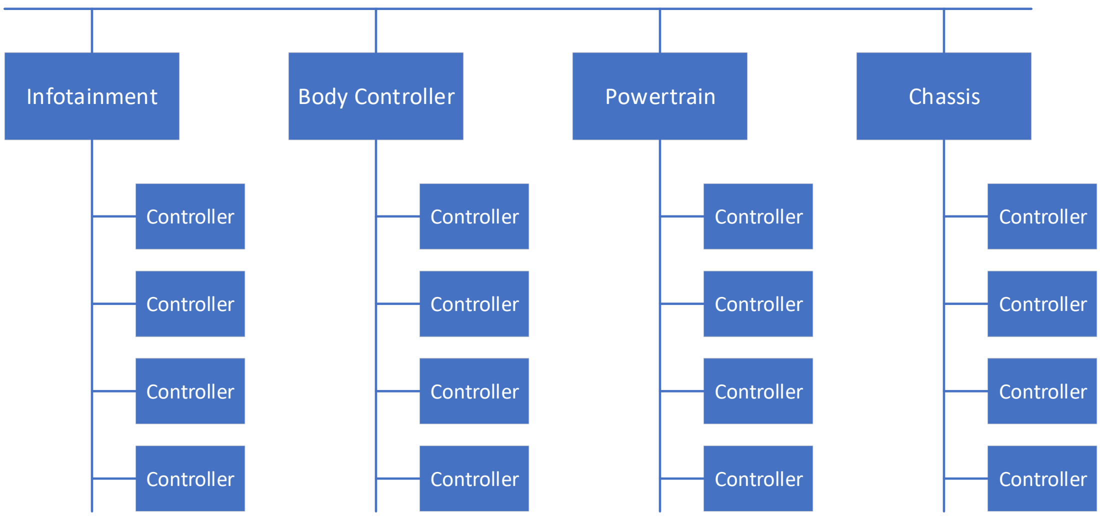

Figure 11.1: Sketch of an automotive *domain controller* architecture

A consequence of the *domain controller* concept is that the individual *domain controller* ECUs become very complex and typically host several thousand software-components. As far as the methodology on the *AUTOSAR classic platform* is concerned[2], the ECU needs to be fully integrated **before** the generation of the RTE can be started.

The integration involves not only the consistent configuration of all basic software modules but also requires the creation of connections between the application software and the service software-components that represent the service layer of the AUTOSAR basic software.

This leads to the following list of issues:

- Generation of the RTE takes a long time.

[1]This term is inspired by the existence of functional domains inside a typical vehicle, not to be confused with the definition of the term ("central authentication server") in general computer science.
[2]The workflow on the *AUTOSAR classic platform* is centered around the idea to build a complete executable image for each ECU in one step

- Single failures can block the entire integration process.
- Build times become very high.

Please note that similar problems occur in any kind of software architecture which centralizes software functionality in specific ECUs, e.g. zone Controllers.

In response to the increase in complexity, integration time, possible mistakes, and build time, the software on such complex ECUs can be structurally decomposed into so-called `Software Cluster`s of arbitrary complexity.

A `Software Cluster` can be developed, integrated against, and built independently of the surrounding host system on the enclosing ECU. After completion of the development workflow, a `Software Cluster` can be deployed to its host ECU independently, i.e. the deployment of such a `Software Cluster` does not require the entire ECU to be re-programmed.

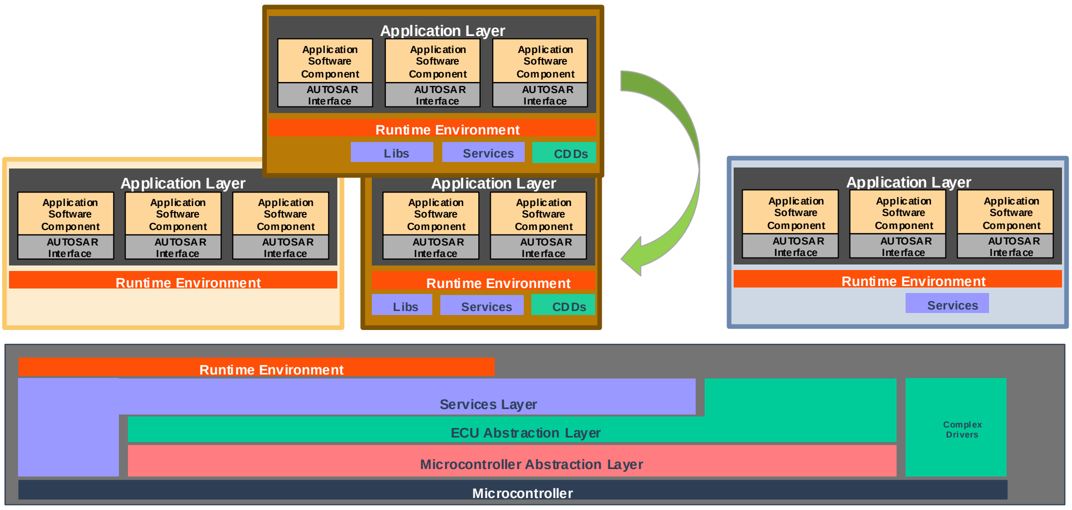

Figure 11.2: Replace an existing `Software Cluster` without reprogramming the entire ECU

In other words, the rest of the software on the respective ECU can be left unchanged and is kept binary identical if a given `Software Cluster` is flashed onto the respective ECU.

[TPS_SYST_02315] Definition of a software cluster on the *AUTOSAR classic platform*

Upstream requirements: RS_SYST_00060

⌈On the *AUTOSAR classic platform*, a `Software Cluster` is represented by meta-class `CpSoftwareCluster`. A `CpSoftwareCluster` is defined by references to a collection of either

- CompositionSwComponentType in the role swComposition, in this case the CpSoftwareCluster is described as a re-usable asset out of the context of a concrete System.
- SwComponentPrototype in the role swComponent, in the case the CpSoftwareCluster is defined in the context of a System.

⌋

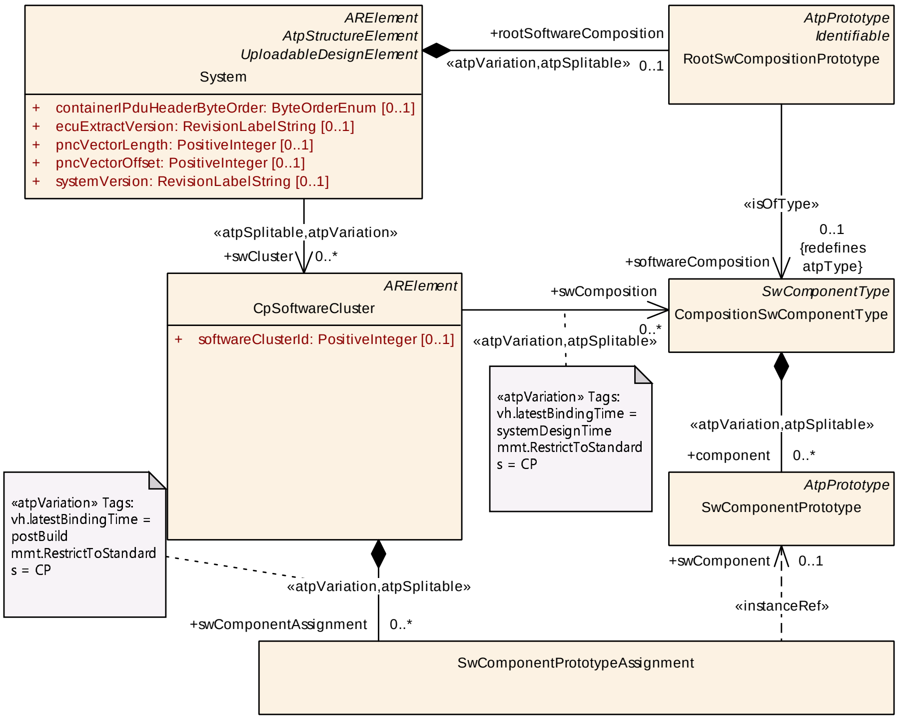

Figure 11.3: Modeling of the CpSoftwareCluster

[TPS_SYST_02316] Semantics of meta-class SwComponentPrototypeAssignment

Upstream requirements: RS_SYST_00060

⌈Meta-class SwComponentPrototypeAssignment as well as its aggregation at CpSoftwareCluster in the role swComponentAssignment supports the definition of a variation point in the relation between CpSoftwareCluster and SwComponentPrototype.⌋

Class	**CpSoftwareCluster**			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster			
Note	This meta class provides the ability to define a CP Software Cluster. Each CP Software Cluster can be integrated and build individually. It defines the sub-set of hierarchical tree(s) of Software Components belonging to this CP Software Cluster. Resources required or provided by this CP Software Cluster are given in the according mappings. **Tags:** atp.recommendedPackage=CpSoftwareClusters			
Base	*ARElement*, *ARObject*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *Packageable Element*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
softwareCluster Id	PositiveInteger	0..1	attr	This attribute represents the value of the id of the corresponding CP software cluster.
swComponent Assignment	SwComponent PrototypeAssignment	*	aggr	This is the collection of SwComponentPrototype Assignments **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=swComponentAssignment, swComponent Assignment.variationPoint.shortLabel vh.latestBindingTime=postBuild
swComposition	CompositionSw ComponentType	*	ref	Software Components in the context of a CompositionSw ComponentType belonging to this CP Software Cluster. This reference can be used to describe the belonging SWCs when the CP Software Cluster is described out of the context of a System, e.g. reusable CP Software Cluster. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=swComposition.compositionSwComponent Type, swComposition.variationPoint.shortLabel vh.latestBindingTime=systemDesignTime

Table 11.1: CpSoftwareCluster

Class	**SwComponentPrototypeAssignment**			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster			
Note	This meta-class is only required to allow for the variant modeling of an instanceRef.			
Base	*ARObject*			
Aggregated by	CpSoftwareCluster.swComponentAssignment			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
swComponent	SwComponent Prototype	0..1	iref	hierarchical tree(s) of Software Components belonging to this CP Software Cluster. This reference is used to describe the belonging SWCs if the CP Software Cluster is described in the context of a System, **InstanceRef implemented by:** ComponentInSystem InstanceRef

Table 11.2: SwComponentPrototypeAssignment

[TPS_SYST_02317] References from CpSoftwareCluster to CompositionSwComponentType and SwComponentPrototype

Upstream requirements: RS_SYST_00060

⌈The usage of the reference CpSoftwareCluster.swComposition shall eventually be replaced by the swComponentAssignment aggregation when the SwComponentPrototypes referenced by the CpSoftwareCluster (via the role swComponentAssignment) are integrated into a concrete Ecu Extract.⌋

[constr_5327] Existence of attribute CpSoftwareCluster.category

Imposition time: IT_SwCluSysDesc

⌈For each CpSoftwareCluster, attribute category shall exist.⌋

[constr_5335] CpSoftwareCluster.softwareClusterId shall be unique in the scope of an EcuInstance

Imposition time: IT_SwCluSysDesc

⌈The softwareClusterId shall be unique for each CpSoftwareCluster that is mapped to the same EcuInstance with the CpSoftwareClusterToEcuInstanceMapping.⌋

[constr_5336] Existence of CpSoftwareCluster.softwareClusterId

Imposition time: IT_SwCluSysDesc

⌈For each CpSoftwareCluster, attribute softwareClusterId shall exist.⌋

Class	**CompositionSwComponentType**			
Package	M2::AUTOSARTemplates::SWComponentTemplate::Composition			
Note	A CompositionSwComponentType aggregates SwComponentPrototypes (that in turn are typed by SwComponentTypes) as well as SwConnectors for primarily connecting SwComponentPrototypes among each others and towards the surface of the CompositionSwComponentType. By this means, a hierarchical structures of software-components can be created. **Tags:** atp.recommendedPackage=SwComponentTypes			
Base	*ARElement*, *ARObject*, *AtpBlueprint*, *AtpBlueprintable*, *AtpClassifier*, *AtpType*, *CollectableElement*, *Identifiable*, *MultilanguageReferrable*, *PackageableElement*, *Referrable*, *SwComponentType*			
Aggregated by	ARPackage.element			
Attribute	***Type***	***Mult.***	***Kind***	***Note***

▽

△

Class	CompositionSwComponentType			
component	SwComponent Prototype	*	aggr	The instantiated components that are part of this composition. The aggregation of SwComponentPrototype is subject to variability with the purpose to support the conditional existence of a SwComponentPrototype. Please be aware: if the conditional existence of SwComponentPrototypes is resolved post-build, the deselected SwComponentPrototypes are still contained in the ECUs build but the instances are inactive in that they are not scheduled by the RTE. The aggregation is marked as atpSplitable in order to allow the addition of service components to the ECU extract during the ECU integration. The use case for having 0 components owned by the CompositionSwComponentType could be to deliver an empty CompositionSwComponentType to e.g. a supplier for filling the internal structure. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=component.shortName, component.variation Point.shortLabel vh.latestBindingTime=postBuild
connector	SwConnector	*	aggr	SwConnectors have the principal ability to establish a connection among PortPrototypes. They can have many roles in the context of a CompositionSwComponentType. Details are refined by subclasses. The aggregation of SwConnectors is subject to variability with the purpose to support variant data flow. The aggregation is marked as atpSplitable in order to allow the extension of the ECU extract with AssemblySwConnectors between ApplicationSwComponentTypes and ServiceSwComponentTypes during the ECU integration. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=connector.shortName, connector.variation Point.shortLabel vh.latestBindingTime=postBuild
constantValue Mapping	ConstantSpecification MappingSet	*	ref	Reference to the ConstantSpecificationMapping to be applied for initValues of PPortComSpecs and RPortComSpec. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=constantValueMapping

▽

△

Class	CompositionSwComponentType			
dataType Mapping	DataTypeMappingSet	*	ref	Reference to the DataTypeMappingSet to be applied for the used ApplicationDataTypes in PortInterfaces. Background: when developing subsystems it may happen that ApplicationDataTypes are used on the surface of CompositionSwComponentTypes. In this case it would be reasonable to be able to also provide the intended mapping to the ImplementationDataTypes. However, this mapping shall be informal and not technically binding for the implementors mainly because the RTE generator is not concerned about the CompositionSwComponentTypes. Rationale: if the mapping of ApplicationDataTypes on the delegated and inner PortPrototype matches then the mapping to ImplementationDataTypes is not impacting compatibility. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=dataTypeMapping
instantiation RTEEventProps	InstantiationRTEEvent Props	*	aggr	This allows to define instantiation specific properties for RTE Events, in particular for instance specific scheduling. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=instantiationRTEEventProps.shortLabel, instantiationRTEEventProps.variationPoint.shortLabel vh.latestBindingTime=codeGenerationTime
physical Dimension Mapping	PhysicalDimension MappingSet	0..1	ref	This reference identifies the PhysicalDimensionMappingSet that is applicable in the context of the enclosing CompositionSwComponentType. The PhysicalDimensionMappings contained in the PhysicalDimensionMappingSet shall be taken into account for the assessment of the compatibility of PhysicalDimensions in the context of creation of a PortInterfaceMapping in the scope of the CompositionSwComponentType.

Table 11.3: CompositionSwComponentType

Class	SwComponentPrototype			
Package	M2::AUTOSARTemplates::SWComponentTemplate::Composition

[TPS_SYST_02318] Membership in System

Upstream requirements: RS_SYST_00060

⌈The membership of a given CpSoftwareCluster can be formalized by means of the reference System.swCluster.⌋

[TPS_SYST_02319] Semantics of attribute CpSoftwareCluster.category

Upstream requirements: RS_SYST_00060

⌈The following values for attribute CpSoftwareCluster.category are standardized by AUTOSAR:

- **HOST_SOFTWARE_CLUSTER**: the CpSoftwareCluster that contains the major part of the basic-software stack, especially micro-controller-dependent modules including the operating system.
- **APPLICATION_SOFTWARE_CLUSTER**: the CpSoftwareCluster represents application-level functionality conceptually located on top of the CpSoftwareCluster of category HOST_SOFTWARE_CLUSTER.

⌋

[constr_5176] Existence of CpSoftwareCluster of category HOST_SOFTWARE_CLUSTER on one EcuInstance

Imposition time: IT_SwCluSysDesc

⌈On each EcuInstance, exactly one CpSoftwareCluster of category HOST_SOFTWARE_CLUSTER shall exist.⌋

[constr_5177] Validity of reference CpSoftwareClusterToEcuInstanceMapping.swCluster

Imposition time: IT_SwCluSysDesc

⌈A CpSoftwareClusterToEcuInstanceMapping that references a given CpSoftwareCluster in the role CpSoftwareClusterToEcuInstanceMapping.swCluster shall be aggregated by the same System (in the role System.mapping.swMapping) that also refers to the referenced CpSoftwareCluster in the role System.swCluster.⌋

The interaction of Software Clusters with the service layer of the basic software stack requires the definition of Software Cluster Resources (see Figure 11.4). Software Clusters declare required and provided Software Cluster Resources that can be satisfied from a central resource pool.

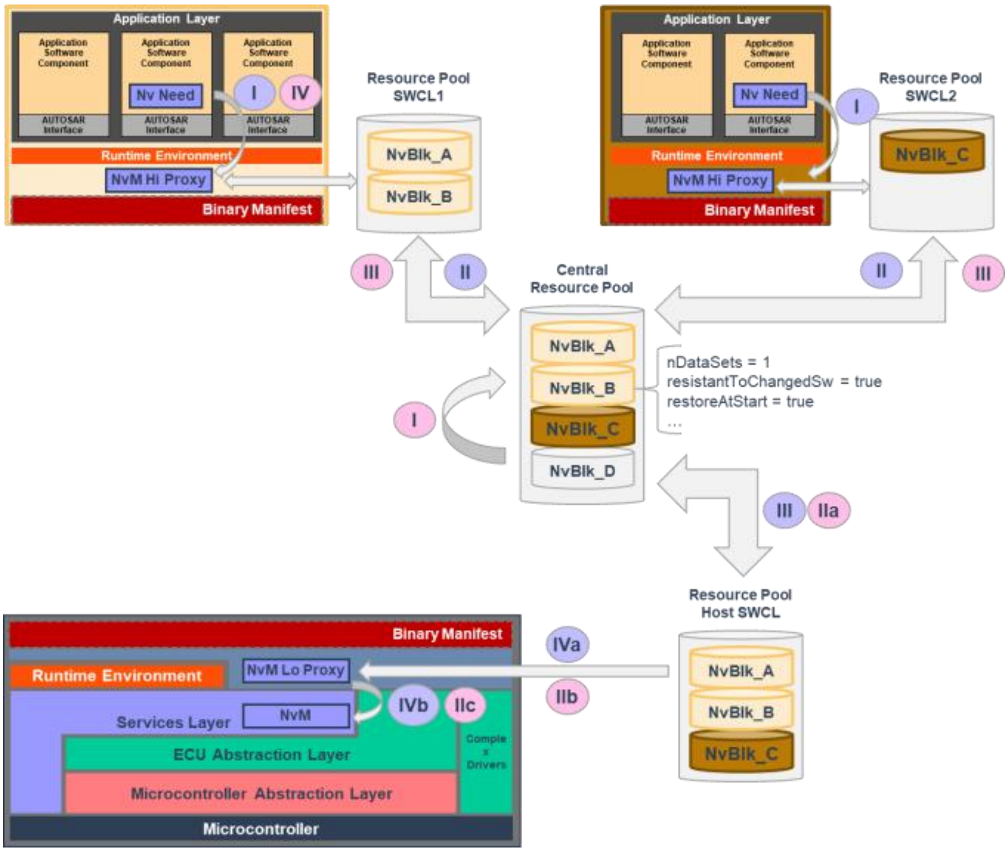

Figure 11.4: Example usage of Software Cluster Resources

Details regarding the Software Cluster Resource are described in section 11.2.

There are in principle two different approaches to connect Software Clusters with each other:

Off-board In this case the connection is created by a software tool on the basis of the binary image of the Software Cluster and modeled information that formally describes the so-called Software Cluster Binary Manifest. The content of the model of the Software Cluster Binary Manifest represents meta-data of the actual connection information. The main benefit of this approach is that the meta-data does not have to be stored on-board, i.e. on the target Ecu.

On-board In this case the connection is created by software running on the target Ecu during the reprogramming phase on the basis of meta-data of the connection endpoints (semantically identical to the content of the model of the respective Software Cluster Binary Manifest). The connection data is stored in modifiable memory. The meta-data content is stored on device, and the required memory markup for this aspect needs to be taken into account for Ecu design.

It is important to understand that the Software Cluster and the corresponding Software Cluster Binary Manifest are associated with different steps in the development workflow. A Software Cluster represents a design model element while the Software Cluster Binary Manifest is a derived information used to support a downstream integration phase for defining an off-board connection.

This relation leads to modeling decisions, such that elements of the Software Cluster Binary Manifest can only reference elements of the Software Cluster, but can't be aggregated by them.

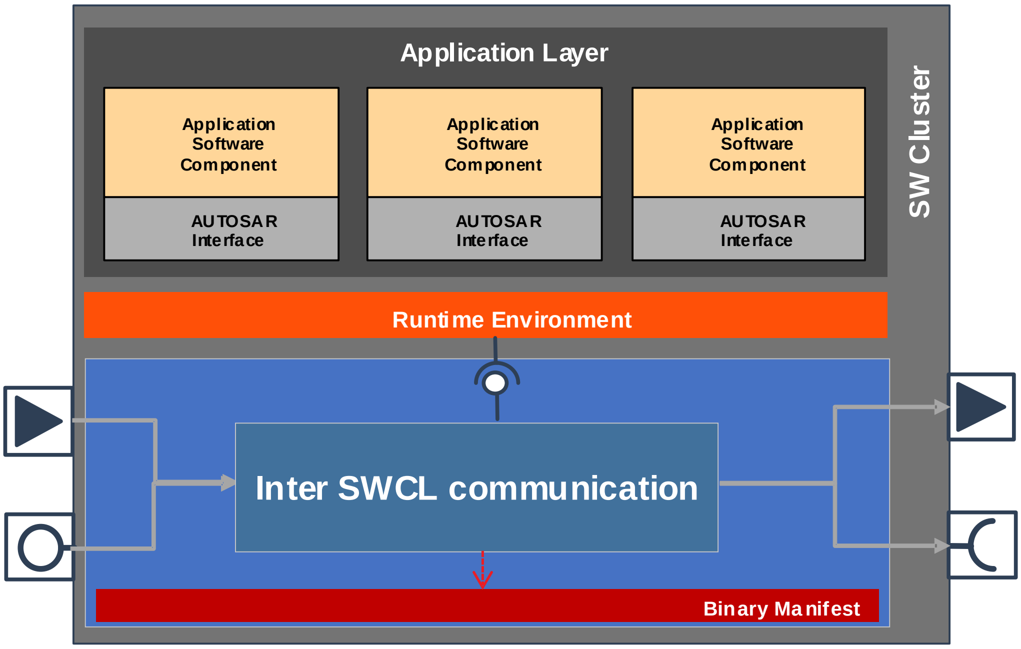

Figure 11.5: Software Cluster Binary Manifest of a single Software Cluster

The Software Cluster Binary Manifest is described in more detail in section 11.3.

The mapping of Software Clusters to EcuInstance and ApplicationPartition is described in section 5.5.

11.2 Software Cluster Resources

A CpSoftwareCluster is able to provide CpSoftwareClusterResources that will be accessed by other CpSoftwareClusters. At the same time a CpSoftwareCluster may require CpSoftwareClusterResources from other CpSoftwareClusters to operate the software that belongs to the CpSoftwareCluster.

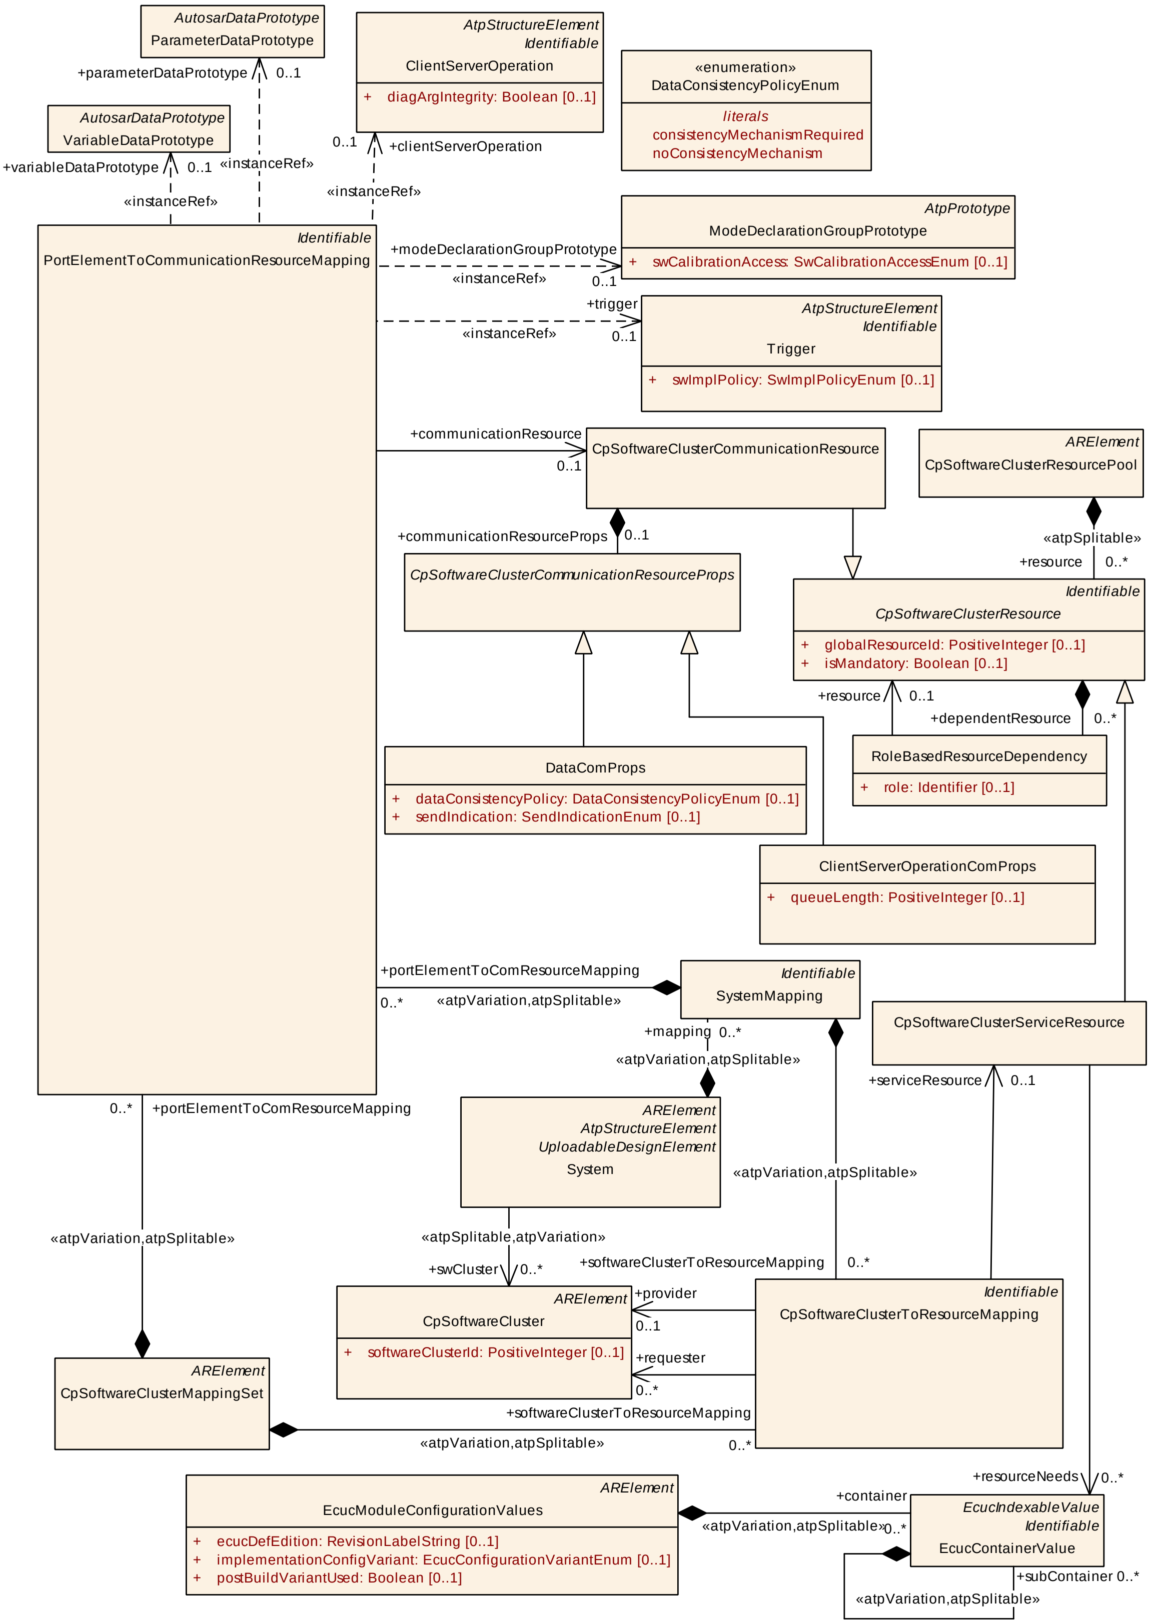

Figure 11.6: Software Cluster Resources

[TPS_SYST_02320] Kinds of CpSoftwareClusterResources

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈There are two kinds of CpSoftwareClusterResources:

- CpSoftwareClusterCommunicationResource that relates to a port based communication on VFB level, for instance to a sender-receiver communication or client-server communication,
- CpSoftwareClusterServiceResource that relates to the Basic Software, for instance to a NvBlock.

Attribute	*Type*	*Mult.*	*Kind*	*Note*
resourceNeeds	EcucContainerValue	*	ref	Refernce(s) to one or multiple EcucContainerValue(s) qualifying the characteristics of the resource.

Table 11.14: CpSoftwareClusterServiceResource

[constr_5181] Existence of attribute CpSoftwareClusterServiceResource.category

Imposition time: IT_ResPool

⌈For each CpSoftwareClusterServiceResource, attribute category shall exist.⌋

The applicable values of CpSoftwareClusterServiceResource.category are defined in the document "Software Cluster Connection".

CpSoftwareClusterResources are collected in CpSoftwareClusterResourcePools and are assigned to a CpSoftwareCluster in different ways as defined by the following specification items:

[TPS_SYST_02321] Assignment of CpSoftwareClusterCommunicationResources to CpSoftwareClusters in the context of a SwComponentPrototype

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈In case that a SwComponentPrototype is defined in the context of a System and this SwComponentPrototype is assigned to the CpSoftwareCluster with the CpSoftwareCluster.swComponentAssignment and the SwComponentPrototype defines an interface of the CpSoftwareCluster then the PortElementToCommunicationResourceMapping aggregated by a SystemMapping maps the CpSoftwareClusterCommunicationResource to an element of a PortInterface used in the context of a PortPrototype in the SwComponentPrototype.

If the PortPrototype of the SwComponentPrototype is a PPortPrototype then the CpSoftwareClusterCommunicationResource is provided by the CpSoftwareCluster.

If the PortPrototype of the SwComponentPrototype is a RPortPrototype then the CpSoftwareClusterCommunicationResource is required by the CpSoftwareCluster.⌋

[TPS_SYST_02345] Assignment of CpSoftwareClusterCommunicationResources to CpSoftwareClusters in the context of a SwComponentType

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈In case that a CompositionSwComponentType is defined and is assigned to the CpSoftwareCluster with the CpSoftwareCluster.swComposition and this SwComponentType defines an interface of the CpSoftwareCluster then the PortElementToCommunicationResourceMapping that is aggregated by a CpSoftwareClusterMappingSet maps the CpSoftwareClusterCommunicationResource to an element of a PortInterface used in the context of a PortPrototype of a CompositionSwComponentType.

If the PortPrototype of the CompositionSwComponentType is a PPortPrototype then the CpSoftwareClusterCommunicationResource is provided by the CpSoftwareCluster.

If the PortPrototype of the CompositionSwComponentType is a RPortPrototype then the CpSoftwareClusterCommunicationResource is required by the CpSoftwareCluster.⌋

Class	**PortElementToCommunicationResourceMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate			
Note	This meta class maps a communication resource to CP Software Clusters. In this case the kind of Port Prototype specified whether the Software Cluster has to provide or to require the resource.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	CpSoftwareClusterMappingSet.portElementToComResourceMapping, SystemMapping.portElementToComResourceMapping			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
clientServerOperation	ClientServerOperation	0..1	iref	ClientServerOperation instance qualifying the communication resource **InstanceRef implemented by:** OperationInSystemInstanceRef
communicationResource	CpSoftwareClusterCommunicationResource	0..1	ref	Communication resource for which the mapping applies.
modeDeclarationGroupPrototype	ModeDeclarationGroupPrototype	0..1	iref	ModeDeclarationGroupPrototype instance qualifying the communication resource **InstanceRef implemented by:** ModeDeclarationGroupPrototypeInSystemInstanceRef
parameterDataPrototype	ParameterDataPrototype	0..1	iref	ParameterDataPrototype instance qualifying the communication resource. **InstanceRef implemented by:** ParameterDataPrototypeInSystemInstanceRef
trigger	Trigger	0..1	iref	Trigger instance qualifying the communication resource. **InstanceRef implemented by:** TriggerInSystemInstanceRef
variableDataPrototype	VariableDataPrototype	0..1	iref	VariableDataPrototype instance qualifying the communication resource **InstanceRef implemented by:** VariableDataPrototypeInSystemInstanceRef

Table 11.15: PortElementToCommunicationResourceMapping

Please note that the assignment of CpSoftwareClusterCommunicationResources to CpSoftwareClusters in the context of a SwComponentTypes as described by [TPS_SYST_02345] shall only be used in an early stage of the Methodology if the System with the RootSwCompositionPrototype and all included SystemMappings is not available yet.

In this case not all context references in the «instanceRef» of PortElementToCommunicationResourceMapping can be used since the SwComponentPrototype is not available yet.

[TPS_SYST_02322] PortElementToCommunicationResourceMapping aggregated by SystemMapping supersedes PortElementToCommunicationResourceMapping aggregated by CpSoftwareClusterMappingSet

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈If a PortElementToCommunicationResourceMapping that is aggregated by the SystemMapping and a PortElementToCommunicationResourceMapping that is aggregated by the CpSoftwareClusterMappingSet exist at the same time and both reference the same element in the same PortPrototype then the PortElementToCommunicationResourceMapping that is aggregated by the SystemMapping supersedes the PortElementToCommunicationResourceMapping that is aggregated by the CpSoftwareClusterMappingSet.⌋

[constr_5329] SynchronousServerCallPoints for cross cluster communication are not supported

Imposition time: IT_SwCluSysDesc

⌈A ClientServerOperation in the context of PortPrototype which is referenced by a PortElementToCommunicationResourceMapping in the role clientServerOperation is not allowed

- to be referenced by a SynchronousServerCallPoint.operation or
- to be connected to another ClientServerOperation in the context of a PortPrototype that in turn is referenced by SynchronousServerCallPoint.operation

⌋

[constr_5182] PRPortPrototypes are excluded as CpSoftwareCluster interfaces

Imposition time: IT_SwCluSysDesc

⌈A CpSoftwareClusterCommunicationResource is not allowed to be mapped by a PortElementToCommunicationResourceMapping to an element of a PortInterface in the context of a PRPortPrototype.⌋

Please note that it is allowed that a PPortPrototype that is referenced by a PortElementToCommunicationResourceMapping is allowed to be connected via a DelegationSwConnector to a PRPortPrototype.

[constr_5183] PortElementToCommunicationResourceMapping shall reference exactly one element of a PortInterface

Imposition time: IT_SwCluSysDesc

⌈For any given PortElementToCommunicationResourceMapping, either the reference

- parameterDataPrototype or
- modeDeclarationGroupPrototype or
- trigger or
- clientServerOperation or
- variableDataPrototype

shall exist.⌋

[TPS_SYST_02323] Assignment of CpSoftwareClusterServiceResources to CpSoftwareClusters

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈A CpSoftwareClusterServiceResource is mapped to CpSoftwareCluster with a CpSoftwareClusterToResourceMapping.⌋

Class	**CpSoftwareClusterToResourceMapping**			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster			
Note	This meta class maps a service resource to CP Software Clusters. By this mapping it's specified whether the Software Cluster has to provide or to require the resource.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	CpSoftwareClusterMappingSet.softwareClusterToResourceMapping, SystemMapping.softwareClusterToResourceMapping			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
provider	CpSoftwareCluster	0..1	ref	CP Software Cluster providing the resource
requester	CpSoftwareCluster	*	ref	CP Software Cluster requesting the resource
serviceResource	CpSoftwareClusterServiceResource	0..1	ref	Service resource for which the mapping applies.

Table 11.16: CpSoftwareClusterToResourceMapping

[TPS_SYST_02324] CpSoftwareClusterServiceResource provided by the CpSoftwareCluster

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈A CpSoftwareClusterResource is provided by a CpSoftwareCluster if a CpSoftwareClusterToResourceMapping exists that

- references the CpSoftwareClusterResource in the role serviceResource and
- references the CpSoftwareCluster in the role provider

⌋

[TPS_SYST_02325] CpSoftwareClusterServiceResource required by the CpSoftwareCluster

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈A CpSoftwareClusterResource is required by a CpSoftwareCluster if a CpSoftwareClusterToResourceMapping exists that

- references the CpSoftwareClusterResource in the role serviceResource and
- references the CpSoftwareCluster in the role requester.

⌋

[constr_5184] CpSoftwareClusterServiceResource can be provided only once on an EcuInstance

Imposition time: IT_SwCluSysDesc

⌈A CpSoftwareClusterServiceResource shall not be mapped by several CpSoftwareClusterToResourceMappings to CpSoftwareClusters in the provider role if the CpSoftwareClusters are mapped to the same EcuInstance by CpSoftwareClusterToEcuInstanceMappings.⌋

[TPS_SYST_02326] Aggregation possibilities of CpSoftwareClusterToResourceMapping

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈The CpSoftwareClusterToResourceMapping can be aggregated by CpSoftwareClusterMappingSet and by SystemMapping.

- CpSoftwareClusterMappingSet.softwareClusterToResourceMapping can be used in an early stage of the Methodology if the System with the RootSwCompositionPrototype and all included SystemMappings is not available yet.
- SystemMapping.softwareClusterToResourceMapping can be used in a later stage of Methodology if the System with the RootSwCompositionPrototype and all included SystemMappings is available.

⌋

[TPS_SYST_02346] CpSoftwareClusterToResourceMapping aggregated by SystemMapping supersedes CpSoftwareClusterToResourceMapping aggregated by CpSoftwareClusterMappingSet

Upstream requirements: RS_SYST_00060, RS_SYST_00062

⌈If a CpSoftwareClusterToResourceMapping that is aggregated by the SystemMapping and a CpSoftwareClusterToResourceMapping that is aggregated by the CpSoftwareClusterMappingSet exist at the same time and both are mapping the same CpSoftwareClusterServiceResource to the same CpSoftwareCluster then the CpSoftwareClusterToResourceMapping that is aggregated by the SystemMapping supersedes the CpSoftwareClusterToResourceMapping that is aggregated by the CpSoftwareClusterMappingSet.⌋

[constr_5360] Cross cluster communication involving NvBlockSwComponentType is not supported

Imposition time: IT_SwCluSysDesc

⌈A PortElementToCommunicationResourceMapping that is referencing a CpSoftwareClusterCommunicationResource in the role communicationResource is not allowed to reference:

- a VariableDataPrototype in the role variableDataPrototype that is defined in the context of a PortPrototype of a NvBlockSwComponentType typed by a NvDataInterface or
- a VariableDataPrototype in the role variableDataPrototype which is connected to another VariableDataPrototype that is defined in the context of a PortPrototype of a NvBlockSwComponentType and typed by a NvDataInterface or
- a ClientServerOperation in the role clientServerOperation that is defined in the context of a PortPrototype of a NvBlockSwComponentType typed by a ClientServerInterface or
- a ClientServerOperation in the role clientServerOperation which is connected to another ClientServerOperation that is defined in the context of a PortPrototype of a NvBlockSwComponentType typed by a ClientServerInterface

⌋

11.3 Software Cluster Binary Manifest

[TPS_SYST_02327] Role of the Software Cluster Binary Manifest

Upstream requirements: RS_SYST_00061

⌈The modeling of the Software Cluster Binary Manifest allows for the formal definition of how a given Software Cluster interacts with the environment. This formal model is **only relevant for the creation of an off-board connection** between Software Clusters.

The core characteristics of the model of a Software Cluster Binary Manifest are:

- The model of a Software Cluster Binary Manifest is created during the Software Cluster's build because it has to store information (e.g. data and function addresses, ID values for the interaction with basic software services) that only become available during build time.
- The model of a Software Cluster Binary Manifest uses guarding information (e.g. hash values) to ensure that only compatible resources are connected to each other.

The Software Cluster Binary Manifest is defined on integration level[3].⌋

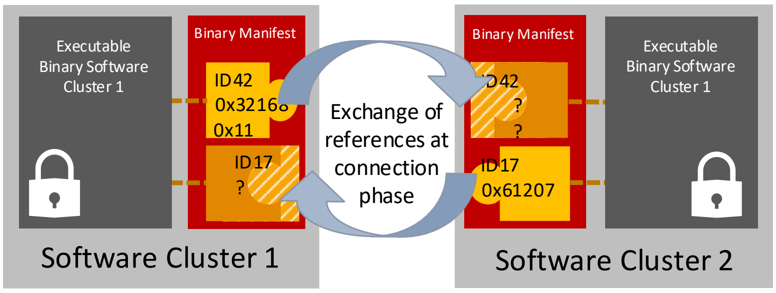

Figure 11.7: Two Software Cluster exchange information in their Software Cluster Binary Manifests.

This means that, at run-time, the Software Cluster Binary Manifest consists of data structures that are partly non-modifiable (to define e.g. meta-data or describe the access to a resource) and partly modifiable (to store the connection information, see Figure 11.7).

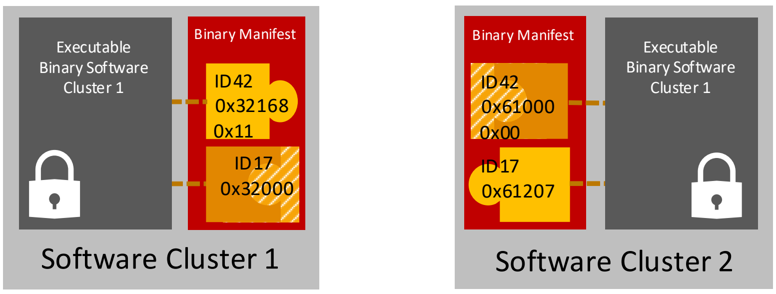

Figure 11.8: Two Software Cluster and their fully-configured Software Cluster Binary Manifests

The missing pieces in the Software Cluster Binary Manifest can be filled by exchanging information at either configuration-time (off-board) or run-time (on-board), see Figure 11.8. The algorithm used to create an off-board connection is identical to the algorithm used to create an on-board connection.

[3]As opposed to design level, on which the actual CpSoftwareCluster exists

The difference ist mainly that the creation of the on-board connection needs the information stored in the model of a Software Cluster Binary Manifest on-board, i.e. a significant amount of on-board storage is required for holding the connection meta-data.

The logical structure of the Software Cluster Binary Manifest is depicted in Figure 11.9

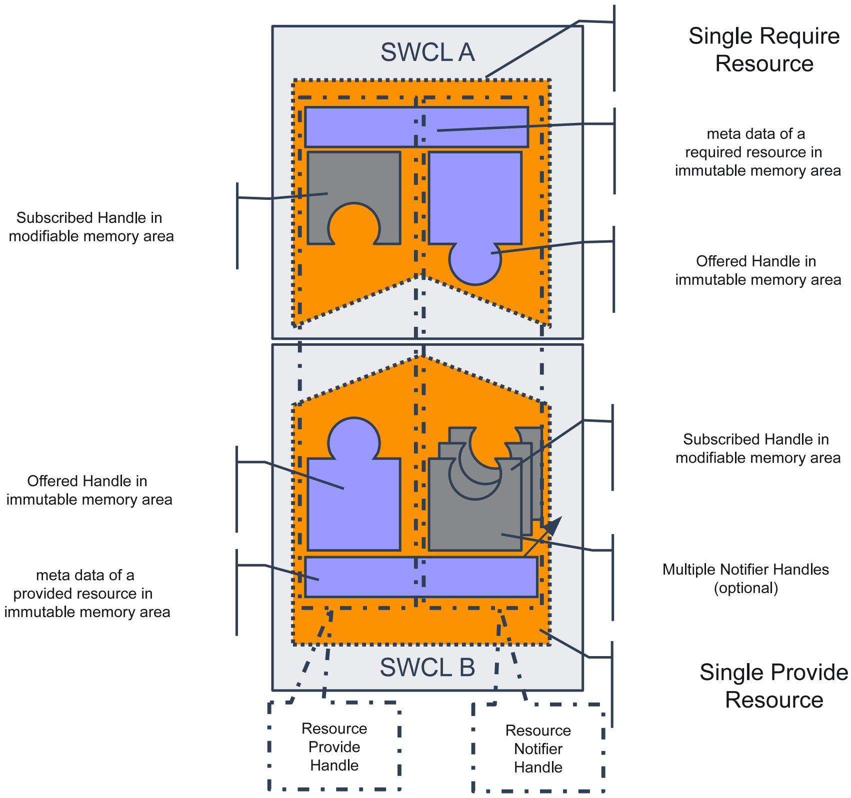

Figure 11.9: Logical structure of the Software Cluster Binary Manifest

[TPS_SYST_02328] Semantics of meta-class CpSoftwareClusterBinaryManifestDescriptor

Upstream requirements: RS_SYST_00061

⌈The existence of the CpSoftwareClusterBinaryManifestDescriptor represents the definition of the model of a Software Cluster Binary Manifest for a given Software Cluster.

Because of this relation, it is necessary that CpSoftwareClusterBinaryManifestDescriptor references the corresponding CpSoftwareCluster instead of being aggregated by it.⌋

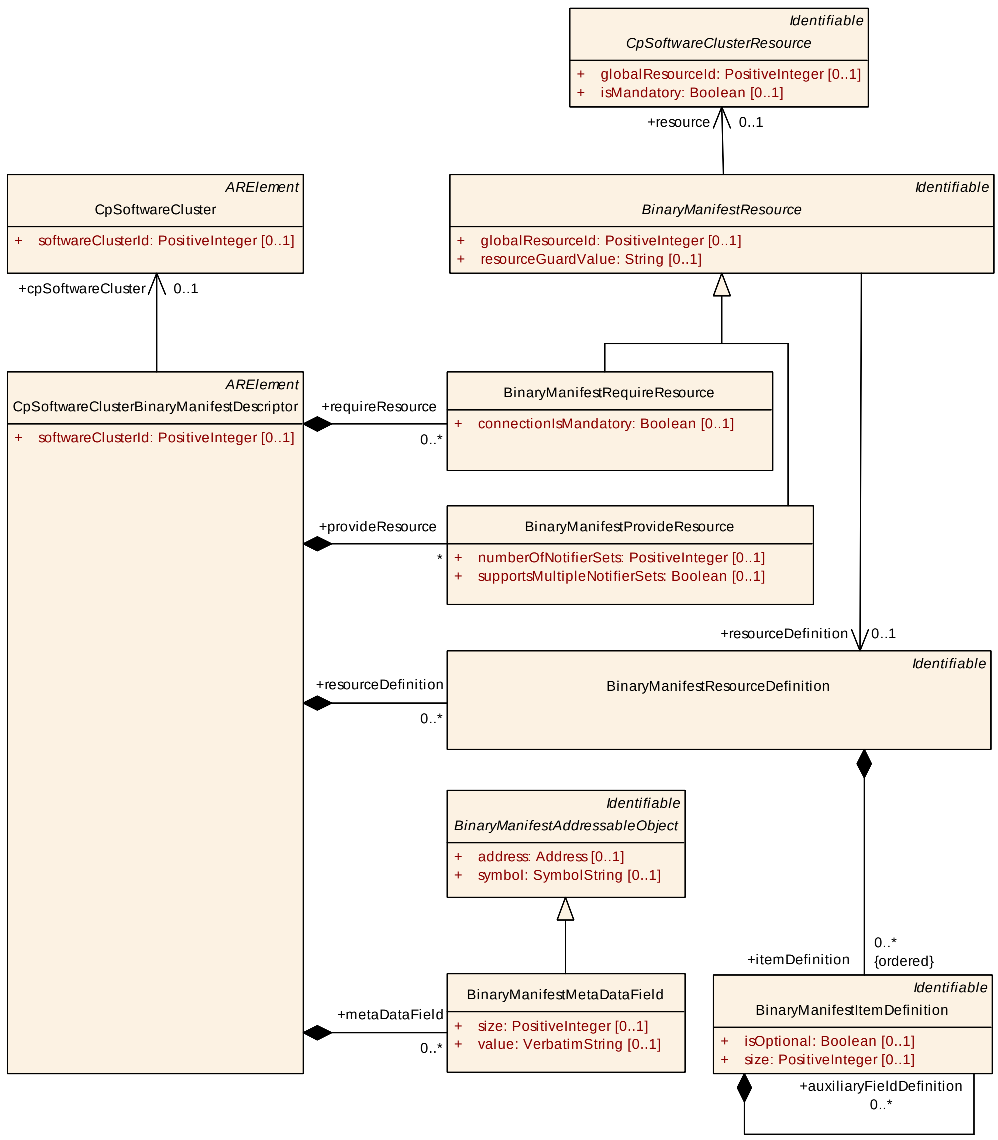

Figure 11.10: Modeling of the Software Cluster Binary Manifest

[TPS_SYST_02329] Provison of a Software Cluster's ID

Upstream requirements: RS_SYST_00061

⌈The ID of a given Software Cluster formalized as CpSoftwareCluster cannot be defined as an attribute of CpSoftwareCluster because the ID represents an integration-level information. Therefore, the ID is provided by means of attribute CpSoftwareClusterBinaryManifestDescriptor.softwareClusterId.⌋

[TPS_SYST_02330] Possible values of attribute CpSoftwareClusterBinaryManifestDescriptor.category

Upstream requirements: RS_SYST_00061

⌈The following values for attribute CpSoftwareCluster.category are standardized by AUTOSAR:

- **HOST_SOFTWARE_CLUSTER**: the CpSoftwareClusterBinaryManifestDescriptor that contains the major part of the basic-software stack, especially micro-controller-dependent modules including the operating system.
- **APPLICATION_SOFTWARE_CLUSTER**: the CpSoftwareClusterBinaryManifestDescriptor represents application-level functionality conceptually located on top of the CpSoftwareCluster of category HOST_SOFTWARE_CLUSTER.
- **SUBSTITUTION_SOFTWARE_CLUSTER**: in this case the CpSoftwareClusterBinaryManifestDescriptor is used for debugging or prototyping purposes.

⌋

Please note that the standardized values of attribute category for CpSoftwareCluster and CpSoftwareClusterBinaryManifestDescriptor differ by the definition of value SUBSTITTION_SOFTWARE_CLUSTER.

This value is not applicable on the "System"-level, but may make sense in the local scope of the deployment configuration of a given CpSoftwareCluster by means of CpSoftwareClusterBinaryManifestDescriptor.

Class	**CpSoftwareClusterBinaryManifestDescriptor**			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class has the ability to act as a hub for all information related to the binary manifest of a given CP software cluster. The manifest is subject to integrator work and therefore not a part of the definition of the CP software cluster itself. **Tags:** atp.recommendedPackage=CpSoftwareClusterBinaryManifestDescriptors

Imposition time: IT_BinObjMetaData

⌈If attribute BinaryManifestItem.auxiliaryField.category is set to value AUXILARY_CONNECTED_SW_CLUSTER_ID then attribute BinaryManifestItem.auxiliaryField.defaultValue shall exist.⌋

[TPS_SYST_02336] Semantics of meta-class BinaryManifestItemDefinition

Upstream requirements: RS_SYST_00061

⌈The purpose of meta-class BinaryManifestItemDefinition is to provide attributes that are shared among all corresponding BinaryManifestItems.⌋

[TPS_SYST_02337] Semantics of aggregation BinaryManifestItemDefinition.auxiliaryFieldDefinition

Upstream requirements: RS_SYST_00061

⌈The aggregation BinaryManifestItemDefinition.auxiliaryFieldDefinition can be used to define structured BinaryManifestItemDefinition.⌋

[TPS_SYST_02338] Relation between BinaryManifestItemDefinition and BinaryManifestItem

Upstream requirements: RS_SYST_00061

⌈The relation between a particular BinaryManifestItemDefinition and a particular BinaryManifestItem is created by

- the **ordered** aggregation of meta-class BinaryManifestItemDefinition at BinaryManifestResource in the role itemDefinition and
- the **ordered** aggregation of meta-class BinaryManifestItem at BinaryManifestResource in the role item.

In other words, the mentioned correspondence is created such that the n^{th} BinaryManifestResourceDefinition.itemDefinition applies to the n^{th} BinaryManifestResource.item.⌋

Class	BinaryManifestItemDefinition			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class provides the ability to define the handle definition or an auxiliary field of a binary manifest resource.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	BinaryManifestItemDefinition.auxiliaryFieldDefinition, BinaryManifestResourceDefinition.itemDefinition			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
auxiliaryField Definition	BinaryManifestItem Definition	*	aggr	This aggregation is used to define structured Binary ManifestItemDefinitions.
isOptional	Boolean	0..1	attr	If true, the handle definition or auxiliary field of a binary manifest resource is optional and may not be used in all BinaryManifestResources referring to this BinaryManifest ResourceDefinition.
size	PositiveInteger	0..1	attr	This attribute provides the ability to specify the size of the enclosing BinaryManifestResourceDefinition.

Table 11.23: BinaryManifestItemDefinition

[constr_5200] Existence of attribute BinaryManifestItemDefinition.category

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestItemDefinition, attribute category shall exist.⌋

[constr_5201] Existence of attribute BinaryManifestItemDefinition.size

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestItemDefinition, attribute size shall exist.⌋

Class	*BinaryManifestAddressableObject* (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class acts as an abstract base class for addressable objects in the context of the binary manifest of a CP software cluster.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Subclasses	BinaryManifestItem, BinaryManifestMetaDataField			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
address	Address	0..1	attr	This attribute specifies the address of the enclosing addressable object.
symbol	SymbolString	0..1	attr	This attribute specifies the symbol of the addressable object.

Table 11.24: BinaryManifestAddressableObject

[TPS_SYST_02339] Standardized values of attribute BinaryManifestAddressableObject.category

Upstream requirements: RS_SYST_00061

⌈The following list of values of attribute BinaryManifestAddressableObject.category is standardized by AUTOSAR:

- PROVIDER_HANDLE: the BinaryManifestAddressableObject is used to store a provider handle.
- NOTIFIER_HANDLE: the BinaryManifestAddressableObject is used to store a notifier handle.
- IMMUTABLE_TABLES_CHECKSUM: the Immutable Tables Checksum is built over all constants of the Software Cluster Binary Manifest which are not changed by the Software Cluster connection step.
- SUBSCRIBED_INTERFACE_VALIDITY_MARKER: the Subscribed Interface Validity Marker indicate that all tables storing subscribed handles are written after the Software Cluster connection step.
- AUXILARY_ACTUAL_NUMBER_NOTIFIER_SETS: the auxiliary field actual number of used notifier sets describes how many of the notifier sets are occupied by connected resources.
- AUXILARY_CONNECTED_SW_CLUSTER_ID: the auxiliary field connected Software Cluster Id holds the Software Cluster Id from which the handle values are taken in case an connection is established.

⌋

Please note that custom values of BinaryManifestAddressableObject.category are supported as long as the custom value is created in a way that it will not clash with standardized values that may be added in the future. Such a name clash can be prevented by using company-specific or project-specific prefixes, suffixes, or infixes in the value.

[TPS_SYST_02340] Semantics of abstract meta-class BinaryManifestItemValue

Upstream requirements: RS_SYST_00061

⌈Sub-classes of abstract meta-class BinaryManifestItemValue can be used to specify **default values** for a BinaryManifestItem.⌋

Class	***BinaryManifestItemValue*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class has the ability to act as an abstract base class for values of binary manifest item.			
Base	*ARObject*

Aggregated by	BinaryManifestItem.defaultValue, BinaryManifestItem.value			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
value	Numerical	0..1	attr	This attribute specifies the actual numerical value to be used in the binary manifest handle.

Table 11.26: BinaryManifestItemNumericalValue

[constr_5202] Existence of attribute BinaryManifestItemNumericalValue.value

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestItemNumericalValue, attribute value shall exist.⌋

[TPS_SYST_02341] Semantics of the aggregation of meta-class BinaryManifestItemPointerValue in the role defaultValue

Upstream requirements: RS_SYST_00061

⌈Meta-class BinaryManifestItemPointerValue is used to provide a default value for a pointer.

This means that the default value consists of the address and the symbol of the target object of the pointer.

In other words, the memory at the BinaryManifestItem.address is filled with the default target address taken from BinaryManifestItemPointerValue.address.⌋

Class	BinaryManifestItemPointerValue			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class has the ability to provide a value for a pointer in the context of a binary manifest item.			
Base	*ARObject*, *BinaryManifestItemValue*			
Aggregated by	BinaryManifestItem.defaultValue, BinaryManifestItem.value			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
address	Address	0..1	attr	This attribute represents the address value of the enclosing pointer value.
symbol	SymbolString	0..1	attr	This attribute represents the symbol associated with the binary manifest handle.

Table 11.27: BinaryManifestItemPointerValue

[constr_5218] Existence of attribute BinaryManifestItemPointerValue.address

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestItemPointerValue, attribute address shall exist.⌋

[constr_5203] Existence of attribute BinaryManifestItemPointerValue.symbol

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestItemPointerValue, attribute symbol shall exist.⌋

[TPS_SYST_02342] Semantics of meta-class BinaryManifestMetaDataField

Upstream requirements: RS_SYST_00061

⌈Meta-class BinaryManifestMetaDataField is used to describe meta-data of a Software Cluster Binary Manifest. This can be achieved by means of the aggregation of BinaryManifestMetaDataField at CpSoftwareClusterBinaryManifestDescriptor in the role metaDataField.

As a part of the Software Cluster Binary Manifest, a BinaryManifestMetaDataField is represented at run-time by a symbol that is located at an address.

On the model level, attribute category can be used to further categorize a specific BinaryManifestMetaDataField.⌋

Class	**BinaryManifestMetaDataField**			
Package	M2::AUTOSARTemplates::SystemTemplate::SoftwareCluster::BinaryManifest			
Note	This meta-class provides the ability to define a meta-data field for the binary manifest descriptor.			
Base	*ARObject, BinaryManifestAddressableObject, Identifiable, MultilanguageReferrable, Referrable*			
Aggregated by	CpSoftwareClusterBinaryManifestDescriptor.metaDataField			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
size	PositiveInteger	0..1	attr	The value of this attribute represents the size of the meta-data field in bytes.
value	VerbatimString	0..1	attr	This attribute specifies the value of the meta-data field.

Table 11.28: BinaryManifestMetaDataField

[constr_5204] Existence of attribute BinaryManifestMetaDataField.category

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestMetaDataField, attribute category shall exist.⌋

[constr_5205] Existence of attribute BinaryManifestMetaDataField.size

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestMetaDataField, attribute size shall exist.⌋

[constr_5217] Existence of attribute BinaryManifestMetaDataField.value

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestMetaDataField of category IMMUTABLE_TABLES_-CHECKSUM, attribute value shall exist.⌋

[constr_5206] Existence of attribute BinaryManifestMetaDataField.symbol

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestMetaDataField, attribute symbol shall exist .⌋

[constr_5207] Existence of attribute BinaryManifestMetaDataField.address

Imposition time: IT_BinObjMetaData

⌈For each BinaryManifestMetaDataField, attribute address shall exist.⌋

Please note that the meta-data of a Software Cluster Binary Manifest represent information that is immutable during the phase of connecting Software Clusters with each other.

11.4 Software Cluster Extraction

A System with category SYSTEM_DESCRIPTION is typically used to describe the complete vehicle with all included ECUs. Such a SYSTEM_DESCRIPTION may also contain several CpSoftwareClusters that are assigned to different EcuInstances by CpSoftwareClusterToEcuInstanceMappings.

To describe the content of a single CpSoftwareCluster a new System category is introduced:

[TPS_SYST_02343] System with category SW_CLUSTER_SYSTEM_DESCRIPTION

Upstream requirements: RS_SYST_00060

⌈A System with category SW_CLUSTER_SYSTEM_DESCRIPTION describes the content of a single CpSoftwareCluster.⌋

[TPS_SYST_02344] SW_CLUSTER_SYSTEM_DESCRIPTION content

Upstream requirements: RS_SYST_00060

⌈A System with category SW_CLUSTER_SYSTEM_DESCRIPTION shall only contain the CpSoftwareCluster relevant content, e.g.

- the EcuInstance to which the CpSoftwareCluster is mapped by CpSoftwareClusterToEcuInstanceMapping,

- the ApplicationPartitions to which the CpSoftwareCluster is mapped by CpSoftwareClusterResourceToApplicationPartitionMapping,
- the CompositionSwComponentTypes referenced by the CpSoftwareCluster in the role swComposition with all included SwComponentPrototypes and all elements used by these SwComponentPrototypes directly or indirectly,
- the SwComponentPrototypes referenced by the CpSoftwareCluster via SwComponentPrototypeAssignment and all elements used by these SwComponentPrototypes directly or indirectly,
- the CpSoftwareClusterToResourceMappings that references the CpSoftwareCluster in the role provider or requester with all CpSoftwareClusterServiceResources that in turn are referenced by the CpSoftwareClusterToResourceMappings,
- the SwConnectors that describe the communication relation between SwComponentPrototypes of the CpSoftwareCluster in focus,
- the PortInterfaceMappings that are referenced by the included SwConnectors and do not lead to a conversion of the data/operation representation since the data scaling between CpSoftwareClusters is excluded,
- the DataMappings that describe the communication relation to different CpSoftwareClusters and to SwComponentPrototypes outside of the CpSoftwareCluster in focus,
- the communication matrix description related content that is related to the included SystemSignals, e.g. ISignals, ISignalTriggerings, ISignalIPdus and all the rest of them.

⌋

Please note that in some cases the relevant DataMappings for the CpSoftwareCluster may be described in the SYSTEM_DESCRIPTION on the opposite side, i.e. on different CpSoftwareClusters or on SwComponentPrototypes outside of the CpSoftwareCluster. The reason is that in the SYSTEM_DESCRIPTION the definition of DataMappings is sufficient on one side. But since these side will be removed during the creation of the SW_CLUSTER_SYSTEM_DESCRIPTION the relevant DataMappings shall be shifted to the CpSoftwareCluster in focus.

For the Ecu and RTE Configuration a System with category ECU_EXTRACT is derived from the SYSTEM_DESCRIPTION, ECU_SYSTEM_DESCRIPTION or SW_CLUSTER_SYSTEM_DESCRIPTION as described by [TPS_SYST_01139].

The derivation of an ECU_EXTRACT is a model transformation since a “flat view” of SwComponentPrototypes running on the EcuInstance is expected by the RTE.

The SwComponentPrototypes that are included in the CompositionSwComponentType that is referenced by a CpSoftwareCluster in the role swComposition need to be flattened according to the rules described in chapter 14 in the ECU_EXTRACT. So in case of a SW_CLUSTER_SYSTEM_DESCRIPTION the ECU_EXTRACT represents the "flat view" of a single CpSoftwareCluster.

Please note that during the creation of the ECU_EXTRACT the «instanceRef»s in PortElementToCommunicationResourceMapping shall be adapted because of the process of flattening the hierarchical Software Composition into the "flat view" representation.

[constr_5208] Existence of System.swCluster

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.swCluster shall exist at least once.⌋

[constr_5209] Existence of reference CpSoftwareCluster.swComponentAssignment.swComponent

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.swCluster.swComponentAssignment.swComponent shall exist.⌋

[constr_5210] Existence of reference SystemMapping.portElementToComResourceMapping

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.portElementToComResourceMapping shall exist at least once.⌋

[constr_5211] Existence of reference PortElementToCommunicationResourceMapping.communicationResource

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.portElementToComResourceMapping.communicationResource shall exist at least once.⌋

[constr_5212] Existence of reference SystemMapping.resourceToApplicationPartitionMapping

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.resourceToApplicationPartitionMapping shall exist.⌋

[constr_5213] Existence of reference CpSoftwareClusterResourceToApplicationPartitionMapping.applicationPartition

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.resourceToApplicationPartitionMapping.applicationPartition shall exist.⌋

[constr_5214] Existence of reference CpSoftwareClusterResourceToApplicationPartitionMapping.resource

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.resourceToApplicationPartitionMapping.resource shall exist.⌋

[constr_5215] Existence of reference CpSoftwareClusterToResourceMapping.serviceResource

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, the reference System.mapping.softwareClusterToResourceMapping.serviceResource shall exist.⌋

[constr_5216] Existence of reference CpSoftwareClusterToResourceMapping.requester and/or provider

Imposition time: IT_SwCluSysDesc

⌈In a System with category SW_CLUSTER_SYSTEM_DESCRIPTION, at least one of the references System.mapping.softwareClusterToResourceMapping.requester or System.mapping.softwareClusterToResourceMapping.provider shall exist.⌋

11.4.1 Software Cluster Extraction and DataMappings

The creation of the SW_CLUSTER_SYSTEM_DESCRIPTION for the HOST_SOFTWARE_CLUSTER takes a special role. The DataMappings and CpSoftwareClusterToResourceMappings of all CpSoftwareClusters that are mapped to the same EcuInstance as the HOST_SOFTWARE_CLUSTER shall be made available in the SW_CLUSTER_SYSTEM_DESCRIPTION of the HOST_SOFTWARE_CLUSTER.

This is shown in the example in Figure 11.12, where the Mappings of the outerPort that is connected to “Composition1” are available in the SW_CLUSTER_SYSTEM_DESCRIPTION for “SWCL11” where the “Composition1” is located and the “HOST” CpSoftwareCluster.

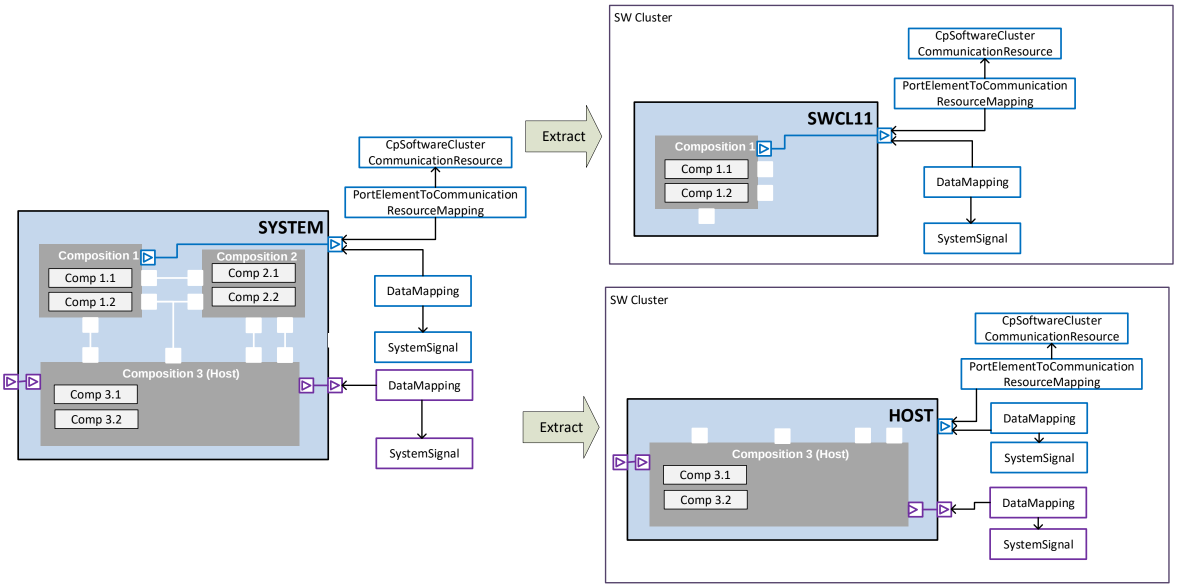

Figure 11.12: Handling of DataMapping during creation of SW_CLUSTER_SYSTEM_DESCRIPTION

The DataMappings on the HOST_SOFTWARE_CLUSTER are necessary for the generation of the AUTOSAR COM Stack. ISignals that are referencing the SystemSignals are mapped into ISignalIPdus and these ISignalIPdus are instantiated on the PhysicalChannels via PduTriggerings. This information is necessary to derive the COM Pdus. The ISignalIPdus are then mapped into Frames for communication over CAN or FlexRay or are assigned to ProvidedServiceInstances or ConsumedServiceInstances for communication over SOME/IP. All information that is necessary to configure the COM Stack shall be available in the HOST_SOFTWARE_CLUSTER.

The outerPorts of the APPLICATION_SOFTWARE_CLUSTERs and the available DataMappings and CpSoftwareClusterToResourceMappings in these CpSoftwareClusters are used to configure the RTE and the Transformers.

12 Usage of the System Template

As introduced in [TPS_SYST_01003] the System Template is used to describe a System with category SYSTEM_CONSTRAINT_DESCRIPTION, a System with category ABSTRACT_SYSTEM_DESCRIPTION and a System with category SYSTEM_DESCRIPTION. System with category SYSTEM_EXTRACT is described in more detail in chapter 13. System with category ECU_EXTRACT is described in more detail in chapter 14.

Certain elements of the System Template may have a different meaning at the different stages of the AUTOSAR Methodology. The following sections describe the differences.

12.1 System Constraint Description

Meta-classes, Chapters	Usage to describe the System Constraints	Usage to describe the System Configuration
CommunicationCluster, EcuInstance (Chapter 3)	The Topology is completely described in the System Constraint Description.	The Topology description will be unchanged copied to the System Configuration description. The Topology may only be changed during another iteration development step of the whole system.
FrameTriggering, PduTriggering, ISignalTriggering (Chapter 6)	The System with category SYSTEM_CONSTRAINT_DESCRIPTION describes all FrameTriggerings that are predefined on all CommunicationClusters of a vehicle. The predefinition of the communication matrix forces the system generator to use the given FrameTriggerings. Constraints for the system generator arise here e.g. from the used bus bandwidth, used identifiers as well as from the timing and at which position in a Frame a Pdu is transmitted on a PhysicalChannel on a CommunicationCluster. Such a manual definition of the communication can be made for any reason where it is necessary to restrict the system generator. One example is the usage of legacy EcuInstances in an AUTOSAR System. The FrameTriggerings that are transmitted or received by these legacy EcuInstances are constraints for the system generator because they cannot be changed, if the compatibility is supposed to be achieved without any changes at the legacy EcuInstances.	In contrary to the System with category SYSTEM_CONSTRAINT_DESCRIPTION the final System with category SYSTEM_DESCRIPTION contains all FrameTriggerings, PduTriggerings, ISignalTriggerings that will be sent by any EcuInstance in the car. No matter if they were predefined (system constraint) or if they were generated by the system generator. The available information, in addition to the information, which is inserted by the AUTOSAR Ecu configuration generator step, will be used as input to configure the Basic SW for the communication.
Gateway (Chapter 8)	The System with category SYSTEM_CONSTRAINT_DESCRIPTION describes all Gateways in the system including their IPduMappings and ISignalMappings that are predefined. The reasons for such predefinitions are quite the same as for the predefinitions of the FrameTriggerings.	In contrary to the System with category SYSTEM_CONSTRAINT_DESCRIPTION the final System with category SYSTEM_DESCRIPTION describes all Gateways with all their IPduMappings and ISignalMappings. No matter if they were predefined (System Constraint) or if they were generated by the System Generator.
SwcToEcuMapping (Section 5.1.1)	The mapping of Software Components to EcuInstances may be predefined. The predefinition will force the system generator to use the specified mapping. Thus, with the SwcToEcuMapping element it is possible to describe that one or more Software Components shall be mapped to a specific EcuInstance.	In a complete System with category SYSTEM_DESCRIPTION, all Software Components are mapped to EcuInstances.
MappingConstraint (Section 5.1.4) ComponentClustering (Section 5.1.4.1) ComponentSeparation (Section 5.1.4.2)	There may be system constraints that limit the system generators freedom to map Software Components to arbitrary EcuInstances. These system constraints can be necessary e.g. for optimization and safety reasons to make additional guidelines for the System Generator.	After the mapping has been completed, the System with category SYSTEM_DESCRIPTION will contain mapping descriptions for all elements, and the mapping constraints are obsolete. But that does not mean that mapping constraints have to be deleted after the system generation step. By deleting the mapping constraints you would lose the information why a mapping of a Software Component to an EcuInstance is chosen.

▽

△

Meta-classes, Chapters	Usage to describe the System Constraints	Usage to describe the System Configuration
DataMapping (Section 5.2) SenderReceiverToSignalMapping (Section 5.2.1.1) SenderReceiverToSignalGroupMapping (Section 5.2.1.2) ClientServerToSignalMapping (Section 5.2.1.3)	The System with category SYSTEM_CONSTRAINT_DESCRIPTION may describe the predefined mapping of Software Components to certain EcuInstances (see chapter 5.1.1). Only if such a mapping exists, it is reasonable to define the DataMapping of the data exchanged between the Software Components.	In contrary to the System with category SYSTEM_CONSTRAINT_DESCRIPTION the final System with category SYSTEM_DESCRIPTION shall contain all DataMapping definitions. No matter if they were predefined (system constraint) or if they were generated by the System-Generator.
SignalPathConstraint (Section 5.2.2) CommonSignalPath (Section 5.2.2.1) ForbiddenSignalPath (Section 5.2.2.2) PermissibleSignalPath (Section 5.2.2.3) SeparateSignalPath (Section 5.2.2.4)	It can be necessary e.g. for optimization and safety reasons to make additional guidelines for the System Generator, which specific way a VariableDataPrototype or ClientServerOperation should take in the network without defining in which Pdu and Frame it is transmitted.	SignalPathConstraints are not an obligatory part of the System with category SYSTEM_DESCRIPTION. In the final System with category SYSTEM_DESCRIPTION every ISignal is assigned to a Pdu and every Pdu is assigned to a Frame. Thereby the paths of VariableDataPrototypes or ClientServerOperations on the network are implicitly described. But that does not mean that the SignalPathConstraints have to be deleted after the system generation step. By deleting the SignalPathConstraints you would lose the information why you have chosen e.g. a specific mapping of an ISignal into a Pdu. If you extend or change the system at a later stage the missing SignalPathConstraints could lead to not wanted signal mappings by the System Generator.

Table 12.1: Usage of the System Template

12.2 Abstract System Description

[TPS_SYST_01134] Abstract System Description ⌈Due to the fact that the functional view on vehicle system can differ from the actual technical definition of the software-architectures of individual EcuInstances the System Template optionally allows to define a System with category ABSTRACT_SYSTEM_DESCRIPTION.⌋

[TPS_SYST_01135] Refactoring of an Abstract System Description into a project specific technical view of the software architecture ⌈The System with category ABSTRACT_SYSTEM_DESCRIPTION concentrates on the functional aspects of the system design and provides an own abstract VFB. During the further activities this abstract view shall be refactored into a more project specific technical view of the software architecture.

It is important to note that during the refactoring of the System with category ABSTRACT_SYSTEM_DESCRIPTION into the System with category SYSTEM_DESCRIPTION no restrictions to the allowed actions apply (This is in contrast to the activity of deriving the System with category SYSTEM_EXTRACT from the System with category SYSTEM_DESCRIPTION, see [TPS_SYST_01123].⌋

[TPS_SYST_01136] ViewMapSet and ViewMap are used to trace the transformations between different models ⌈The ViewMapSet and ViewMap elements are used to trace the transformations between different models within the AUTOSAR environment.⌋

These classes are described in more detail in the Generic Structure Template [1].

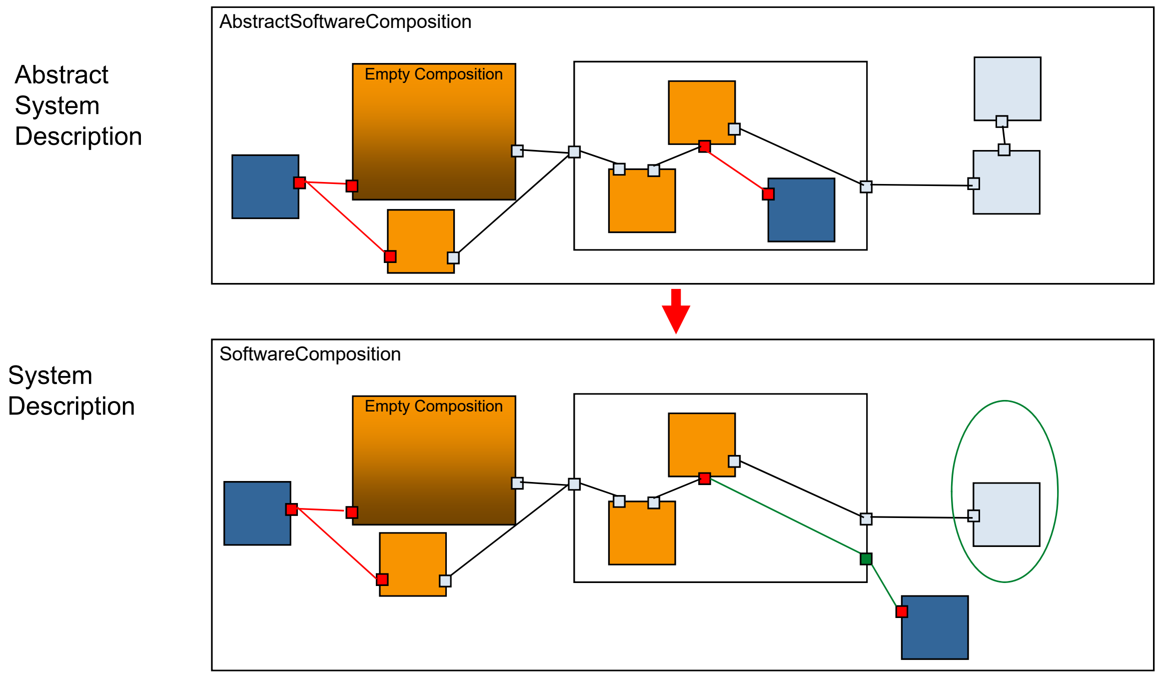

Figure 12.1: Abstract System Description refactoring to a System Description

13 System Extract of the System Configuration Description

This chapter describes contents and creation of the AUTOSAR work product System with category SYSTEM_EXTRACT, based on Meta Model elements contained in the System Template and Software Component Template.

The System with category SYSTEM_EXTRACT is introduced to allow a collaboration between an OEM and a Supplier.[1] The OEM/Supplier Collaboration scenario is described in more detail in chapter 13.1.

The OEM is often only interested in the required functionality and the integration of the functionality into the System. Thus the OEM provides a basis for designing a subsystem, which is developed by the supplier. One difference to the System with category ECU_EXTRACT is that the System with category SYSTEM_EXTRACT is not fully decomposed and still needs to be refined before it forms the basis for the ECU configuration. Another difference is that a System with category SYSTEM_EXTRACT is not fixed to an EcuInstance.

[TPS_SYST_01123] System Extract may cover one or many EcuInstances ⌈The System with category SYSTEM_EXTRACT may cover one or many EcuInstances.⌋

The System with category SYSTEM_EXTRACT is using the same meta model elements as the System with category SYSTEM_DESCRIPTION. The System with category SYSTEM_DESCRIPTION is a special case of a System with category SYSTEM_EXTRACT. From the technical point of view there is no difference. The distinction is only made for the sake of Methodology [3].

In the System with category SYSTEM_EXTRACT the OEM strips all information from the System with category SYSTEM_DESCRIPTION that is not needed for the definition of the subsystem. There is one exception to this simple "remove" rule: the communication mapping may need to be extended, which will be described in more detail in chapter 13.2.

[TPS_SYST_03000] Co-existing System with category SYSTEM_DESCRIPTION and System with category SYSTEM_EXTRACT

Upstream requirements: RS_SYST_00045

⌈In order to be able to handle one System with category SYSTEM_DESCRIPTION and one or several Systems with category SYSTEM_EXTRACT within the same workspace it shall be possible to provide different full qualified names to the elements of System with category SYSTEM_EXTRACT.⌋

[1] Collaboration scenarios between different departments of an OEM are also supported by the System with category SYSTEM_EXTRACT. For the sake of simplicity such scenarios are not addressed here.

When different Systems with various categories co-exist it is possible to define ViewMap and ViewMapSet between their elements according to [TPS_SYST_01136].

In contrast to the System with category ECU_EXTRACT the System with category SYSTEM_EXTRACT may contain CompositionSwComponentTypes. Empty CompositionSwComponentTypes in the System with category SYSTEM_EXTRACT represent subsystems that need to be refined by a Supplier. Figure 13.1 shows an example where a System with category SYSTEM_DESCRIPTION is stripped down to a subsystem.

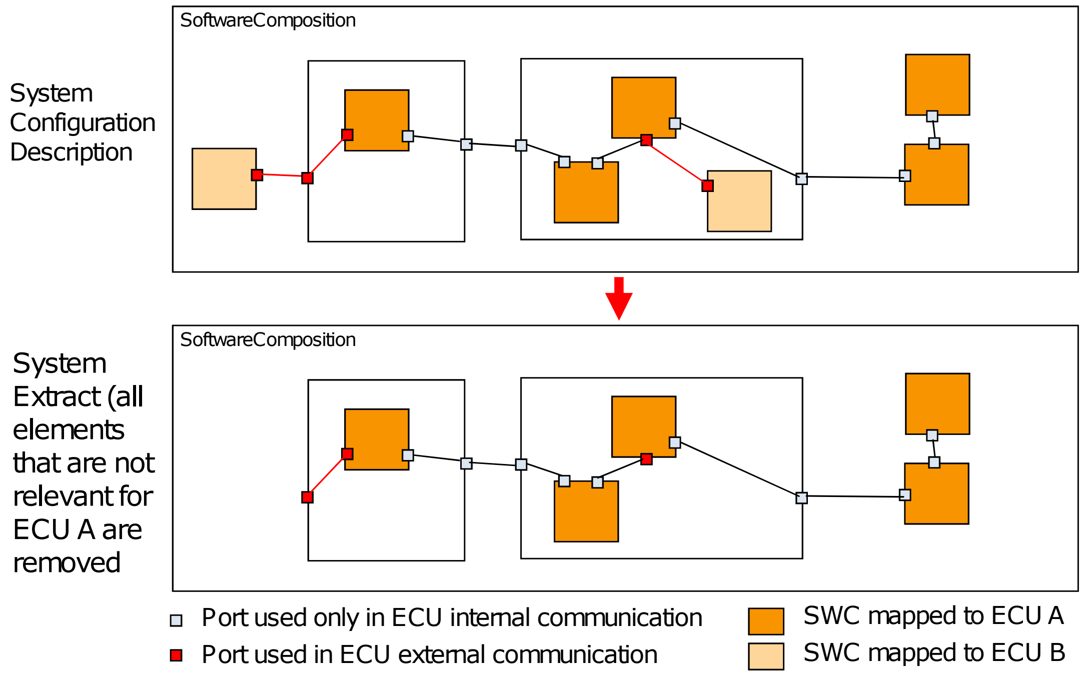

Figure 13.1: System Extract creation: irrelevant elements are removed from the System Description

13.1 OEM/Supplier Collaboration Scenario

In an important collaboration scenario, an OEM commissions a supplier to provide implementations of one or more functionalities to be integrated into an AUTOSAR system in the form of Application Components. The OEM is primarily interested in the required functionality and the interfaces defining the integration of the Software Component into the System VFB rather than the internal structure of such a component. On the other hand, the supplier, delivering both the component implementation in combination with the ECU it is destined to run on, may claim the internal structure of such a higher-level component contains substantial intellectual property, and hence may not want to disclose its internal works to the OEM.

Effectively, the use case can be described in the following manner:

- The OEM generates a System with category SYSTEM_EXTRACT from the System with category SYSTEM_DESCRIPTION. From the System with category SYSTEM_DESCRIPTION all elements are removed that are not relevant for the design of the subsystem, such as SW components or topology elements.
- The OEM can deliver a sub-structure of Software Compositions or even Atomic Software Components in the System with category SYSTEM_EXTRACT. But the System with category SYSTEM_EXTRACT can also contain empty Software Compositions. The OEM shall have the possibility to define only the outer shell of a Software Composition that is to implement a certain functionality. Such an empty CompositionSwComponentType does contain all the provided and required ports with the included ReceiverComSpecs and SenderComSpecs describing the requested component's outside communication needs. But it does not need to contain SwComponentPrototypes or SwConnectors at this stage.
- Such empty components are added to a System's VFB, the outside ports are connected with other components in the VFB. However, at this stage the inner structure of such CompositionSwComponentType can still be left empty.
- The System with category SYSTEM_EXTRACT contains the mapping of components to the target EcuInstances, including the empty compositions. Signal mappings affecting the empty compositions are targeting the CompositionSwComponentType's ports.
- The OEM delivers the System with category SYSTEM_EXTRACT to the Supplier.
- The Supplier adds the substructure to the empty CompositionSwComponentTypes by adding SwComponentPrototypes and SwConnectors. This once more leads to a hierarchical VFB, effectively the Supplier creates a local System Description for his subsystem.
- The Supplier adjusts the Signal mappings to the actual ports of the inner AtomicSwComponentType prototype.
- The Supplier generates the System with category ECU_EXTRACT from his ECU-local system description. The resulting System with category ECU_EXTRACT does not include prototypes of type CompositionSwComponentType any longer.
- Based on this System with category ECU_EXTRACT the actual ECU configuration is done.

When the supplier receives the System with category SYSTEM_EXTRACT from the OEM he has basically two choices how to proceed:

1. The Supplier takes the System with category SYSTEM_EXTRACT of the OEM as the structural basis for the ECU development. In this case the following steps may follow:

  - The Supplier adds the substructure to the empty CompositionSwComponentTypes by adding SwComponentPrototypes and SwConnectors. This once more leads to a hierarchical VFB, effectively the Supplier creates a local System Description for his subsystem (System with category ECU_SYSTEM_DESCRIPTION).
  - The Supplier adjusts the Signal mappings to the actual ports of the inner AtomicSwComponentType prototype.

2. The Supplier creates an own structure to base the ECU development on System with category ECU_SYSTEM_DESCRIPTION and perform a view mapping between the OEM's System with category SYSTEM_EXTRACT and the System with category ECU_SYSTEM_DESCRIPTION. In this case the following steps may follow:
  - The Supplier develops an own structure how the ECU shall be designed but needs to respect the required outer boundary of the OEM's required communication behavior (ReceiverComSpecs and SenderComSpecs).
  - The Supplier adjusts the Signal mappings to the actual ports of the inner AtomicSwComponentType prototype.

When the design of the System with category ECU_SYSTEM_DESCRIPTION is complete the following steps follow:

- The Supplier generates the System with category ECU_EXTRACT from his System with category ECU_SYSTEM_DESCRIPTION. The resulting System with category ECU_EXTRACT does not include prototypes of type CompositionSwComponentType any longer.
- Based on this System with category ECU_EXTRACT the actual ECU configuration is done.

13.2 Data Mapping in the System Extract

As mentioned before, there is a slight complication to the simple "remove" rule. This can be shown best with an example.

Example: Assume a simple topology with two EcuInstances A and B and three Pdus X (sent from A to B), Y (sent from B to A) and Z (sent from B to A) as shown in Figure 13.2.

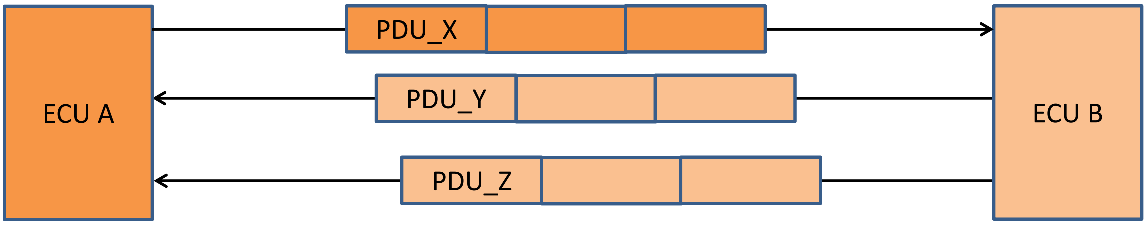

Figure 13.2: Example topology with two EcuInstances and three Pdus exchanged between them

Furthermore assume a composition of software-components realized by the meta-class CompositionSwComponentType as shown in Figure 13.3. It consists of six SwComponentPrototypes 'A1' to 'A3' (aggregated in composition 'SwCompA'), 'B1' / 'B2' (aggregated in composition 'SWCompB'), 'C1' (aggregated in composition 'SWCompAplusBplusC') and an empty composition 'SWCompC'.

The overall composition 'SWCompAplusBplusC' aggregates 'SwCompA', 'SWCompB', the empty 'SWCompC' and the SwComponentPrototype 'C1'.

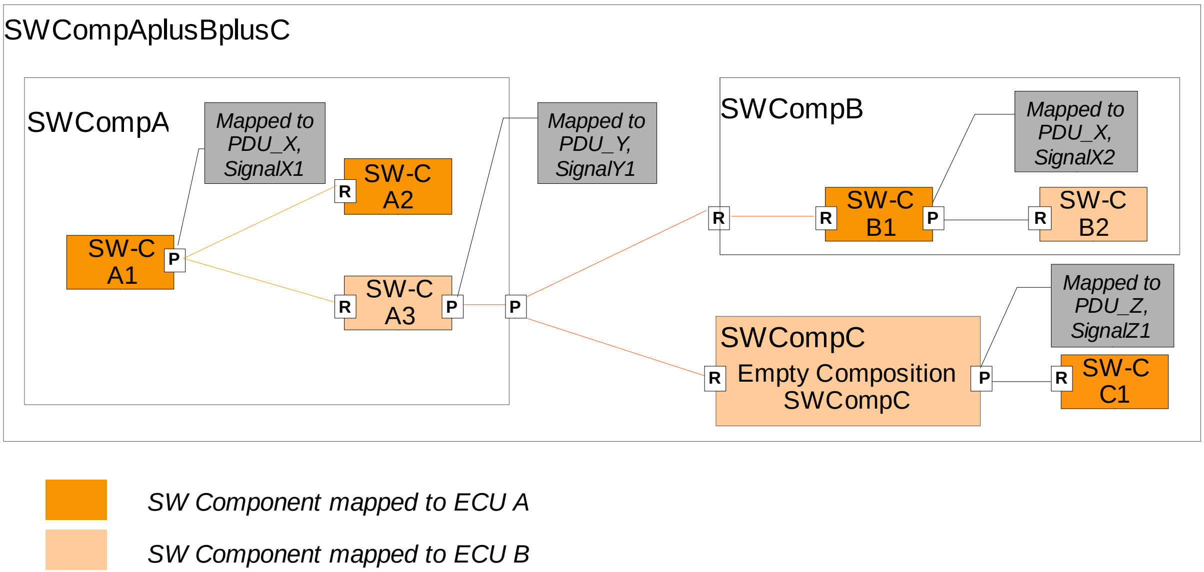

Figure 13.3: Example SW composition with mapping information

The atomic SwComponentPrototypes 'A1', 'A2', 'B1' and 'C1' are mapped to 'ECU A'. The atomic SwComponentPrototypes 'A3', 'B2' and the empty composition 'SWCompC' are mapped to 'ECU B'. The data sent from

- 'A1' to 'A3' is mapped to 'PDU_X', 'SignalX1',
- 'B1' to 'B2' is mapped to 'PDU_X', 'SignalX2' and
- 'A3' to 'B1' and 'A3' to 'SWCompC' is mapped to 'PDU_Y', 'SignalY1'
- 'SWCompC' to 'C1' is mapped to 'PDU_Z', 'SignalZ1'

As usual, the data mapping rules refer to the VariableDataPrototype in the PPortPrototype of the sending SW component. Note that DataMappings can be performed on compositions and on atomic SwComponentPrototypes as described in chapter 5.2.1. [2]

Figure 13.4 shows how the System extract for ECU A and for ECU B of this SW composition would look like: Only those elements are included that are relevant for the subsystem.

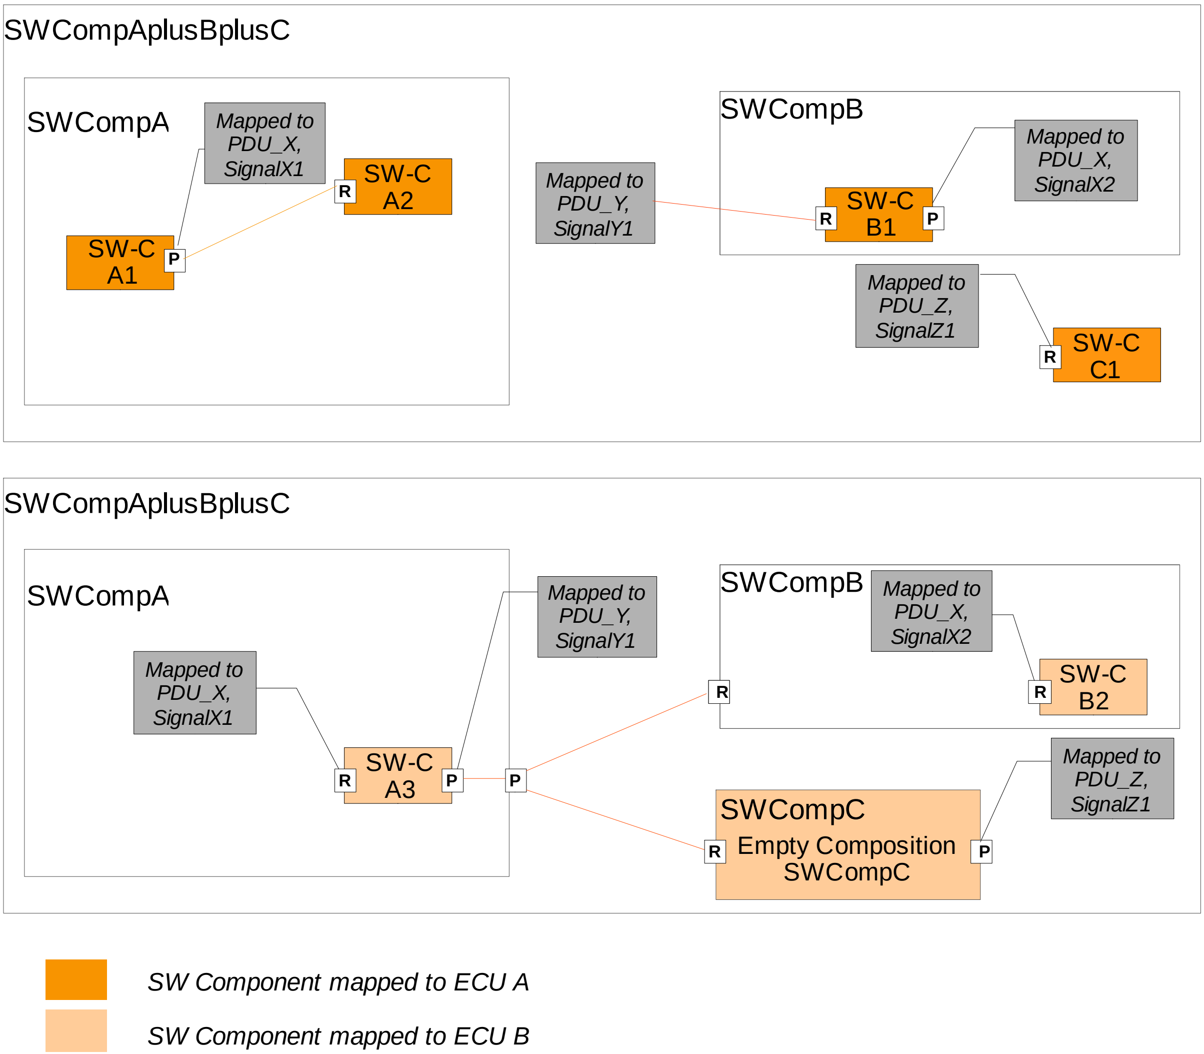

Figure 13.4: Example System extract for ECU A (upper figure) and ECU B (lower figure) of above introduced composition

In both figures all SwComponentPrototypes and compositions that are mapped onto the EcuInstance are included. The SwConnector between these SwComponentPrototypes are also included. Furthermore, the relevant topology information and communication matrix have to be included, but they are out of scope of this example.

SwConnectors that were used to connect to SW components that are not included in the System Extract are not included. Instead, the mapping to an ISignal in a Pdu is used to identify the source/destination of that data.

[2]Data mapping is allowed on empty compositions and on compositions that contain atomic SwComponentPrototypes.

The problem that new mapping rules have to be added arises for example in the System Extract for ‘ECU A’ with the mapping to ‘PDU Y’, ‘SignalY1’: Since SW component ‘A3’, which was referenced in the original mapping, is no longer included, the data mapping needs a new data element in a port to reference to. In the example, it is the required port of ‘B1’, so that the Supplier has the information that B1 receives the data via ‘PDU Y’.

13.3 SW component inclusion and top level data mapping

In section 13.2 the approach is to provide the DataMapping on the PortPrototypes of the SwComponentPrototypes which are mapped to one EcuInstance. Since the granularity of mapping SwComponentPrototypes to EcuInstances is possible for individual atomic SwComponentPrototypes this approach may result in many DataMappings from different software component PortPrototypes to the same SystemSignal (depending where in the hierarchical structure they are located).

An alternative approach is to provide the complete communication information of the whole System Extract on the RootSwCompositionPrototype and perform the DataMapping on the PortPrototypes of the RootSwCompositionPrototype only. This approach is illustrated in figure 13.5.

PortPrototypes are created on the RootSwCompositionPrototype representing the external communication of this EcuInstance. DelegationSwConnectors are created to establish the communication of the external software components with the software components inside the local EcuInstance.

In figure 13.5 the software components X, Y and Z are mapped to remote EcuInstances. Their communication needs are collected in PortPrototypes on the RootSwCompositionPrototype and the communication is delegated via SwConnectors inside the hierarchical software component structure.

In this example the approach for X and Y is trivial since there are only some DelegationSwConnectors required to connect the PortPrototypes of the RootSwCompositionPrototype with the PortPrototypes of the respective SwComponentPrototypes.

But for SwComponentPrototype Z the approach needs to be extended, because the communication on system level is designed to happen inside the composition V. In this case the communication needs to be delegated out of the composition (creation of DelegationSwConnectors inside the composition V) to be visible in the RootSwCompositionPrototype. Then again the approach of connection to the RootSwCompositionPrototype can be applied.

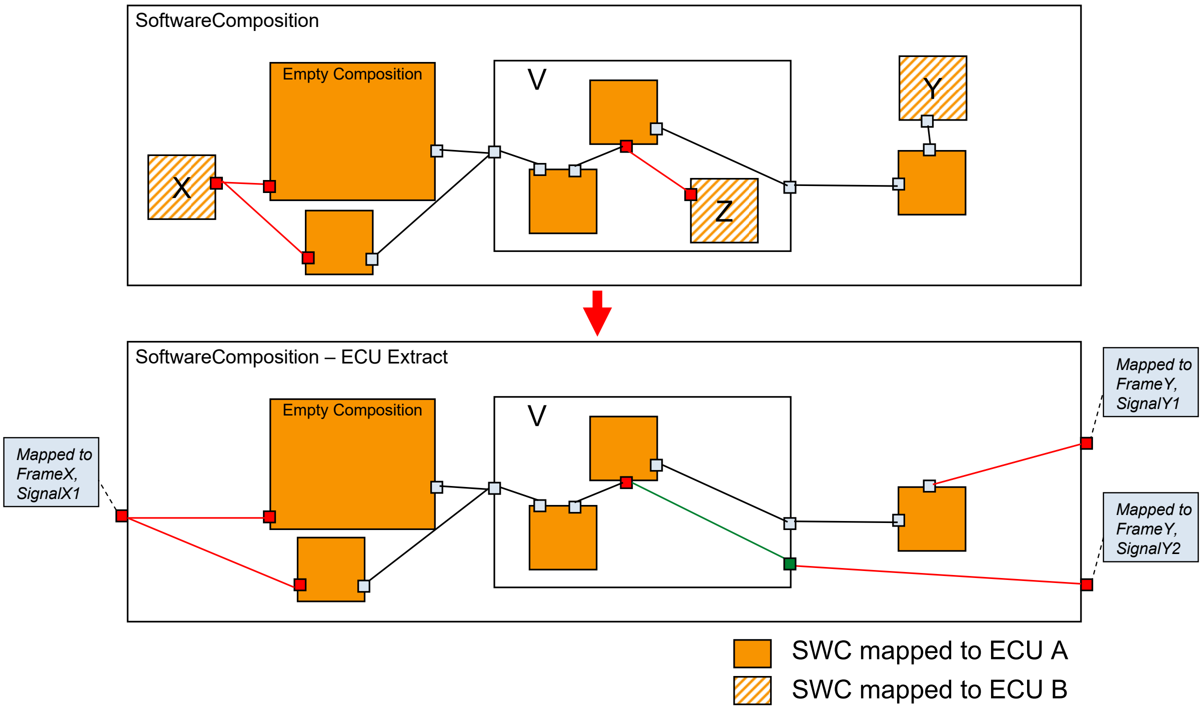

Figure 13.5: Example with software components mapped to two ECUs

13.4 Port-Interface Mapping in the System Extract

A similar problem as the one with DataMappings described in chapter 13.2 and chapter 13.3 exists for the PortInterfaceMappings as well. To illustrate this Figure 13.6 depicts an example with software components mapped to two different ECUs.

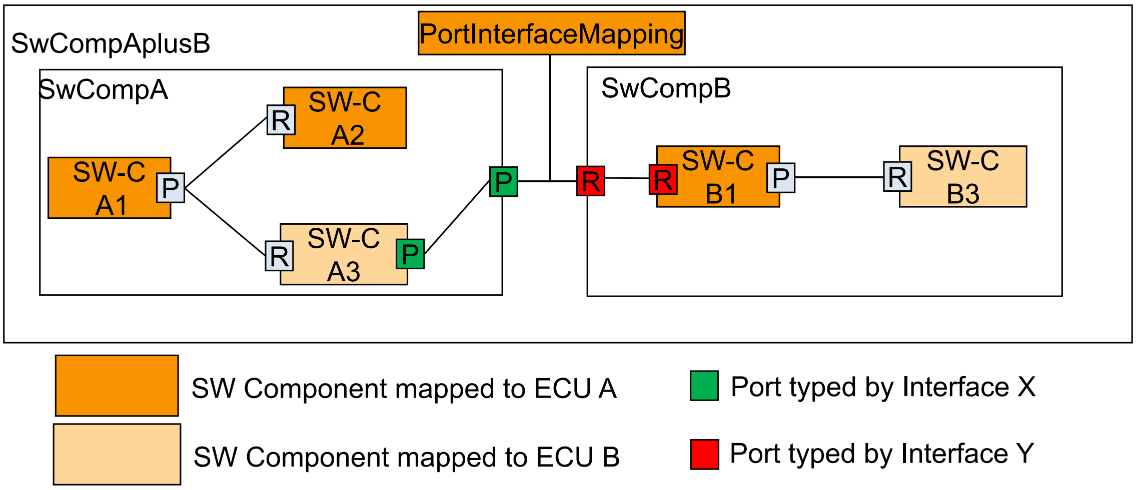

Figure 13.6: Example with software components mapped to two ECUs

Hereby the PPortPrototype typed with PortInterface *X* of *SWCompA* is connected with the RPortPrototype typed with PortInterface *Y* of *SWCompB* by means of an AssemblySwConnector. This AssemblySwConnector has an attached PortInterfaceMapping to perform a mapping between the elements (see chapter 4.3.1.5 of [4]) of the two otherwise incompatible PortInterfaces *X* and *Y*.

A System Extract for ECU *A* is now created by applying the approach described in chapter 13.3, i.e., by providing the complete communication information of the whole System Extract on the RootSwCompositionPrototype and performing the DataMapping on the PortPrototypes of the RootSwCompositionPrototype only.

When doing this however the following two additional things have to be considered:

- The PortInterfaceMapping shall be preserved during this process
- The information about the PortInterfaces referenced by the PortPrototypes connected by the AssemblySwConnector referencing the PortInterfaceMapping shall be preserved during this process

Just as in the approach described in chapter 13.3 PortPrototypes are created on the RootSwCompositionPrototype representing the external communication of this EcuInstance. The RPortPrototypes however are not typed by the PortInterface *X* of the RPortPrototypes of the SwComponentPrototypes inside *ECU A* (*SWCompB* in the example) but by the PortInterface *Y* of the PPortPrototype which was connected to the RPortPrototypes by means of the AssemblySwConnector. Afterwards the just like in the approach described in chapter 13.3

DelegationSwConnectors are created to connect the PortPrototypes of the RootSwCompositionPrototype with the corresponding RPortPrototypes of the SwComponentPrototypes inside *ECU A*.

This however yields a DelegationSwConnector between RPortPrototype typed by PortInterface *Y* (which has been created on the RootSwCompositionPrototype) and the RPortPrototype typed by PortInterface *X* of *SWCompB*. In order to perform a mapping between the elements of these otherwise incompatible interfaces, the PortInterfaceMapping which has initially been referred to by the AssemblySwConnector needs to be referenced by the DelegationSwConnector.

The final result of this process in depicted in Figure 13.7

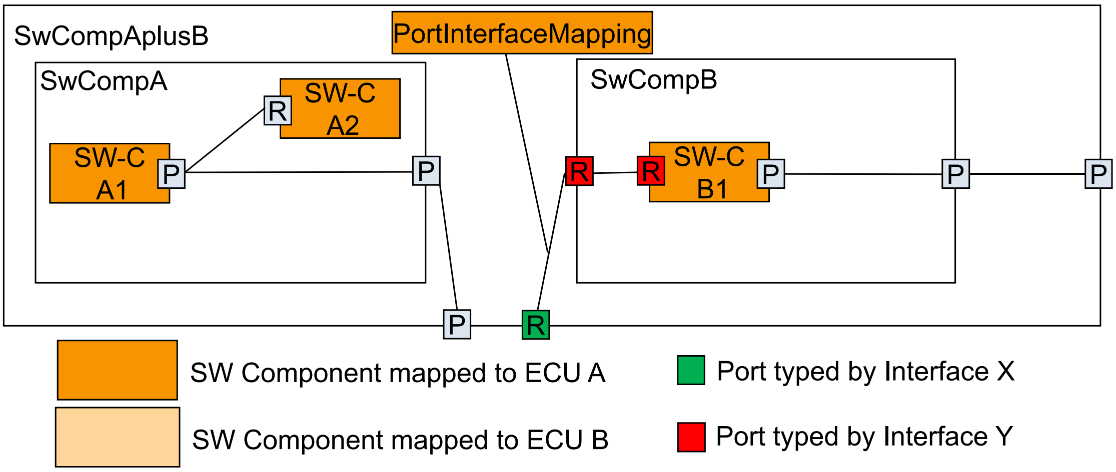

Figure 13.7: Example with software components mapped to two ECUs

14 ECU Extract of the System Configuration Description

This chapter describes contents and creation of the AUTOSAR System with category ECU_EXTRACT, based on Meta Model elements contained in the System Template and Software Component Template.

The System with category ECU_EXTRACT represents the view of one specific EcuInstance onto the overall System with category SYSTEM_DESCRIPTION. The System with category ECU_EXTRACT forms the basis for configuring that particular EcuInstance in focus.

For instance, RTE configuration fundamentally depends on the number and types of SwComponentPrototypes deployed onto the EcuInstance; Services are configured according to those Software Components' ServiceNeeds; the COM-stack BSW modules will be configured considering the EcuInstance's participation in the overall System Network Topology and Communication.

[TPS_SYST_01139] Ecu Extract derived from System Description or System Extract covers exactly one EcuInstance ⌈The System with category ECU_EXTRACT shall only contain the subset of information derived from the System with category SYSTEM_DESCRIPTION or System with category SYSTEM_EXTRACT relevant for configuring the targeted EcuInstance.⌋

In order to keep ECU configuration focused and manageable despite the complexity of a full System Configuration, all other information shall be stripped from the System with category SYSTEM_DESCRIPTION or from the System with category SYSTEM_EXTRACT when creating the System with category ECU_EXTRACT.

AUTOSAR VFB Descriptions naturally form hierarchies of CompositionSwComponentTypes. Consequently, in the System Configuration the SWC-related information for different EcuInstances is not separated but in general is intermingled. In contrast, for the task of ECU configuration (RTE configuration, Service Configuration, Measurement and Calibration) a hierarchically “flat view” on the SwComponentPrototypes running on the EcuInstances is preferable over a hierarchical view, which is more favored by application-software development. Thus, deriving an System with category ECU_EXTRACT actually is a model transformation, following a set of rules described in the following sections.

[constr_9333] FibexElements in ECU_EXTRACT

Imposition time: IT_EcuExt

⌈Each FibexElement that is used in the ECU_EXTRACT shall be referenced by the System element in the role fibexElement.⌋

[TPS_SYST_02313] Ecu Extract derived from ECU_SYSTEM_DESCRIPTION covers an EcuInstance ⌈The System with category ECU_SYSTEM_DESCRIPTION defines the content of a single EcuInstance and the same is true for the derived ECU_EXTRACT. The derived ECU_EXTRACT is flattened and does not contain any hierarchies of CompositionSwComponentTypes.⌋

[TPS_SYST_02314] Ecu Extract derived from SW_CLUSTER_SYSTEM_DESCRIPTION covers a subset of an EcuInstance ⌈The System with category SW_CLUSTER_SYSTEM_DESCRIPTION defines the content of a single CpSoftwareCluster and the same is true for the derived ECU_EXTRACT. The derived ECU_EXTRACT is flattened and does not contain any hierarchies of CompositionSwComponentTypes.⌋

As System- and ECU development typically happens in iterations, the use case of repeatedly extracting the information from an incrementally changing System Configuration needs to be considered. In particular, it shall be possible to detect changes between consecutively generated ECU extracts in order to selectively update the existing ECU configuration (14.6).

AUTOSAR supports the definition and consequently the handling of Variability in the System Configuration. According to the specified binding time associated with a particular VariationPoint, typically some of these variants will already be resolved at the time of a System with category ECU_EXTRACT. If however the binding time occurs in a later stage of the AUTOSAR methodology, i.e. during ECU Configuration or later, the variability needs to be carried over to the System with category ECU_EXTRACT. This also holds true for Variation points that ultimately are resolved at system configuration time but affect post-build configuration parameters. (14.7)

The System with category ECU_EXTRACT logically forms one entity. Therefore, for ease of readability the rest of the chapter assumes just one file, “the XML file”. However, it explicitly is allowed to split the System with category ECU_EXTRACT over several files.

14.1 Topology

Only those Topology elements relevant for the EcuInstance in scope are taken over from the System with category SYSTEM_DESCRIPTION into the System with category ECU_EXTRACT.

- The System with category ECU_EXTRACT is always associated with exactly one EcuInstance. Therefore exactly one EcuInstance is included along with all classes included in EcuInstance by composition: CommunicationControllers and CommunicationConnectors with all their CommConnectorPorts.

- A CommunicationCluster is included along with all its PhysicalChannels if at least one PhysicalChannel is used by the EcuInstance. In other words, if at least one of the included CommunicationConnectors is referenced by any of a CommunicationCluster's PhysicalChannels, the whole CommunicationCluster and all its PhysicalChannels are included.
- From the used PhysicalChannels, only those FrameTriggerings, PduTriggerings, ISignalTriggerings shall be included that are used by the EcuInstance, e.g. they are associated with a FramePort, IPduPort, ISignalPort belonging to one of the EcuInstance's CommunicationConnectors. *Note:* Including just a subset of a PhysicalChannel's FrameTriggerings, PduTriggerings, ISignalTriggerings is possible without changing the PhysicalChannel itself because of the ≪splitable≫ stereotype applied on the PhysicalChannel / FrameTriggering, PduTriggering, ISignalTriggering composition.

As the Topology elements are not modified when taken over into the System with category ECU_EXTRACT, their package structure and short names are not touched (see section 14.5.1).

14.2 Top-level Software Composition

In the System with category SYSTEM_DESCRIPTION the application software composition is hierarchic by nature as described in chapter 4. When mapping SwComponentPrototypes onto concrete EcuInstances using the SwcToEcuMapping class (section 5.1.1), either SwComponentPrototypes of type AtomicSwComponentType, or SwComponentPrototypes of type CompositionSwComponentType are deployed onto one specified EcuInstance.

In order to obtain this ECU-centric view, the hierarchical structure of the System with category SYSTEM_DESCRIPTION needs to be transformed into a 1-layer representation, where one distinguished CompositionSwComponentType hosts all SwComponentPrototypes of type AtomicSwComponentType to run on the EcuInstance. In the System with category ECU_EXTRACT the resulting RootSwCompositionPrototype is a flat structure where the included SwComponentPrototypes become real SWC instances, reflecting the actual resource needs on the targeted EcuInstance.

[TPS_SYST_01140] Ecu Extract contains only SwComponentPrototypes of type AtomicSwComponentType in the RootSwCompositionPrototype ⌈The System with category ECU_EXTRACT only contains SwComponentPrototypes of type AtomicSwComponentType in the RootSwCompositionPrototype which are effectively mapped onto the EcuInstance in focus.⌋

The transformation from hierarchical to flat Software Component structure includes a number of steps, to be performed per ECU. The list below outlining this process assumes that the extraction is done for the first time; if an System with category ECU_EXTRACT already exists from a previous development cycle, the extract shall merely be updated instead of created; for more details on iterative development see section 14.6.

- Create the one CompositionSwComponentType which will represent the ECU's SW subsystem (in further steps referred to as ECU flat view)
- To this ECU flat view, add a SwComponentPrototype for each instance of any AtomicSwComponentType mapped onto the EcuInstance. Copy all the identifiable information from the originating SwComponentPrototype, but assign an unique short name to the new element. The newly created SwComponentPrototypes are typed by the original AtomicSwComponentType.
- Unroll the connector paths leading to and from the included components:
  - For ECU internal communication, use AssemblySwConnector to connect PortPrototypes.
  - For ECU external communication, add delegated PortPrototypes to the ECU flat view CompositionSwComponentType. The delegated PPortPrototypes are allowed to contain a subset of the data that is defined by the inner PPortPrototype as specified by [TPS_SYST_02384]. The delegated RPortPrototypes are allowed to contain a superset of the data that is defined by the inner RPortPrototypes as specified by [TPS_SYST_02385]. Each delegated PortPrototype shall be connected via a DelegationSwConnector with PortPrototypes of the included SwComponentPrototypes that are used for the external communication.
  - VariableDataPrototypes and ClientServerOperations of the delegated PortPrototypes are mapped to SystemSignals.
- If the System with category SYSTEM_DESCRIPTION prescribes an Implementation for a SwComponentPrototype by using SwcToImplMapping, a corresponding constraint needs to be created in the System with category ECU_EXTRACT of the targeted EcuInstance. The SwcToImplMapping's component reference needs to be adjusted to the flat representation, while maintaining the original reference to the Implementation.
- Only ComSpecs on the PortPrototypes of atomic software components are relevant for the RTE generator (see [TPS_SWCT_01568]). The existence of ComSpecs on composition level can be taken into account for setting the values on the atomic level as the atomic level gets created. On the other hand there is no obligation to respect the ComSpec settings on the composition level for the creation of the atomic level. Finally the approach for the creation of ComSpec values on atomic level depends on OEM preferences.

[TPS_SYST_02384] Sending inner Ports may contain the superset of data provided on the outer delegation Port ⌈The outer PPortPrototype on the CompositionSwComponentType is allowed to contain a subset of the provided data that is defined by the inner PPortPrototype of the included SwComponentPrototype that is connected via a DelegationSwConnector to the outer PPortPrototype.⌋

[TPS_SYST_02385] Receiving outer Ports may contain the superset of data delegated to the inner Ports ⌈The inner RPortPrototype on the SwComponentPrototype that is included in the CompositionSwComponentType is allowed to contain a subset of the received data that is defined by the outer RPortPrototype of the CompositionSwComponentType that is connected via a DelegationSwConnector to the inner RPortPrototype.⌋

Figure 14.1 illustrates the process of flattening the hierarchical Software Composition into an ECU Flat View representation, as outlined in the previous paragraphs. The following sections explain the concrete transformation steps in more detail.

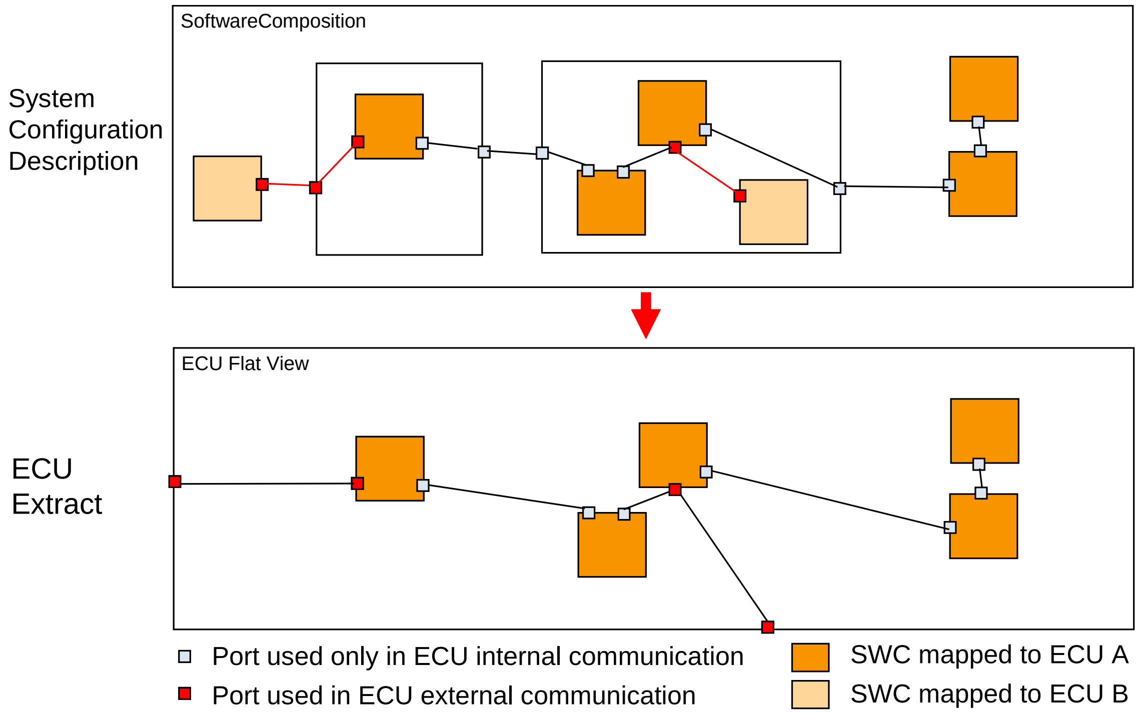

Figure 14.1: Flattening of a hierarchic Software Composition into an ECU Flat View, and the distinction between ports used in internal and those used in external communication.

Please note that instantiation specific scheduling of runnables shall be maintained when generating a System with category ECU_EXTRACT. This maintenance covers the rewrite of the instanceRef to the RTEEvent respectively the aggregation of the instantiationRTEEventProps to the next CompositionSwComponentType.

14.2.1 ECU Flat view

The first step of extracting the ECU specific Software View is the creation of a new CompositionSwComponentType (further referred to as ECU flat view). This new element serves as a container for collecting all SwComponentPrototypes of type AtomicSwComponentType deployed on the EcuInstance. In order to include the ECU flat view into the actual System with category ECU_EXTRACT, the System shall have its child class RootSwCompositionPrototype pointing to this ECU flat view.

Next, all SwcToEcuMappings present in the System with category SYSTEM_DESCRIPTION need to be analyzed according to the precedence rules (Section 5.1.1) in order to establish the exact set of AtomicSwComponentType instances to be included on this EcuInstance.

For each of these component instances, regardless of their order of depth in the System Configuration Description's Component hierarchy, exactly one SwComponentPrototype shall be created in the ECU flat view CompositionSwComponentType. The new element's description and type information shall be taken over from the original SwComponentPrototype as present in the System with category SYSTEM_DESCRIPTION. As an important exception to this rule, the SwComponentPrototype's shortName shall be unique in the name space formed by the ECU flat view.

The ParameterSwComponentTypes are handled in the same way. For ParameterSwComponentTypes there are SwConnectors defined but no communication is involved. For more details see [TPS_SWCT_01422] in the SwComponentTemplate [4]. For ServiceProxySwComponentTypes one small difference applies: This component type can be instantiated at most once per EcuInstance and for a given prototype in the System, instances on several EcuInstances can be created. The replication of ServiceProxySwComponentTypes on several EcuInstances does not require any special treatment of their communication properties.

14.2.2 Internal Communication

When flattening the RootSwCompositionPrototype for the System with category ECU_EXTRACT, not only all of the ECU's Software Components are to be collected in the ECU flat view, but also any connection existing between PortPrototypes of the included SwComponentPrototypes needs to be projected onto the same RootSwCompositionPrototype.

In the hierarchical RootSwCompositionPrototype, communication between Software Components is specified by a combination of AssemblySwConnectors and DelegationSwConnectors. Several DelegationSwConnectors may be combined in case of a multiple-level delegation, however there will always be exactly one AssemblySwConnector on the outermost CompositionSwComponentType the port is delegated to.

In the ECU flat view, any such number of stringed together SwConnectors effectively connecting two PortPrototypes of SwComponentPrototypes mapped to the same EcuInstance are resolved to exactly one AssemblySwConnector per connected port pair. As there are no additional levels of "inner SwComponentPrototypes". DelegationSwConnectors are only used to display the outside communication of an ECU in the ECU flat view.

[constr_3019] In the flat ECU extract each required interface shall be satisfied by connected provided interfaces

Imposition time: IT_EcuExt

⌈In case of the flat System with category ECU_EXTRACT all VariableDataPrototypes specified by the SenderReceiverInterface of the RPortPrototype need to be supplied by some of the PPortPrototypes being connected with SwConnectors.⌋

For the System with category SYSTEM_DESCRIPTION, the Software Component Template Specification [4] allows a CompositionSwComponentType's outer PortPrototype to be connected to more than one inner port, observing a set of compatibility rules between the outer and the inner port's SenderReceiverInterfaces. Such a "merge" and "split" functionality for mixing VariableDataPrototypes is used to limit the number of SwConnectors required to connect PortPrototypes on higher VFB levels and thus reduce complexity in the wiring of such higher-level CompositionSwComponentTypes. On the other hand this means that an AssemblySwConnector in a hierarchical VFB may expand to more than one Port-Port pair. Naturally, in the ECU flat view such "hidden" additional connections need to be made explicit by unrolling them into concrete AssemblySwConnectors.

Additionally PassThroughSwConnector may be used to map PortInterface elements between require and provide outer ports of CompositionSwComponentTypes in order to use RTE features for mapping or conversion instead of real software components. The following paragraph suggests a way how such an unrolling of SwConnectors may be accomplished.

Starting with the top-level RootSwCompositionPrototype indicating the outermost CompositionSwComponentType, the hierarchical software model of SwComponentPrototypes is recursively iterated; for each prototype of CompositionSwComponentType, all its AssemblySwConnectors are being iterated. For each such found AssemblySwConnector both connector ends are evaluated for DelegationSwConnectors further delegating the connection: In order to consider the use cases of signal "merge" and "split", all possible communication partners need to be identified, recursively following DelegationSwConnectors in both directions. For each identified pair of PPortPrototypes and RPortPrototypes *actually exchanging* Information one AssemblySwConnector will be created in the ECU flat view.

In case that a string of SwConnectors started by AssemblySwConnector connects - directly or via DelegationSwConnectors - to a PassThroughSwConnector the

SwConnector string is conjunct with the SwConnector string of the other end of the PassThroughSwConnector. Please note that the “merge” and “split” capability of DelegationSwConnectors and PassThroughSwConnectors requires an individual treatment of the single PortInterface elements for the evaluation of the SwConnector string.

The following rules shall be followed when PortInterfaceMappings are converted for the flat view. PortInterfaceMappings supports the connection of Ports typed by two different PortInterfaces with unequal named PortInterface elements. More details can be found in [4].

- When unrolling a string of SwConnectors into a single SwConnectors all compatibility rules and PortInterfaceMappings of the individual SwConnector need to be considered for determining which VariableDataPrototypes are being transferred between provider and requester. If VariableDataPrototypes are to be filtered out a PortInterfaceMapping shall be provided to the flatten connector such that only the transferred VariableDataPrototypes are included in the mapping.
- When unrolling a string of SwConnectors into a single SwConnector all of the PortInterfaceMappings of the individual SwConnectors need to be considered for combining them into a single PortInterfaceMapping to be associated with a new SwConnector.

14.2.3 External Communication

In a System with category SYSTEM_DESCRIPTION , whenever two SwComponentPrototypes are specified to communicate across EcuInstances, the details of this communication need to be fully specified: VariableDataPrototypes of SenderReceiverInterfaces and ClientServerOperations of ClientServerInterfaces are mapped onto SystemSignals as carriers of information transported across the network. According to 5.2, each instance of a AutosarDataPrototype that is to be sent over AUTOSAR COM shall be mapped exactly once onto its individual SystemSignal, regardless of how many components receive the information or over how many PhysicalChannels the SystemSignal is transported.

As described above, deriving the System with category ECU_EXTRACT from System with category SYSTEM_DESCRIPTION or from System with category SYSTEM_EXTRACT means that all SwComponentPrototypes to be included in the Ecu extract are recreated in an ECU flat view. Consequently, each DataMapping concerning a SwComponentPrototype to be mapped onto the EcuInstance requires that a corresponding DataMapping be created in the System with category ECU_EXTRACT.

The ECU flat view contains delegated PortPrototypes to display the outside communication of an EcuInstance. VariableDataPrototypes and ClientServerOperations of these delegated PortPrototypes are mapped to SystemSignals. The original instance references indicating the mapped AutosarDataPrototype need to be adjusted to the new “flat” location in the ECU flat view.

While for the System with category SYSTEM_DESCRIPTION it is sufficient to describe DataMappings only on the provider side, the System with category ECU_EXTRACT additionally requires such DataMappings on the requiring side’s ports. In this case, a new DataMapping maps to the existing SystemSignal, previously defined in the System with category SYSTEM_DESCRIPTION on the provider side. This is explained in more detail in figure 14.6, that is a continuation of the example from figure 13.3 in chapter 13.2.

To derive an ECU_EXTRACT from a System with category SYSTEM_DESCRIPTION or SYSTEM_EXTRACT unambiguous ClientServerToSignalMappings are required for inter-ECU n:1 client-server communication. In particular the communication path from the server to each client shall be uniquely mapped.

In this context, "communication path" encompasses the set of delegation/assembly connectors that connect the server (provide-port on SWC) through to the client (require-port on SWC).

[constr_3264] Server side ClientServerToSignalMappings in case of a n:1 inter-ECU client-server communication

Imposition time: IT_SysDesc

⌈If within the System with category SYSTEM_DESCRIPTION or SYSTEM_EXTRACT the ClientServerToSignalMappings for inter-ECU n:1 client-server communication are placed on the provider (server) side, then each of these ClientServerToSignalMappings shall (in the hierarchy of SwComponentPrototypes) refer to a "unique communication path" w.r.t. the EcuInstances the client SwComponentPrototypes are mapped to.⌋

Note: A "unique communication path" has the property that, starting from the ClientServerOperation of a PortPrototype, a sequence of DelegationSwConnectors and AssemblySwConnectors leads to the client side and terminates at either at most one PortPrototype that is owned by the AtomicSwComponentType of the client’s SwComponentPrototype or, if the path terminates at more than one PortPrototype, then the following shall hold: The clients’ SwComponentPrototypes typed by AtomicSwComponentTypes owning these PortPrototypes shall be mapped to the same EcuInstance and the client identifier is used to distinguish the different clients (see [TPS_SYST_01087]).

The following example scenarios will show at which PortPrototypes the ClientServerToSignalMappings are allowed to be specified in a System with category SYSTEM_DESCRIPTION or SYSTEM_EXTRACT to derive an ECU_EXTRACT.

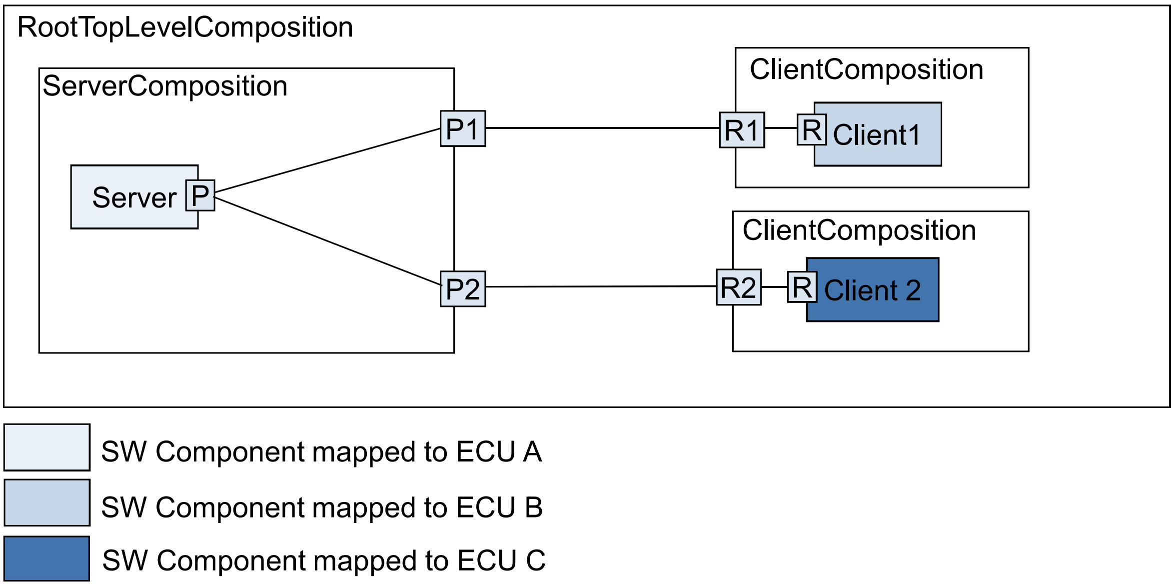

Figure 14.2: Client Server Scenario 1

For the scenario described in figure 14.2 the following statements apply:

- `ClientServerToSignalMapping`s for the provide-port Server.P are ambiguous and thus [constr_3243] exists to forbid this situation.
- `ClientServerToSignalMapping`s are permitted for ClientComposition.R1/ClientComponsition.R2 and Client1.R/Client2.R (client-side) or for ServerComposition.P1/ServerComposition.P2 (provider-side) since there is no ambiguity.

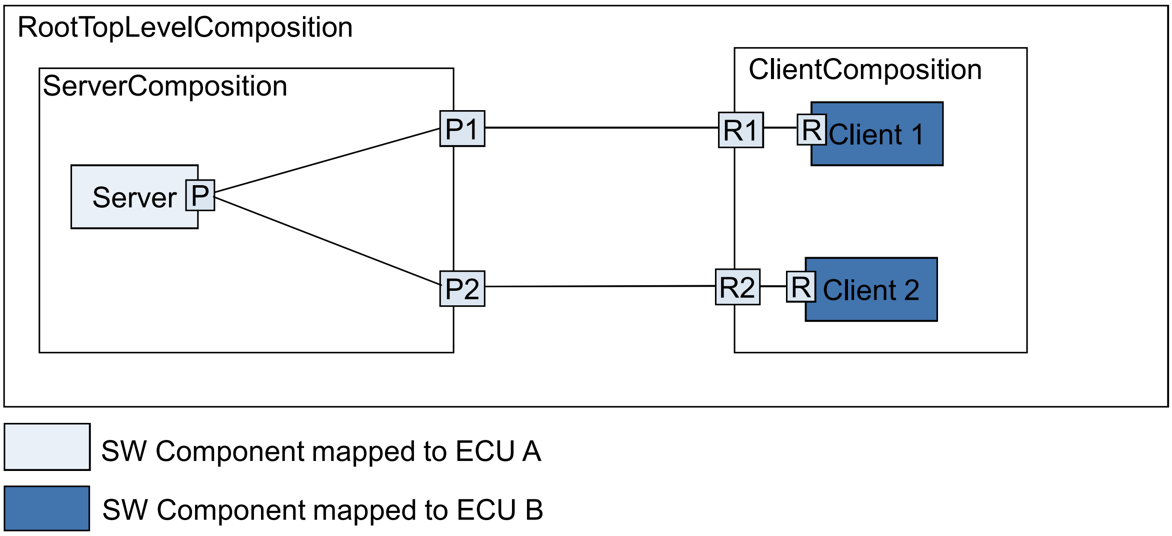

Figure 14.3: Client Server Scenario 2

For the scenario described in figure 14.3 the following statements apply:

- ClientServerToSignalMappings for the provide-port Server.P are not ambiguous (since although there is fork in the communication path, both sub-paths end up at the same ECU).
- ClientServerToSignalMappings are permitted for ClientComposition.R1/ClientComponsition.R2 and Client1.R/Client2.R (client-side) or for ServerComposition.P1/ServerComposition.P2 (provider-side) since there is no ambiguity.

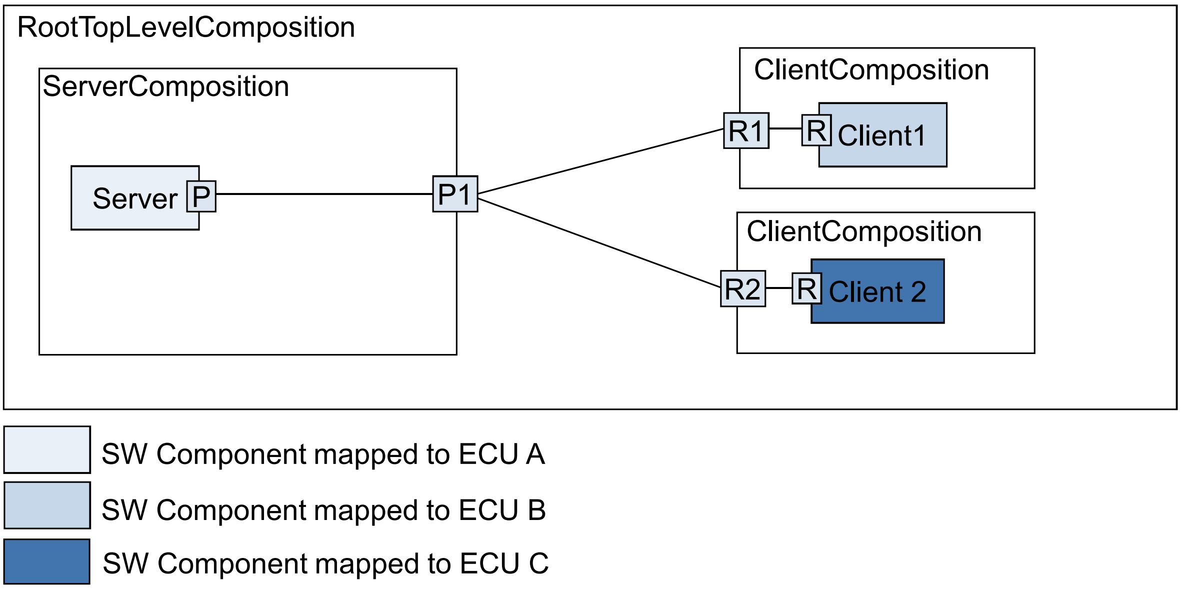

Figure 14.4: Client Server Scenario 3

For the scenario described in figure 14.4 the following statements apply:

- ClientServerToSignalMappings for the provide-ports Server.P and ServerComposition.P1 are ambiguous and thus [constr_3243] exists to forbid this situation.
- ClientServerToSignalMappings are permitted for ClientComposition.R1/ClientComposition.R2 and Client1.R/Client2.R (client-side) since there is no ambiguity.

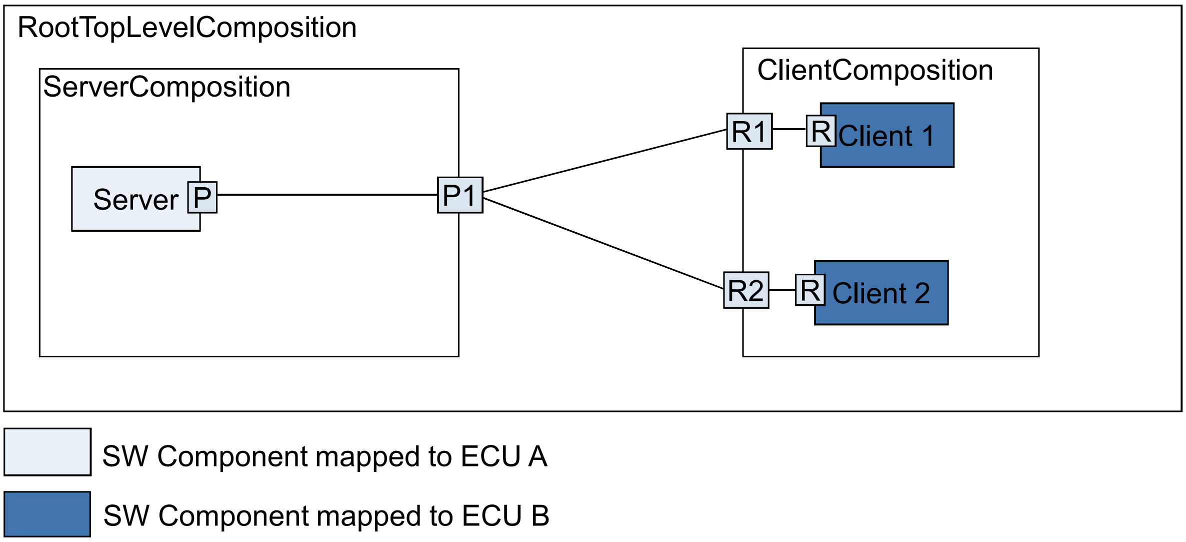

Figure 14.5: Client Server Scenario 4

For the scenario described in figure 14.5 the following statements apply:

- ClientServerToSignalMappings for the provide-ports Server.P and ServerComposition.P1 are not ambiguous (since although there is fork in the communication path, both sub-paths end up at the same ECU).
- ClientServerToSignalMappings are permitted for ClientComposition.R1/ClientComponsition.R2 and Client1.R/Client2.R (client-side) or for ServerComposition.P1/ServerComposition.P2 (provider-side) since there is no ambiguity.

[TPS_SYST_01145] PortInterfaceMappings in the ECU Extract ⌈In the System with category ECU_EXTRACT the missing PortInterfaceMappings on the complementary side needs to be supplemented to DelegationSwConnectors.⌋

[constr_5328] Ecu Extract shall only contain outerPort DataMappings

Imposition time: IT_EcuExt

⌈The System with category ECU_EXTRACT shall only contain DataMappings for VariableDataPrototypes, ClientServerOperations or Triggers that are referenced in the context of a PortPrototype of the SwComponentType that in turn is referenced by the RootSwCompositionPrototype.⌋

In other words the ECU_EXTRACT shall not contain any DataMappings that are defined in the context of SwComponentPrototypes that are included in the RootSwCompositionPrototype. Only the outerPort DataMappings defined in the context of RootSwCompositionPrototype are considered by the RTE.

Figure 14.6 shows how the System with category ECU_EXTRACT for ECU A of the SW composition that is defined in figure 13.3 would look like: Only those SwComponentPrototypes are included that are mapped to ECU A. The hierarchy present in the System with category SYSTEM_DESCRIPTION has been flattened into CompositionSwComponentType 'EcuAFlatView', including newly created SwComponentPrototype 'A1E', 'A2E', 'B1E' and 'C1E' for the component instances mapped to ECU A.

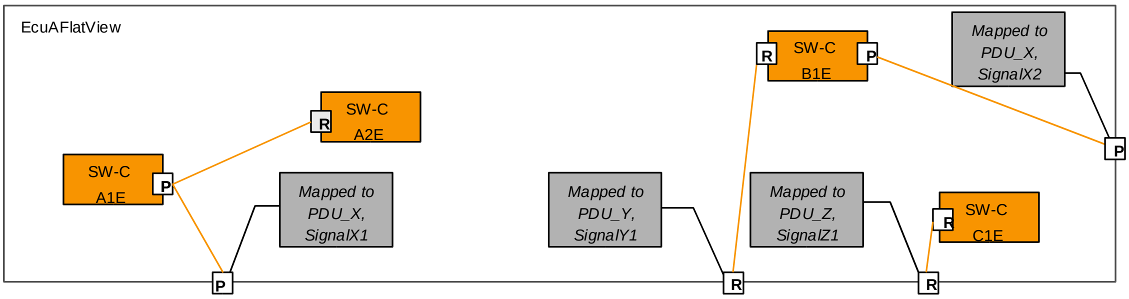

Figure 14.6: Example ECU extract for ECU A of above introduced composition

The SwConnectors to the outside ports (ECUFlatView composition ports) and SwConnectors that represent intra-ECU communication (in our example, only 'A1E' to 'A2E') are included. The VariableDataPrototypes and ClientServerOperations in the outside ports are mapped to SystemSignals. This DataMapping and the communication description is used to identify the source/destination of that data.

Furthermore, the relevant topology information and communication matrix have to be included, but they are out of scope of this example.

The problem that new mapping rules have to be added arises with the mapping to 'PDU_Y', 'SignalY1': Since SW component 'A3', which was referenced in the original mapping, is no longer included, the DataMapping needs a new VariableDataPrototype in a PortPrototype to reference to. In the example, the data of the required port of 'B1E' is referenced, so that the ECU generator has the information that 'B1E' receives the data via 'PDU_Y'.

14.2.4 Port Groups

A SwComponentType can optionally define PortGroups which allow to group PortPrototypes according to logical criteria, e.g. according to shared communication resources (see [4]). A PortGroup of a CompositionSwComponentType can be linked to "inner" PortGroups of the aggregated SwComponentPrototypes. Since the main purpose of this grouping is to configure the behavior of mode managers on an EcuInstance, this information shall be preserved and broken down into the System with category ECU_EXTRACT.

The resulting CompositionSwComponentType in the ECU flat view will contain a set of PortGroups which refer to the linked inner port groups of the SwComponentPrototypes with AtomicSwComponentType. To get to this result, the following steps shall be applied in the extraction process:

- Recursively ignore all PortGroups in CompositionSwComponentTypes in the hierarchical structure, which are not linked to any inner groups to be mapped on this EcuInstance.
- In the remaining structure of linked PortGroups find out the top level PortGroups (i.e. which are not referred by any higher level PortGroup on this EcuInstance) and put an element representing each top level PortGroup into the CompositionSwComponentType of the ECU flat view. This can result in name conflicts, which should be resolved by a suitable algorithm.
- Link these top level PortGroups to the inner PortGroups of the atomic component instances of the flat view according to the links found in the hierarchical structure. Naturally, the top level PortGroups in the ECU flat view are not directly referring any PortPrototypes and due to the first step they should be linked to at least one inner PortGroup.
- The PortGroups in SwComponentPrototypes with an AtomicSwComponentType on the EcuInstance should be unchanged.

14.2.5 Service Needs

Each software component might need services which are provided by the ECU Basic Software through AUTOSAR Services. ServiceNeeds are used to provide detailed information what the software component expects from the AUTOSAR Services when integrated on an actual ECU (see SWComponentTemplate [4] for more details). If an ECU Extract is created the following rules apply to the existing ServiceNeeds:

[constr_3068] DoIpPowerModeStatusNeeds in the category ECU_EXTRACT

Imposition time: IT_EcuExt

⌈If and only if DoIP (i.e. any of the subclasses of DoIpServiceNeeds are present) is used on an Ecu then the DoIpPowerModeStatusNeeds shall exist exactly once in a System of category ECU_EXTRACT.⌋

[constr_1265] DoIpGidSynchronizationNeeds can only exist once per ECU_EXTRACT

Imposition time: IT_EcuExt

⌈Within the context of one System of category ECU_EXTRACT, there can only be at most one DoIpGidSynchronizationNeeds.⌋

[constr_1266] DoIpGidNeeds can only exist once per ECU_EXTRACT

Imposition time: IT_EcuExt

⌈Within the context of one System of category ECU_EXTRACT, there can only be at most one DoIpGidNeeds.⌋

[constr_1267] DoIpActivationLineNeeds can only exist once per ECU_EXTRACT

Imposition time: IT_EcuExt

⌈Within the context of one System of category ECU_EXTRACT, there can only be at most one DoIpActivationLineNeeds.⌋

[constr_3083] Exactly one AtomicSwComponentType on an EcuInstance may use GeneralCallbackEventDataChanged / GeneralCallbackEventStatusChange

Imposition time: IT_EcuExt

⌈The Dem only supports exactly one AtomicSwComponentType using GeneralCallbackEventDataChanged / GeneralCallbackEventStatusChange on one EcuInstance.⌋

[constr_3084] Service port in the role PowerTakeOff

Imposition time: IT_EcuExt

⌈Within the context of one EcuInstance, there can only be one service port that uses the role PowerTakeOff in the RoleBasedPortAssignment.role.⌋

[constr_3085] Service port in the role CallbackDCMRequestServices

Imposition time: IT_EcuExt

⌈Within the context of one EcuInstance, there can only be one service port that uses the role CallbackDCMRequestServices in the RoleBasedPortAssignment.role.⌋

14.3 Extending the ECU Software Composition

As explained in [4], Service Configuration takes place in ECU Configuration phase. In the ECU extract of the System, the Software Components and their ECU-internal connectors are represented as a flat set aggregated by RootSwCompositionPrototype as indicated in Figure 14.7.

ECU Configuration extends this aggregation by adding SwComponentPrototypes (each typed by a specific ServiceSwComponentType) and the required AssemblySwConnectors to the RootSwCompositionPrototype. This is possible without changing the initial artifacts of the ECU extract, because these aggregations are stereotyped as ≪atpSplitable≫ in the meta-model.

After this step, the RootSwCompositionPrototype (denoted by EcucValueCollection.ecuExtract.rootSoftwareComposition) represents the whole Software Composition on the given ECU. This collection includes both the software components mapped to the ECU **and** the necessary service components represented as one SwComponentPrototype for each AUTOSAR Service utilized on the given ECU.

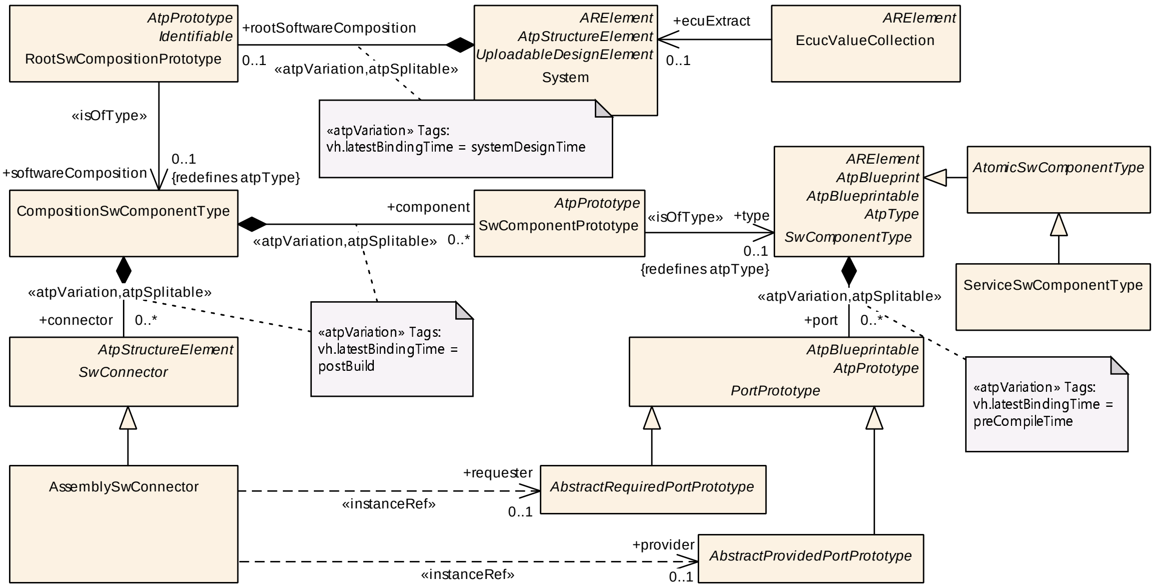

Figure 14.7: Usage of RootSwCompositionPrototype on an ECU

14.4 Communication

In explaining how SystemSignals are handled in the System with category ECU_EXTRACT, Section 14.2.3 touched on the topic of inter-ECU Communication. However, in order to enable the ECU Configuration of the COM-Stack, the relevant information of all layers of the AUTOSAR COM-Stack needs to be present in the System with category ECU_EXTRACT, including the central Communication classes ISignal, Pdu and Frame.

The above mentioned Communication elements have dependencies on each other, for ordinary COM-communication this means:

- Frames are assembled from one or more Pdus.
- ISignalIPdus carry their information in form of ISignals.

- ISignals as interaction points between RTE and COM refer to SystemSignals.

Note that the above list is not complete; TP and NM require additional elements. However, for the sake of clarity the following paragraphs describes the standard use case of a direct Signal-based communication between two EcuInstances. Once the handling of this case is understood, the additional model elements as NPdu, NmPdu, SystemSignalGroup etc. can be handled following the same basic principles.

For the System with category ECU_EXTRACT only the ECU-relevant subset of information present in the system-wide communication is to be considered. In order to establish this set of information, the dependencies in the list above are being followed.

14.4.1 Frame

In a complete System with category SYSTEM_DESCRIPTION, every outside communication of an EcuInstance will either be associated with an outgoing or and incoming Frame. The exact number and types of Frames to be received or sent by an EcuInstance is determined by the Communication Matrix (Chapter 6).

According to the selection rules for the Topology (14.1), the System with category ECU_EXTRACT contains all FrameTriggerings associated with Frames that are of any interest to the EcuInstance: If a particular FrameTriggering refers to a FramePort of type 'out' the associated Frame is to be sent by the EcuInstance, if it refers to an 'in' port the Frame is to be received. Therefore, the following selection rule applies:

- The System with category ECU_EXTRACT shall contain all Frame elements which are referenced by any included FrameTriggering.

14.4.2 PDU

Frames are assembled from one or more Pdus. In order to include all required Pdu elements, the following selection criteria apply:

- The System with category ECU_EXTRACT shall contain all Pdu elements which are referenced by any included Frame's PduToFrameMapping.
- The System with category ECU_EXTRACT shall contain all Pdu elements which are referenced by any included PduTriggering.
- For multiplexed Pdus, additionally all ISignalIPdus referenced by the MultiplexedIPdu's static and dynamic parts need to be included.

The second criterion is e.g. required in a pure post-build configuration scenario, where the frame-layout may not be completed at the time of System with category ECU_EXTRACT creation.

14.4.3 ISignals and ISignalGroups

ISignalIPdus carry their information in form of ISignals or ISignalGroups. In order to include all required ISignal and ISignalGroup elements, the following selection criteria apply:

- The System with category ECU_EXTRACT shall contain ISignal elements which are referenced by included ISignalIPdu's ISignalToIPduMapping. One exception are Pdu Gateways. Signal definitions that are not directly relevant for Gateways in case that the Pdu is routed as a whole (Pdu Routing) shall be omitted. See Section 14.4.5 for more details.
- The System with category ECU_EXTRACT shall contain all ISignal elements which are referenced by any included ISignalTriggering.
- The System with category ECU_EXTRACT shall contain ISignalGroup elements which are referenced by included ISignalIPdu's ISignalToIPduMapping. One exception are Pdu Gateways. Signal Group definitions that are not directly relevant for Gateways in case that the Pdu is routed as a whole (Pdu Routing) shall be omitted. See Section 14.4.5 for more details.
- The System with category ECU_EXTRACT shall contain all ISignalGroup elements which are referenced by any included ISignalTriggering.

Like in the case of the Pdu inclusion rules, the second and fourth criterion is required in scenarios with incomplete Pdu modeling due to post-build configurability of the communication matrix.

14.4.4 SystemSignal and SystemSignalGroup

Whereas the rules specified in Section 14.2.3 for the inclusion of SystemSignal comprise all SystemSignals that are being used by the Software Components in the ECU, the inclusion rules above stated for ISignalIPdus and ISignals may require the inclusion of additional SystemSignals. Also, strictly speaking both SystemSignals and SystemSignalGroup need to be considered. The complete inclusion rules for SystemSignals and SystemSignalGroups are:

- The System with category ECU_EXTRACT shall contain all SystemSignals and SystemSignalGroup elements which are referenced by any included DataMapping.
- The System with category ECU_EXTRACT shall contain all SystemSignal elements which are referenced by any included ISignal.
- The System with category ECU_EXTRACT shall contain all SystemSignalGroup elements which are referenced by any included ISignalGroup.

In addition on the receiving EcuInstance the following cases exist:

- only one SystemSignal out of the transmitted SystemSignalGroup is received: no SystemSignalGroup is required in the Ecu Extract of the receiving EcuInstance.
- more than one but not all SystemSignals out of the transmitted SystemSignalGroup are received: new SystemSignalGroup shall be created in the System with category ECU_EXTRACT of the receiving EcuInstance containing the received SystemSignals.
- all SystemSignals out of the transmitted SystemSignalGroup are received: the original SystemSignalGroup shall be the taken over to the System with category ECU_EXTRACT of the receiving EcuInstance.

14.4.5 Gateways

Gateways that refer the EcuInstance shall be included in the System with category ECU_EXTRACT. The complete inclusion rules for Gateways are:

- The System with category ECU_EXTRACT shall contain all FrameMapping elements that are aggregated by the Gateway element.
- The System with category ECU_EXTRACT shall contain all IPduMapping elements that are aggregated by the Gateway element.
- The System with category ECU_EXTRACT shall contain all ISignalMapping elements that are aggregated by the Gateway element.
- ISignal definitions that are not directly relevant for the Gateway in case that the Pdu containing these ISignals is routed as a whole (Pdu Routing) shall be omitted .
- ISignalGroup definitions that are not directly relevant for the Gateways in case that the Pdu containing these ISignalGroups is routed as a whole (Pdu Routing) shall be omitted .

14.4.6 TP configuration

The TP-configuration element TpConfig and all its associated elements shall be included into the System with category ECU_EXTRACT if the EcuInstance has an TpAddress configured in this TpConfig.

14.4.7 NM configuration

The Nm configuration part of the System with category ECU_EXTRACT shall include the NmEcu that references the included EcuInstance. In addition a NmCoordinator composed by this NmEcu shall be included. Furthermore any NmNode referenced by the NmCoordinator shall be included. For each included NmNode the composing NmCluster shall be included. For each included NmCluster the composing NmConfig shall be included.

14.5 Naming Issues

[TPS_SYST_05015] Naming conventions

Upstream requirements: RS_SYST_00053

⌈The definition of naming conventions may facilitate the avoidance of name clashes to the further degree. However, these naming conventions can only be defined on the model level and the System Template does not define any specific naming conventions.⌋

Please note that a detailed information about mechanisms to resolve naming conflicts is given in [3]: [TR_METH_03005], [TR_METH_03006], [TR_METH_03007], [TR_METH_03008], [TR_METH_03009], [TR_METH_03010].

14.5.1 Package Structure

As detailed in the sections above, extracting information from the System with category SYSTEM_DESCRIPTION into an System with category ECU_EXTRACT is a non-trivial transformation: While some of the model elements are simply copied verbatim into the System with category ECU_EXTRACT, it is additionally necessary to create new elements reducing parts of system-wide structures, most noticeably in flattening of the hierarchical VFB view to the ECU Flat View.

All such elements being created or modified in the process of generating the System with category ECU_EXTRACT shall reside in the same ARPackage. In order to avoid namespace conflicts with existing elements, the package shall exclusively be used for this purpose.

By creating derivation elements from elements originally contained in the System with category SYSTEM_DESCRIPTION package structure, duplications of names may occur. This kind of name clashes shall be resolved by a suitable naming algorithm (see section 14.5.3).

All Elements that are taken over from the System with category SYSTEM_DESCRIPTION unchanged (e.g. AtomicSwComponentType, PortInterface, ApplicationDataType, EcuInstance, CommunicationCluster) shall remain in their original packages.

ARElements not used in the System with category ECU_EXTRACT shall not be copied to the ECU Extract XML file.

In more detail, ARPackages taken over from System with category SYSTEM_DESCRIPTION will not be altered by the ECU extraction process, except that some ARElements will not be included in the actual XML file of the extract: ARElements which exist in the System with category SYSTEM_DESCRIPTION but have been stripped for the System with category ECU_EXTRACT are not actually deleted from their ARPackage, but merely are skipped in the XML file forming the extract. Note that having such a partial view on an ARPackage doesn't break the original ARPackage definition because the composition of PackageableElement, responsible for adding ARElements to ARPackage, is stereotyped ≪splitable≫; this means several XML files can contribute to an ARPackage, or in case of the ECU Extract an AUTOSAR description file may contain only a subset of the complete ARPackage.

14.5.2 Naming of Measurement and Calibration Data

The software component descriptions provide several means to declare data prototypes which have to be available for measurement and calibration (MCD) tools on the EcuInstance. Together with the System with category ECU_EXTRACT it is required to provide a list of references to the description of these data for further processing in the scope of the EcuInstance. In addition, the MCD tools need a unique name for each instance of such a data prototype. Since the data descriptions are part of the nested composition structure and are contained in reusable types (components or port interfaces), the system description itself does in general not provide unique names for those.

This means, providing such a list with references and unique names for MCD data is also a task of the ECU extractor tool. This list is part of the artifact ECU Flat Map, which is further explained below.

14.5.3 Naming of Derived Elements

When performing the extract process, name clashes may occur, necessitating a naming scheme for elements derived in ECU generation: By flattening the Software Composition hierarchy all component instances present on the considered EcuInstance are put in one ECU-wide software composition. Name clashes may occur for the following reasons:

1. SwComponentPrototypes taken from different Software Compositions are allowed to have identical short names in the hierarchical structure. As all SwComponentPrototypes will be located in the same ECU Flat View, the original name spaces separation no longer exists.
2. Multiple instances of the same CompositionSwComponentType are mapped to an EcuInstance: In this case, duplicates of all contained SwComponentPrototypes will be placed next to each other in the ECU flat composition.

3. The two mechanisms just mentioned may also lead to name clashes in AutosarDataPrototypes if their names shall be used as MCD data names. In addition, reuse of a PortInterface can also lead to name clashes if it provides data elements to be used by MCD.

4. The setup of PortGroups in the ECU flat view can result in name clashes, because two port groups originating from different component types (i.e. different name spaces) may be aggregated within the flat view.

Therefore the System with category ECU_EXTRACT generator shall take care that all elements derived or created during the extraction process have unique short names. These unique names shall be created in an initial step of the extraction process which leads to the creation of an initial ECU Flat Map. Some ways to satisfy this requirement may be:

- Use globally unique identifiers (GUID) for generating short names.
- Add a number to the original name; if done consistently the flat map approach makes this reproducible.
- Expand the name recursively by the names of the containing elements (e.g. compositions) until is is unique.
- Allow human interaction (this may be combined with an initially proposed name expansion).

The creation of a new short name is compulsory only if otherwise a clash would occur.

[constr_2025] Uniqueness of symbol attributes

Imposition time: IT_EcuExt

⌈With the exception of RunnableEntities that are subject to [constr_1234] (RunnableEntities owned by NvBlockSwComponentTypes), in the context of a single EcuInstance the values of the RunnableEntity.symbol in combination with the attribute symbol of the meta-class SymbolProps owned by AtomicSwComponentType of all deployed RunnableEntities shall be unique such that no two (or more) combinations of RunnableEntity.symbol and the symbol of the meta-class SymbolProps owned by AtomicSwComponentType in the role symbolProps share the same value.⌋

14.5.4 Re-use of short names assigned in previous iterations

As described in the previous section, potential name clashes during ECU extraction shall be avoided by assigning unique names to the elements specifically created for the System with category ECU_EXTRACT and for the list of MCD data per EcuInstance. Considering the use case of iterative development (also see Section 14.6), the same names shall be assigned to existing elements in consecutive iterations. Elements which have been modified or newly introduced between two ECU extract iterations shall not use an existing short name. Additionally, the ECU extractor tool shall not re-use any short name used in any iteration from previous development phases if the meaning of the element is not exactly the same (i.e. the element's back reference into the System Configuration Description is not the same.)

14.6 ECU Extract in subsequent Cycles of Iterative Development

14.6.1 Traceability of model elements created in ECU Extract

For development scenarios in real life projects iterative development shall be supported.

The following use case shall be considered:

Changes in the System with category SYSTEM_DESCRIPTION require the recreation of an System with category ECU_EXTRACT. In the successive re-run of ECU configuration, ECU configuration parameters which were configured based on the previous System with category ECU_EXTRACT need to be maintained for those parts in the System with category ECU_EXTRACT that didn't change between iterations.

Consequently, there are two requirements on the extraction process:

- Elements that are present in both versions of the System with category SYSTEM_DESCRIPTION shall not change their short names between the two ECU Extracts either.
- If changes between the two versions of the System with category SYSTEM_DESCRIPTION lead to the creation of new model elements in the System with category ECU_EXTRACT, then these newly created elements shall have new names that have not been used in previous iterations of the System with category ECU_EXTRACT. (See also Section 14.5.4).

In order to fulfill these requirements, a back-tracing of the relevant model elements in the System with category ECU_EXTRACT to their counterparts in the System with category SYSTEM_DESCRIPTION shall be established. Based on these back references, short names shall consistently be re-used in iterations. Relevant elements are all those which potentially have been modified in the extraction process.

All back-tracing references are collected in one central table per System with category ECU_EXTRACT based on the meta-class FlatMap. This table collects "instance" entries for each Ecu Extract element that is being created in the System with category ECU_EXTRACT transformation and for each MCD data object that has to be available in the EcuInstance. These entries are called FlatInstanceDescriptor.

Each mapping entry owns two references per mapped element, one reference pointing to the target element in the System with category ECU_EXTRACT, the other one pointing to the origin upstream description (for more details about allowed upstream description see FlatInstanceDescriptor.upstreamReference). Both of these references are deep “instance" references, requiring a tuple of context/target description.

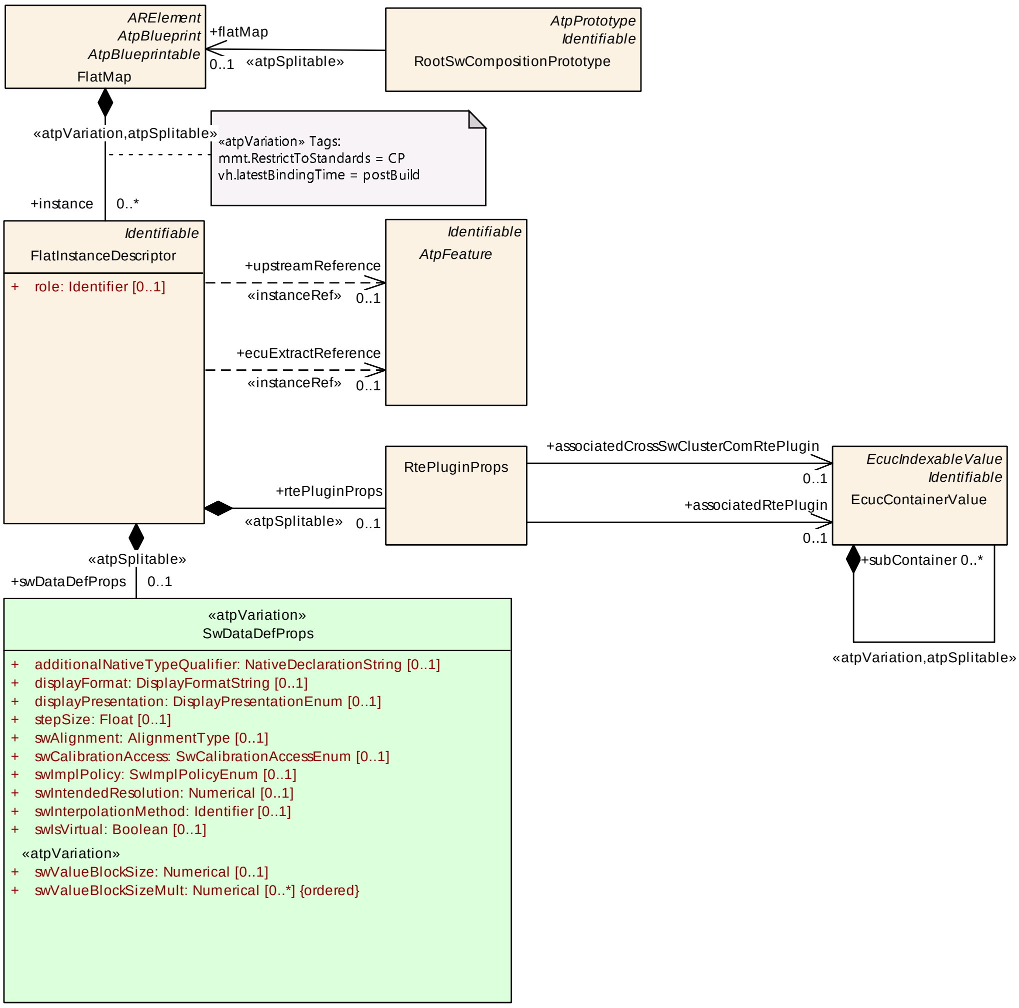

Figure 14.8: Flat Map (CommonStrucure: FlatMap)

Class	**FlatMap**
Package	M2::AUTOSARTemplates::CommonStructure::FlatMap
Note	Contains a flat list of references to software objects. This list is used to identify instances and to resolve name conflicts. The scope is given by the RootSwCompositionPrototype for which it is used, i.e. it can be applied to a system, system extract or ECU-extract. An instance of FlatMap may also be used in a preliminary context, e.g. in the scope of a software component before integration into a system. In this case it is not referred by a RootSwComposition Prototype. **Tags:** atp.recommendedPackage=FlatMaps
Base	*ARElement*, *ARObject*, *AtpBlueprint*, *AtpBlueprintable*, *CollectableElement*, *Identifiable*, *Multilanguage Referrable*, *PackageableElement*, *Referrable*

▽

△

Class	FlatMap			
Aggregated by	ARPackage.element			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
instance	FlatInstanceDescriptor	*	aggr	A descriptor instance aggregated in the flat map. The variation point accounts for the fact, that the system in scope can be subject to variability, and thus the existence of some instances is variable. The aggregation has been made splitable because the content might be contributed by different stakeholders at different times in the workflow. Plus, the overall size might be so big that eventually it becomes more manageable if it is distributed over several files. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=instance.shortName, instance.variation Point.shortLabel vh.latestBindingTime=postBuild

Table 14.1: FlatMap

Class	FlatInstanceDescriptor			
Package	M2::AUTOSARTemplates::CommonStructure::FlatMap			
Note	Represents exactly one node (e.g. a component instance or data element) of the instance tree of a software system. The purpose of this element is to map the various nested representations of this instance to a flat representation and assign a unique name (shortName) to it. Use cases: • Specify unique names of measurable data to be used by MCD tools • Specify unique names of calibration data to be used by MCD tool • Specify a unique name for an instance of a component prototype in the ECU extract of the system description Note that in addition it is possible to assign alias names via AliasNameAssignment.			
Base	*ARObject*, *Identifiable*, *MultilanguageReferrable*, *Referrable*			
Aggregated by	FlatMap.instance			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
ecuExtract Reference	AtpFeature	0..1	iref	Refers to the instance in the ECU extract. This is valid only, if the FlatMap is used in the context of an ECU extract. The reference shall be such that it uniquely defines the object instance. For example, if a data prototype is declared as a role within an SwcInternalBehavior, it is not enough to state the SwcInternalBehavior as context and the aggregated data prototype as target. In addition, the reference shall also include the complete path identifying instance of the component prototype and the Atomic SoftwareComponentType, which is refered by the particular SwcInternalBehavior. **Tags:** xml.sequenceOffset=40 **InstanceRef implemented by:** AnyInstanceRef

▽

△

Class	**FlatInstanceDescriptor**			
role	Identifier	0..1	attr	The role denotes the particular role of the downstream memory location described by this FlatInstanceDescriptor. It applies to use case where one upstream object results in multiple downstream objects, e.g. ModeDeclaration GroupPrototypes which are measurable. In this case the RTE will provide locations for current mode, previous mode and next mode.
rtePluginProps	RtePluginProps	0..1	aggr	The properties of a communication graph with respect to the utilization of RTE Implementation Plug-in. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=rtePluginProps
swDataDef Props	SwDataDefProps	0..1	aggr	The properties of this FlatInstanceDescriptor. **Stereotypes:** atpSplitable **Tags:** atp.Splitkey=swDataDefProps
upstream Reference	AtpFeature	0..1	iref	Refers to the instance in the context of an "upstream" description, which could be: the SYSTEM_ DESCRIPTION, or SYSTEM_EXTRACT, or ECU_ SYSTEM_DESCRIPTION, or SW_CLUSTER_SYSTEM_ DESCRIPTION, or the basic software module description (in this case only the target reference of the AnyInstance Ref is needed), or (if a flat map is used in preliminary context) a description of an atomic component or composition. This reference is optional in case the flat map is used in ECU context. The reference shall be such that it uniquely defines the object instance in the given context. For example, if a data prototype is declared as a role within an SwcInternal Behavior, it is not enough to state the Swc Internal Behavior as context and the aggregated data prototype as target. In addition, the reference shall also include the complete path identifying the instance of the component prototype that contains the particular instance of Swc InternalBehavior. **Tags:** xml.sequenceOffset=20 **InstanceRef implemented by:** AnyInstanceRef

Table 14.2: FlatInstanceDescriptor

[constr_9300] Existence of FlatMap.instance

Imposition time: IT_EcuExt

⌈For each FlatMap, at least one FlatInstanceDescriptor shall be aggregated by FlatMap in the role instance.⌋

[TPS_SYST_01000] FlatInstanceDescriptor roles

Upstream requirements: RS_SYST_00003, RS_SYST_00027

⌈If a ModeDeclarationGroupPrototype is measurable the FlatMap shall contain three entries where the particular roles are set to

- CURRENT_MODE specifies the FlatInstanceDescriptor applicable for current mode value of the ModeDeclarationGroupPrototype

- PREVIOUS_MODE specifies the FlatInstanceDescriptor applicable for previous mode value of the ModeDeclarationGroupPrototype
- NEXT_MODE specifies the FlatInstanceDescriptor applicable for next mode value of the ModeDeclarationGroupPrototype

Please note that these entries may exist in a FlatMap even if the ModeDeclarationGroupPrototype is not measurable.⌋

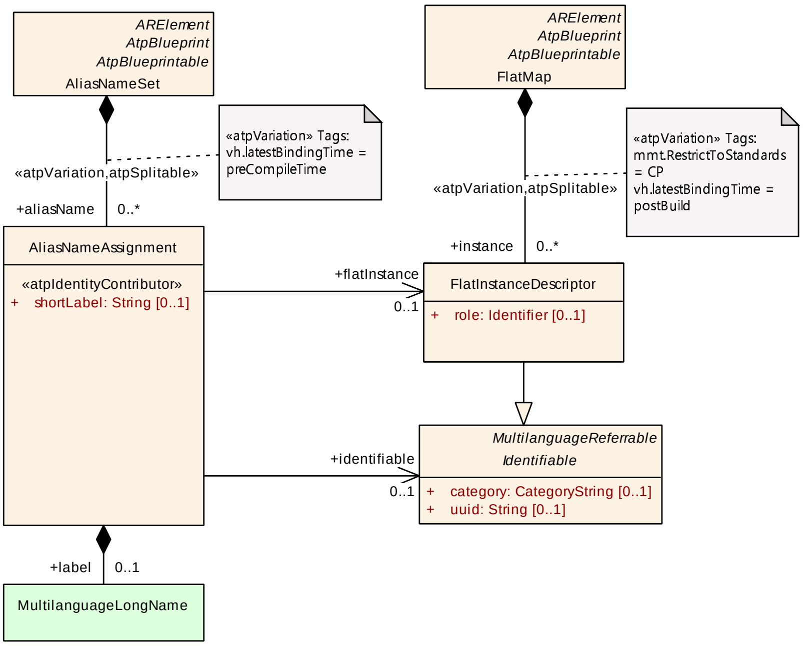

Figure 14.9: Alias Name Assignment (CommonStrucure: AliasNameAssignment)

Class	AliasNameSet			
Package	M2::AUTOSARTemplates::CommonStructure::FlatMap			
Note	This meta-class represents a set of AliasNames. The AliasNameSet can for example be an input to the A2L-Generator. **Tags:** atp.recommendedPackage=AliasNameSets			
Base	*ARElement*, *ARObject*, *AtpBlueprint*, *AtpBlueprintable*, *CollectableElement*, *Identifiable*, *Multilanguage Referrable*, *PackageableElement*, *Referrable*			
Aggregated by	ARPackage.element			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
aliasName	AliasNameAssignment	*	aggr	AliasNames contained in the AliasNameSet. **Stereotypes:** atpSplitable; atpVariation **Tags:** atp.Splitkey=aliasName.shortLabel, aliasName.variation Point.shortLabel vh.latestBindingTime=preCompileTime

Table 14.3: AliasNameSet

Class	AliasNameAssignment			
Package	M2::AUTOSARTemplates::CommonStructure::FlatMap			
Note	This meta-class represents the ability to associate an alternative name to a flat representations or an Identifiable. The usage of this name is defined outside of AUTOSAR. For example this name can be used by MCD tools or as a name for component instances in the ECU extract. Note that flatInstance and identifiable are mutually exclusive.			
Base	*ARObject*			
Aggregated by	AliasNameSet.aliasName			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
flatInstance	FlatInstanceDescriptor	0..1	ref	Assignment of a unique name to a flat representation. **Tags:** xml.sequenceOffset=60
identifiable	Identifiable	0..1	ref	Assignment of a unique name to an Identifiable. **Tags:** xml.sequenceOffset=50
label	MultilanguageLong Name	0..1	aggr	This represents an "Alias LongName". **Tags:** xml.sequenceOffset=20
shortLabel	String	0..1	attr	This attribute represents the alias name. It is modeled as string because the alias name is used outside of AUTOSAR and therefore no naming conventions can be applied within AUTOSAR. **Stereotypes:** atpIdentityContributor **Tags:** xml.sequenceOffset=10

Table 14.4: AliasNameAssignment

[constr_9301] Existence of AliasNameAssignment.shortLabel

Imposition time: IT_EcuExt

⌈For each AliasNameAssignment, the attribute shortLabel shall exist.⌋

During the ECU extraction process, the ECU FlatMap will be processed in the following steps:

1. Create the entries shortName and upstreamReference of the FlatMap or, if a previous version exists, try to reuse them. Resolve name conflicts.
2. Generate the ECU Software Composition.
3. Create the entries ecuExtractReference of the ECU FlatMap.

More details are define be the AUTOSAR methodology, see [3]. The methodology also allows to have a FlatMap for the whole system. This System FlatMap can be created and maintained independently from the ECU extraction process, but can be used as an input for the creation of the ECU FlatMap.

[constr_3378] Maximal one AliasNameAssignment allowed per FlatInstanceDescriptor

Imposition time: IT_EcuExt

⌈In a given instance of AliasNameSet in the bound system there shall be at most one aliasName per FlatInstanceDescriptor.⌋

14.6.2 Mapping of AUTOSAR attributes to ASAM ASAP2

With the MC Support information AUTOSAR builds a bridge to tools processing ASAM ASAP2 files. In order to support the interoperability of converter tools the following mapping of AUTOSAR attributes to ASAM ASAP2 [20] (also known as "A2l" respectively "ASAM MCD 2MC") is recommended:

- If the FlatInstanceDescriptor references DataPrototypes:

  FlatInstanceDescriptor.shortName ->
  MEASUREMENT Name
  CHARACTERISTIC Name

  FlatInstanceDescriptor.(longName + desc |upstreamReference.desc) ->
  MEASUREMENT LongIdentifier
  CHARACTERISTIC LongIdentifier

  AliasNameAssignment.shortLabel ->
  MEASUREMENT [-> DISPLAY_IDENTIFIER]
  CHARACTERISTIC [-> DISPLAY_IDENTIFIER]

  AliasNameAssignment.label(if provided) +
  FlatInstanceDescriptor.(desc |upstreamReference.desc) ->
  MEASUREMENT LongIdentifier
  CHARACTERISTIC LongIdentifier

- If AliasNameAssignment references a SwSystemconstant:

  AliasNameAssignment.shortLabel ->
  SYSTEM_CONSTANT -> Name for SwSystemconstants

- If AliasNameAssignment references a Unit:

  AliasNameAssignment.shortLabel ->
  UNIT -> Name for Units

14.6.3 Assigning communication graphs to RTE Implementation Plug-Ins

When RTE Implementation Plug-Ins are used to modularize the RTE implementation, it's required to decide which communication graphs are implemented by the RTE or by an specific RTE Implementation Plug-In. Thereby an RTE Implementation Plug-In is a part of the overall RTE implementation which is not provided by the RTE Generator but from an additional source (e.g. a Plug-In Generator or a manually implemented source code).

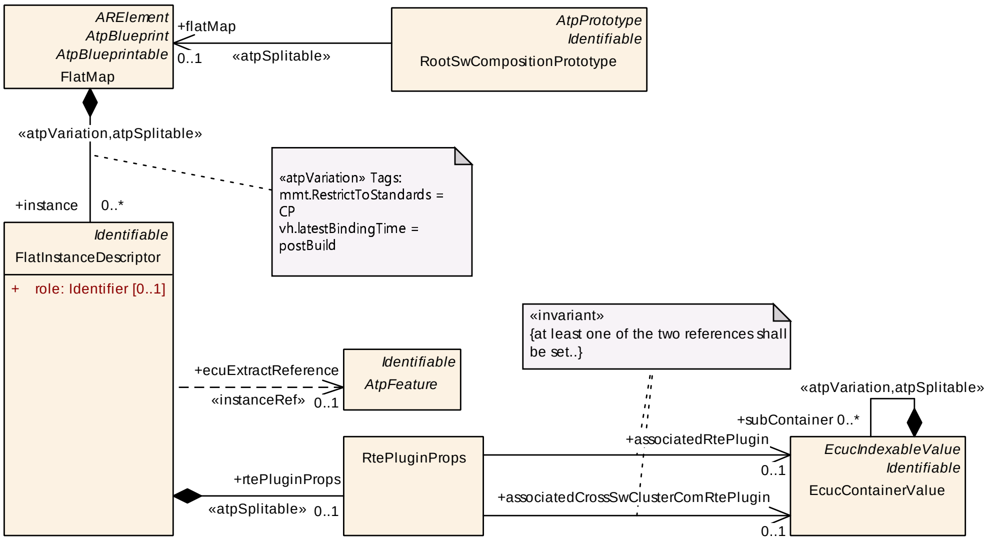

Figure 14.10: ECU Flat Map and rtePluginProps

Class	**RtePluginProps**			
Package	M2::AUTOSARTemplates::CommonStructure::FlatMap			
Note	The properties of a communication graph with respect to the utilization of RTE Implementation Plug-in.			
Base	*ARObject*			
Aggregated by	FlatInstanceDescriptor.rtePluginProps			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
associated CrossSwCluster ComRtePlugin	EcucContainerValue	0..1	ref	This associates a communication graph to a specific RTE Implementation Plug-in handling cross Software Cluster communication.
associatedRte Plugin	EcucContainerValue	0..1	ref	This associates a communication graph to a specific RTE Implementation Plug-in handling local Software Cluster communication or communication in a non-cluster ECU.

Table 14.5: RtePluginProps

This assignment is described with the FlatInstanceDescriptor.rtePluginProps, where the RtePluginProps.associatedRtePlugin or RtePluginProps.associatedCrossSwClusterComRtePlugin references the EcucContainerValue representing the identity of an RTE Implementation Plug-In.

Assigning an communication graphs has following underlying semantic:

[TPS_SYST_02197] Assigning communication graphs to RTE Implementation Plug-Ins

Upstream requirements: RS_SYST_00057

⌈The FlatInstanceDescriptor.ecuExtractReference points to an instance of a VariableDataPrototype and the FlatInstanceDescriptor.rtePluginProps.associatedRtePlugin or RtePluginProps.associatedCrossSwClusterComRtePlugin references the EcucContainerValue which defines the identity of the RTE Implementation Plug-In. This assigns the full communication graph to the specific RTE Implementation Plug-Ins represented by according EcucContainerValue.⌋

For instance the FlatInstanceDescriptor.ecuExtractReference points to instance of a VariableDataPrototype defined by the AnyInstanceRef using

- contextElement: RootSwCompositionPrototype
- contextElement: SwComponentPrototype
- contextElement: PPortPrototype
- target: VariableDataPrototype

According the AUTOSAR Meta-Model various further model elements are exist to describe the complete communication graph, for instance with the means of AssemblySwConnectors, SwComponentType.ports, RunnableEntitys and VariableAccesses. Nevertheless all such related elements of this communication graph are addressed by this single FlatInstanceDescriptor and all access of ExecutableEntitys to this communication graph are handled by the associated RTE Implementation Plug-In.

[constr_3458] FlatInstanceDescriptor.rtePluginProps shall only reference a EcucContainerValue representing a RteRipsPlugin

Imposition time: IT_EcuExt

⌈FlatInstanceDescriptor.rtePluginProps shall only reference an EcucContainerValue which defines the identity of the RTE Implementation Plug-In. This requires that the according EcucContainerValue's definition references a EcucContainerDef having a destinationUri set to /AUTOSAR/EcucDestinationUriDefSets/RteRipsUriDefSet/RteRipsPlugin⌋

[constr_5175] RtePluginProps shall reference at least one EcucContainerValue representing a RteRipsPlugin

Imposition time: IT_EcuExt

⌈If a FlatInstanceDescriptor owns are RtePluginProps this RtePluginProps shall define the associatedRtePlugin reference and/or the associatedCrossSwClusterComRtePlugin reference.⌋

To support different work-flows the FlatInstanceDescriptor.rtePluginProps is defined as ≪atpSplitable≫. Therefore it's possible the do the assignment of communication graphs immediately during the creation of the ECU Flat Map or in a second processing step after the ECU Flat Map is already created.

Further information, specifications, and applicable constraints on assignments of communication graphs are provided in the document SWS RTE [40] at which specific anchor points of an communication graphs the assignment shall be described.

Some further notes about the chosen modeling pattern

In general it is an unusual pattern, that a meta class not being related to ECU configuration references an EcucContainerValue. But the FlatInstanceDescriptor of the ECU Extract is in any case closely related to the configuration of the ECU. Furthermore in case of data conversion it's mandatory to provide for each different representation a FlatInstanceDescriptor for the communication graph. Further information about such configurations is provided in the document SWS RTE [40].

The alternative approach to describe the RTE Implementation Plug-In as meta class is not the right approach since only very few properties of RTE Implementation Plug-Ins are standardized. There is also no need to exchange information between different development parties about those properties. Due to this reason RTE Implementation Plug-Ins are described by the means of ECU Configuration elements.

The alternative approach to model the relationship between FlatInstanceDescriptors and the container which represents the RTE Implementation Plug-In with a mapping pattern was rejected due to the very high number of expected configuration elements.

14.7 Variant Handling in ECU Extract

The System Template supports the creation of variants in many of its model elements. Depending on the binding time, some of this variability may have been already resolved within the System with category SYSTEM_DESCRIPTION at the time of creating the System with category ECU_EXTRACT, and a cleanup step may have removed some of the complexity by removing the out-configured variability.

If however binding of a concrete variation condition happens in a later stage of the AUTOSAR methodology (e.g. during ECU Configuration or even post build), or if for other process reasons such a cleanup step is not applicable, the variability needs to be carried over to the System with category ECU_EXTRACT.

14.7.1 System Constants

In the AUTOSAR variant handling concept, SwSystemconst represents a variant selector which needs to have its value assigned latest at binding time of any expression which refers to it. Such a value assignment may be done literally using a fixed value, or by specifying a formula, depending on the values of other variant selectors. The elements to do this are collected in a SwSystemconstantValueSet, aggregating individual value assignment expressions in the form of SwSystemconstValue.

In the System with category ECU_EXTRACT, all SwSystemconst elements are included that influence its variable content. In detail the following rules for the inclusion of SwSystemconst apply:

- System with category ECU_EXTRACT shall contain all SwSystemconst elements that are being referenced directly by variable elements contained in the System with category ECU_EXTRACT.
- Additionally, whenever a SwSystemconst's value is assigned indirectly using an SwSystemconstValue's ConditionByFormula expression, each SwSystemconstValue referred to in the assignment formula needs to be included, too. As such assignments may be nested in multiple levels, the whole directed acyclic graph of SwSystemconst elements influencing the System with category ECU_EXTRACT variability need to be included.

Additionally to the SwSystemconst elements also all relevant SwSystemconstValue assignments need to be included. As they are aggregated by SwSystemconstantValueSet, the whole Value Set is included whenever one of its SwSystemconstValue assignments is relevant for the System with category ECU_EXTRACT.

Note: Typically, the assignment of Variants ("Binding") will be done in a Variant Configuration work product, separate from the actual System with category ECU_EXTRACT. In this case, the relevant information from the Variant Configuration also needs to be extracted and delivered in combination with the System with category ECU_EXTRACT. From the model point of view it doesn't matter whether System with category ECU_EXTRACT and Variant Configuration are contained in the same file or in separate files.

14.7.2 Nested Whole/Part class variants

In case of flattening the hierarchical VFB view to the ECU flat view representation, the case may appear that one conditional SwComponentPrototype is nested within another SwComponentPrototype depending on another variance condition. As the resulting ECU flat view only has a flat representation of SwComponentPrototypes, such a double condition needs to be resolved to a single condition in the resulting SwComponentPrototypes.

In this case, the variation condition formula needs to be altered such that the two (or more) individual conditions are combined in a boolean AND function.

14.7.3 Multiple instances of calibration parameters in system scope

Use case: In complex systems the problem occurs that parameter values may depend on the configuration of the vehicle due to functional side effects. E.g. the calibration of a lambda sensor depends from the kind of transmission due to mechanical impacts (e.g due to additional / different curvatures in the exhaust pipe)

The difficulty is that those dependencies are typically detected after design of the software components and shall not change the software component design. Furthermore this is typical use case for post build variability since the ECU SW should not change due to environmental variability.

[TPS_SYST_02029] Multiple ParameterDataPrototype instances in an EcuExtract ⌈It shall be possible to instruct the RTE Generator to provide various instances for a ParameterDataPrototype in the System with category ECU_EXTRACT. Therefore one FlatInstanceDescriptor per expected data instance has to point to the ParameterDataPrototype as an atpTarget.⌋

[constr_3114] FlatInstanceDescriptors pointing to the same ParameterDataPrototype shall have different postBuildVariantConditions

Imposition time: IT_EcuExt

⌈FlatInstanceDescriptors that are pointing as an atpTarget to the same ParameterDataPrototype instance shall have different postBuildVariantConditions.⌋

Note: When several instances of a ParameterDataPrototype are created it shall be ensured that at most one parameter instance is active in a post build variant.

[constr_3115] FlatInstanceDescriptors pointing to the same ParameterDataPrototype instance

Imposition time: IT_EcuExt

⌈When several FlatInstanceDescriptors point to the same ParameterDataPrototype instance as an atpTarget in the context of a ParameterInterface the different FlatInstanceDescriptors shall point to the PPortPrototype of the owning ParameterSwComponentType. In this case the PPortPrototype typed by the ParameterInterface is part of the context of the according AnyInstanceRef.⌋

Please note that the individual FlatInstanceDescriptors are utilized to provide unique names for the MCD tool as well as individual CalibrationParameterValues typically refer to the FlatInstanceDescriptors to provide instance specific initialization values.

15 Supported special use-cases

The description means of the communication matrix in the System Template potentially support a variety of use-cases. Some combinations of description means are explicitly ruled-out by semantical constraints. But the remaining space for the possible descriptions is so huge, that certain use-cases are actually not supported by tool-vendors because they did not consider them. This chapter describes special use-cases that can be specified in the System Template in order to get a harmonized support by tools.

15.1 Support of sending / receiving same Can/Flexray Frame on same channel (Pdu Gateway Use-Case)

Description: The System Template supports the definition of a communication where the same Can/Flexray FrameTriggering is sent and received on the same PhysicalChannel of one Pdu Gateway EcuInstance.

Rationale: This use-case occurs in gateway EcuInstances which are used in several vehicle platforms.

Implementation: This usage shall be supported by defining one Frame and one FrameTriggering with different directions on the referenced FramePorts for the same PhysicalChannel. Also one Pdu and one PduTriggering with different directions on the referenced IPduPorts for the same PhysicalChannel shall be used.

Example: In figure 15.1 a sample network setup is shown. The ECU1 is designed to send the Frame_X on the PhysicalChannel. The ECU2, ECU3 and ECU4 do receive the information. But since ECU1 is optional, ECU4 is also designed to send the Frame_X on the network (in case ECU1 is not present). Please note that in in this example ECU4 is a gateway EcuInstance that is connected to an additional channel.

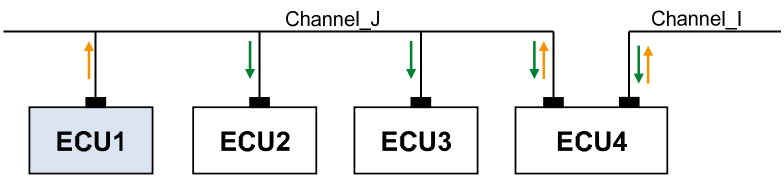

Figure 15.1: Example of network setup with one Frame being received and sent on the same ECU and channel

In the system description there exists one definition for the Frame_X and one FrameTriggering for the PhysicalChannel (figure 15.2). Each EcuInstance sending or receiving the FrameTriggering does define one FramePort per direction, thus for ECU4 there are two FramePorts defined.

For each Pdu mapped to the Frame there exists one definition for the Pdu_X and one PduTriggering for the PhysicalChannel. Each EcuInstance sending or receiving the Pdu does define one IPduPort per direction, thus for ECU4 there are two IPduPorts defined.

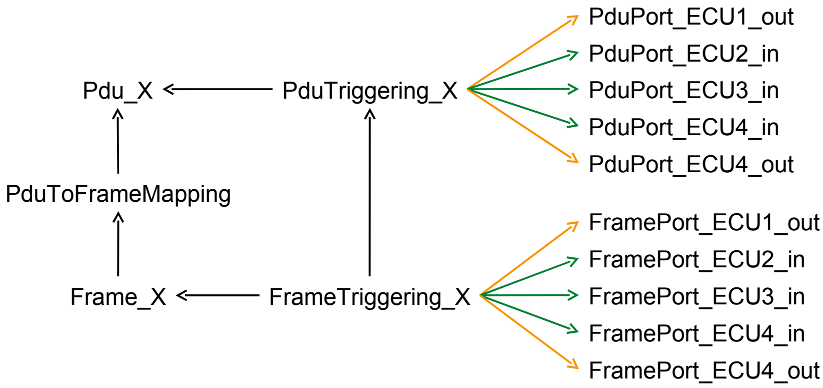

Figure 15.2: Structure to reflect the frame- and pdu-triggering setup of one Frame being received and sent by the same Gateway ECU

In case a System Extract / ECU Extract is build, only the relevant FramePorts and IPduPorts for the corresponding EcuInstance are extracted. Especially in case an additional EcuInstance is designed to send and receive the same Frame all the other ECU extracts will not be affected by this change.

15.2 Support of sending / receiving same Can/Flexray Frame on same channel (bidirectional routing in COM)

Description: The System Template supports the definition of a communication where the same Can/Flexray FrameTriggering is sent and received on the same PhysicalChannel of one EcuInstance and the content of this Frame is processed by an Application. Please note that this use case is only applicable for legacy communication over COM and not for communication over LdCOM.

Rationale: This use-case occurs in case of runtime variation where the same data is transmitted or received by the same ECU.

Implementation in a System Description: This use-case is supported with the following modelling:

- One Frame and one FrameTriggering with different directions on the referenced FramePorts for the same PhysicalChannel shall be defined.
- One Pdu and one PduTriggering with different directions on the referenced IPduPorts for the same PhysicalChannel shall be defined.

- One ISignal and one ISignalTriggering with different directions on the referenced ISignalPorts for the same PhysicalChannel shall be defined.

Please note that in case of a bidirectional routing on the ISignal level the COM Configuration (ComIPdus) needs to be derived from the PduTriggering and from IPduPorts.

Example: In figure 15.3 a sample network setup is shown. The same data (Frame_X) is transmitted by Ecu4 and by Ecu1 (runtime variation). Ecu4 is designed to send and to receive the Frame_X on the network. For Ecu2 and Ecu3 it is transparent from which sender (Ecu1 or Ecu4) the data is transmitted.

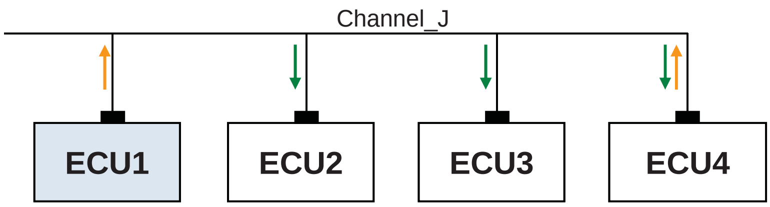

Figure 15.3: Example of network setup with one Frame being received and sent on the same ECU and channel

In the system description there exists one definition for the Frame_X and one FrameTriggering for the PhysicalChannel (figure 15.4). Each EcuInstance sending or receiving the FrameTriggering does define one FramePort per direction, thus for ECU4 there are two FramePorts defined.

For each Pdu mapped to the Frame there exists one definition for the Pdu_X and one PduTriggering for the PhysicalChannel. Each EcuInstance sending or receiving the Pdu does define one IPduPort per direction, thus for ECU4 there are two IPduPorts defined.

For each ISignal mapped to the Pdu there exists one definition for the Signal_X and one ISignalTriggering for the PhysicalChannel. Each EcuInstance sending or receiving the ISignal does define one ISignalPort per direction, thus for ECU4 there are two ISignalPorts defined.

Example 15.4 shows a System Description where only the DataMapping for the PPorts is defined. Please note that in the COM configuration a ComIPdu has a ComIPduDirection. Therefore two ComIPdus (Tx and Rx) need to be created from such a System Description.

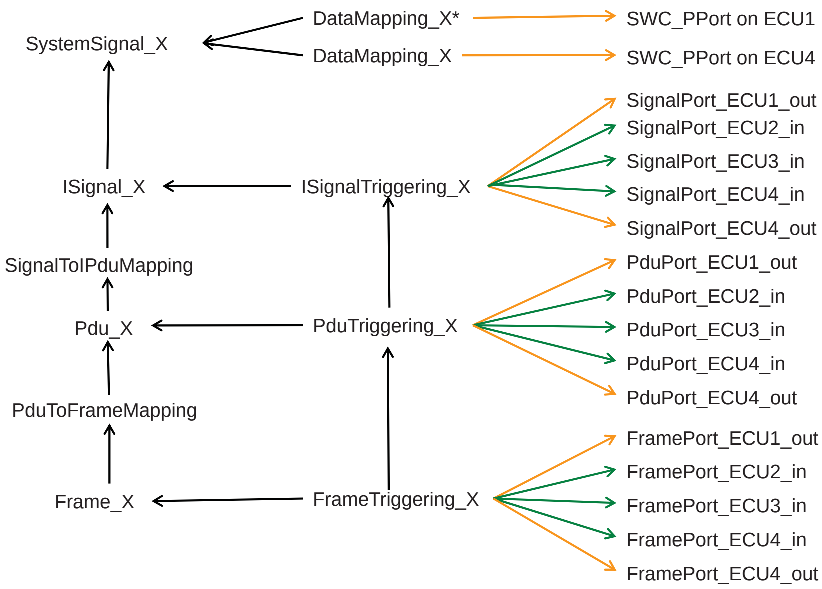

Figure 15.4: Structure to reflect the frame- and pdu-triggering setup of one Frame being received and sent on the same ECU and channel (System Description with ECU1, ECU2, ECU3 and ECU4)

In case a System Extract / ECU Extract is build, only the relevant FramePorts, IPduPorts and ISignalPorts for the corresponding EcuInstance are extracted. Especially in case an additional EcuInstance is designed to send and receive the same Frame all the other ECU extracts will not be affected by this change. Figure 15.5 shows a System Extract where only the description for ECU4 is available. Please note that in this example the VariableDataPrototype in the PPort and the VariableDataPrototype in the RPort of the Software Component are mapped to the same SystemSignal.

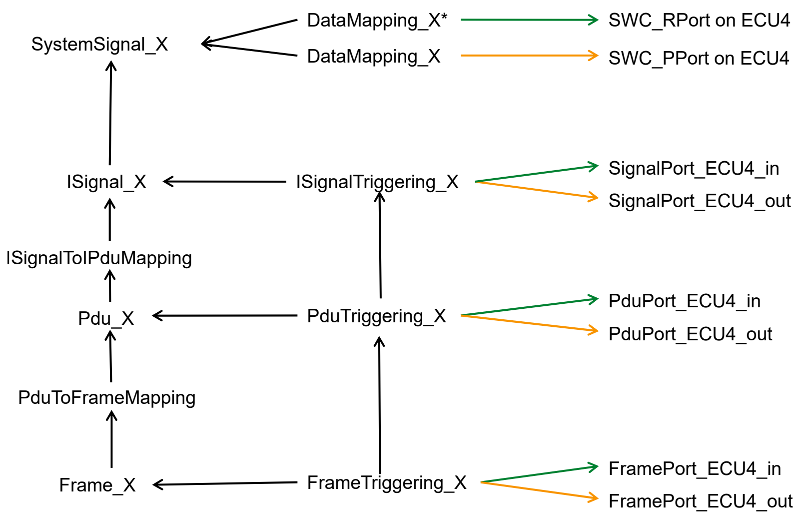

Figure 15.5: Structure to reflect the frame- and pdu-triggering setup of one Frame being received and sent on the same ECU and channel (System Extract with ECU4 only)

15.3 Support of dynamic CAN IDs

To support efficient diagnostics with on-board clients, efficient routing, and efficient SAE J1939 transport protocol and request handling, AUTOSAR provides access to dynamic CAN identifier parts in upper layers of the COM stack. This is achieved by appending parts of the identifier (or the complete identifier) as MetaData to the Pdu payload. The usage of MetaData is an Ecu Configuration decision. A System Description does not define whether MetaData shall be used or not.

The System Template uses the following attributes for the configuration of dynamic CAN IDs:

- The rxMask of a CanFrameTriggering defines the relevant bits in a CAN identifier and thus defines a range of CAN identifiers that match these bits and may vary in the other bits.
- The txMask of a CanFrameTriggering defines the static bits in a CAN identifier and thus allows to set the other bits using the data appended to the payload.

These parameters are sufficient to support the following scenarios:

- A Pdu is transmitted from one AUTOSAR node to another with variable ID parts. In this case, rxMask and txMask will be identical, and the variable identifier parts placed in the Pdu MetaData by the sender will be routed transparently and received in the same way.
- A Pdu is transmitted by one node with a static identifier and received using the rxMask. In this case, the MetaData is not used, and the receiver is tolerant regarding dynamic address parts.
- J1939 Pdu is sent with fixed priority, but priority is ignored by the receiver. Here, the MetaData may or may not be used, and the rxMask differs from the txMask just in the three priority bits.

15.4 N:1 Sender Receiver communication description in a System Extract over one PhysicalChannel

Description: The System Template supports a System Extract description of a n:1 sender-receiver communication over one PhysicalChannel where each sender and the receiver are located on different Ecus. Each sender Ecu sends the same data marked with a different frame identifier (e.g. CAN Identifier) to the receiver Ecu over the PhysicalChannel.

Implementation: This usage shall be supported by defining one Frame and several FrameTriggerings on the same PhysicalChannel. Each defined FrameTriggering refers to the same Frame. The senders and receivers of a specific FrameTriggering are defined with references to FramePorts.

For every defined Pdu that is contained in the Frame exactly one PduTriggering is defined. This also means that all defined FrameTriggerings refer to the same PduTriggerings with the FrameTriggering.pduTriggering reference.

The communication direction of the Pdu is defined by PduTriggering references to IPduPorts. All sender IPduPorts and receiver IPduPorts are referenced by the same PduTriggering.

The description of ISignals and ISignalTriggerings shall be defined accordingly. Please also note that in case of n:1 sender-receiver communication each sender shall be represented by the same SystemSignal according to [constr_3086].

Example: In figure 15.6 a small example is shown. Three different Ecus (Ecu1, Ecu2, Ecu3) are sending the same Frame to Ecu4.

- Ecu1 sends the Frame with CanId = 3 as described with FrameTriggering3.
- Ecu2 sends the Frame with CanId = 2 as described with FrameTriggering2.
- Ecu3 sends the Frame with CanId = 1 as described with FrameTriggering1.

The Frame contains one single Pdu. Only one PduTriggering is defined here that refers to three IPduPorts with communicationDirection "out" (Ecu1OutPort, Ecu2OutPort and Ecu3OutPort) and to one IPduPort with communicationDirection "in" (Ecu4InPort). Please note that the references between the Triggering elements (FrameTriggering.pduTriggering and PduTriggering.iSignalTriggering) are not visible in figure 15.6 for the sake of clarity.

The description of the ISignal that is included in the Pdu and the ISignalTriggering is defined accordingly.

Upstream Mapping: In the basic Ecu configuration for the receiving Ecu that is derived from such a System Extract all FrameTriggerings shall be mapped to the same Pdu that is passed to a upper layer module (e.g. Nm, PduR). This corresponds to the upstream mapping rules for COM Signals defined in [TPS_SYST_01066] and [TPS_SYST_01067].

- CanIf: several CanIfRxPduCfg containers need to be created with different CanIfRxPduCanIds that all point to the same Pdu (CanIfRxPduRef).
- FrIf: several FrIfFrameTriggering containers need to be created that all point to the same Pdu (FrIfFrameStructure/FrIfPdusInFrame/FrIfPduRef)

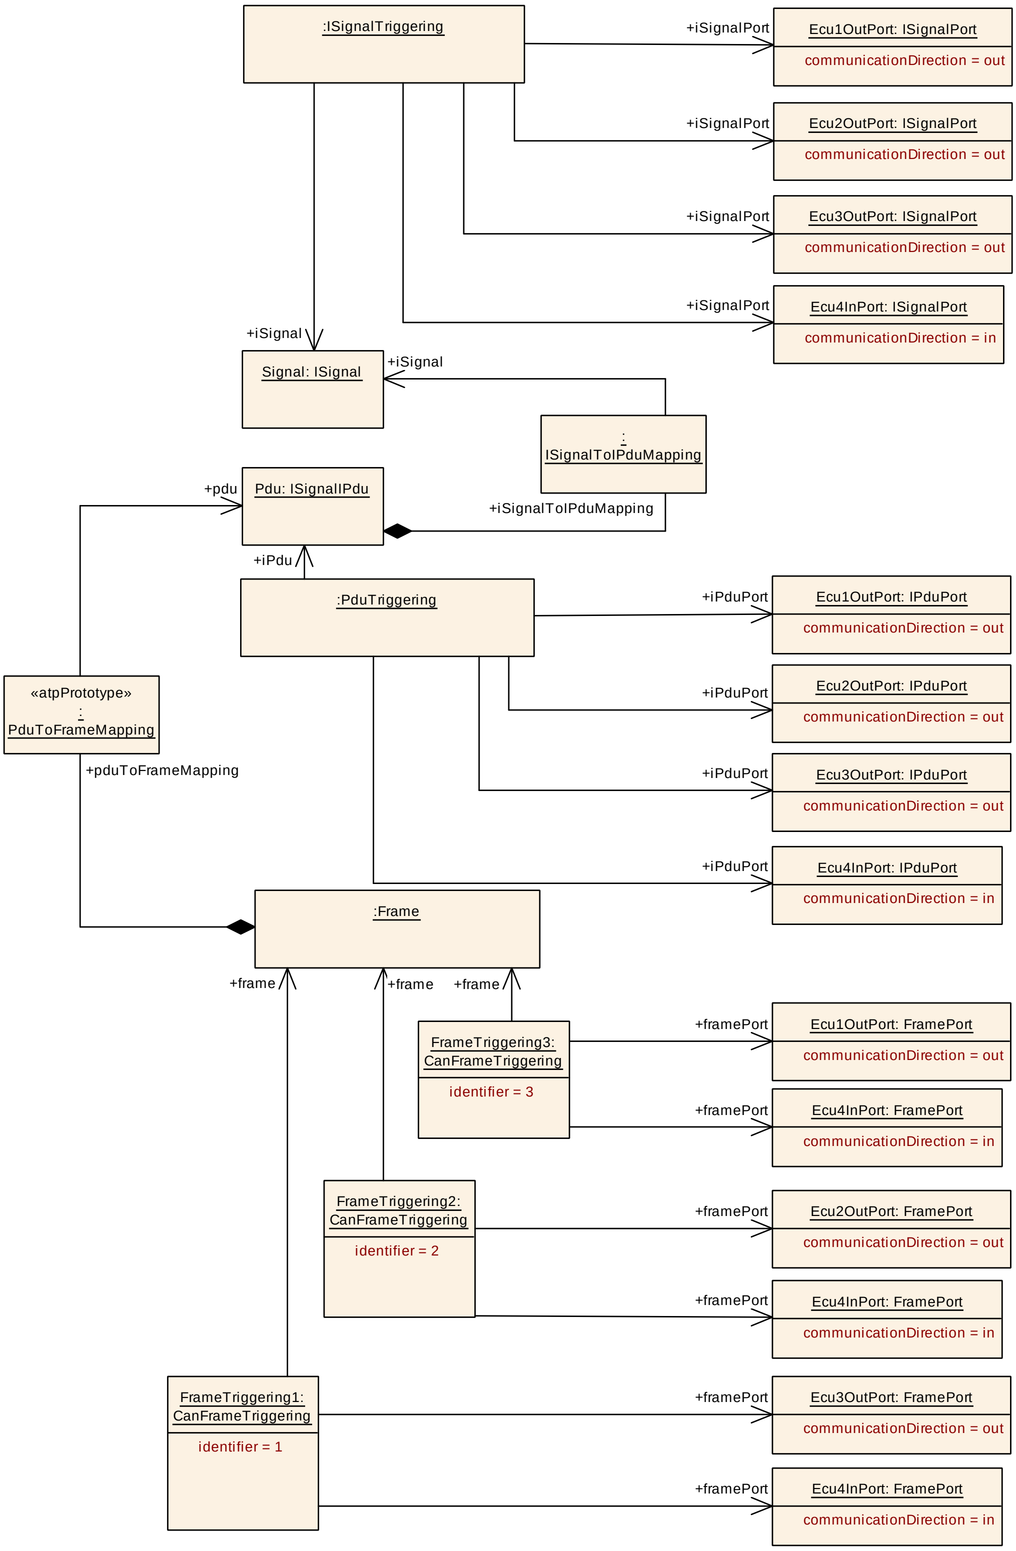

Figure 15.6: Example for a N:1 Sender Receiver communication description in a System Extract

A Reference Material

This chapter contains some relevant reference material for this specification.

A.1 Abbreviations

This section describes abbreviations that are specific to the ECU Configuration Specification and that are not part of the official AUTOSAR Glossary [47].

Following abbreviations are mentioned that are specifically used in this specification:

CAN	Controller Area Network
CAS	Collision Avoidance Symbol
CBV	Control Bit Vector
CC	Communication Controller
CMAC	Cipher-based message authentication code
CSMA/CD	Carrier Sense Multiple Access/Collision Detection
DLC	Data Length Code
DoIp	Diagnostics over IP
DTD	Document Type Definition
ECU	Electrical Control Unit
FIBEX	Field Bus Exchange Format
I^2C	Inter-Integrated Circuit
ICMP	Internet Control Message Protocol
ICV	MACsec Integrity Check Value
ID	Identifier
IP	Internet Protocol
IPDU	Interaction Layer Protocol Data Unit
ISG	Inter-slot Gap
KaY	MACsec Key Agreement Entity
LIN	Local Interconnect Network
LPDU	Data Link Layer Protocol Data Unit
MAC	Message Authentication Code
MAC Address	media access control address
MACsec	Media Access Control security
MOST	Media Oriented Systems Transport
NAD	Node Address for Diagnostic
NID	NOde Identification
NIT	Network Idle Time
NM	Network Management
NPDU	Network Layer Protocol Data Unit
OBD	Onboard Diagnostic
PAE	MACsec Port Access Entity
PDU	Protocol Data Unit
PLCA	Physical Layer Collision Avoidance
POC	Protocol Operation Control
PSK	Pre-shared Key
RSA	Rivest-Shamir-Adleman. A method using public and private key for data encryption and decryption.
RTE	Runtime Environment
SAK	MACsec Secure Association key

SDU	Service Data Unit
SecY	MACsec Security Entity
SID	Service Identifier
SPI	Serial Peripheral Interface
SWC	Software Component
SWC-T	Software Component Template
SYS-T	System Template
TLS	Transport Layer Security
TP	Transport Protocol
TTCAN	Time Triggered Controller Area Network
UML	Unified Modeling Language
VFB	Virtual Functional Bus
XML	Extensible Markup Language
XSD	XML Schema Definition

Table A.1: Abbreviations used in the scope of this Document

A.2 Imposition Times of Constraints

The constraints formulated in this document have different *actual* imposition times which denote the steps in the workflow when the respective constraint has to be imposed.

Some imposition times "include" other imposition times, an example for this relation is discussed in the Table A.2

The imposition times that are considered applicable in the scope of this document[1] are listed in Table A.2.

Please note that the imposition times are intentionally rendered as technical terms such that it is possible to link back from each constraint to the definition of the affected imposition time in Table A.2.

This document has been created to apply primarily for the *AUTOSAR classic platform* and therefore the discussed imposition times also apply exclusively to the *AUTOSAR classic platform*.

Some constraints, however, *may* also be meaningful in the context of other imposition times, applicable for other *AUTOSAR platforms*.

Imposition Time	**Description**	**Motivation**
IT_BinObjMetaData	The definition of binary object meta-data is finished	This imposition time denotes the step in the workflow where the description of CpSoftwareClusterBinaryManifestDescriptor is considered complete so that that the Software Cluster Binary Manifest can be defined during the integration.

▽

[1] Different imposition times may be defined in the context of other AUTOSAR standard documents

△

Imposition Time	Description	Motivation
IT_EcuExt	ECU_EXTRACT is completed	This imposition time denotes the step in the workflow where the ECU_EXTRACT model is considered complete such that it can be used as input for the generation of the RTE.
IT_ResPool	Definition of the resource pool is finished	This imposition time denotes the step in the workflow where the pool of resources which can be provided or required by Software Clusters is considered complete such that such that the development and integration of the Software Cluster can start.
IT_SwCluSysDesc	SW_CLUSTER_SYSTEM_DESCRIPTION is completed	This imposition time denotes the step in the workflow where the SW_CLUSTER_SYSTEM_DESCRIPTION model is considered complete such that the development and integration of the Software Cluster can start.
IT_SysDesc	SYSTEM_DESCRIPTION is completed	This imposition time is aimed at the time when a system description (e.g. SYSTEM_DESCRIPTION or SYSTEM_EXTRACT or ECU_SYSTEM_DESCRIPTION) is complete for exchange between parties and is ready as input for Ecu Extract and Com Stack generators.

Table A.2: Imposition Times of constraints in this document

From the appearance of an imposition time that only applies to the *AUTOSAR classic platform* in the text of a constraint in this document, it **shall not be concluded that the constraint is exclusively applicable to the *AUTOSAR classic platform***.

A.3 Requirements Tracing

The following table references the requirements specified in [48] and links to the fulfillment of these.

Requirement	Description	Satisfied by
[RS_SYST_00001]	Mixed Systems (AUTOSAR/NON-AUTOSAR)	[TPS_SYST_01063] [TPS_SYST_05000]

Table A.3: Requirements Tracing

B Detailed Representation of InstanceRef Associations in the System Template

As a special type of association "instanceRef" refers to an exact instance of the referenced class, requiring additional information of the target and the context. This is explained in detail in the AUTOSAR Generic Structure Template [1]. This chapter contains the detailed InstanceRef Diagrams.

B.1 Usage of InstanceRefs in Data Mapping diagrams

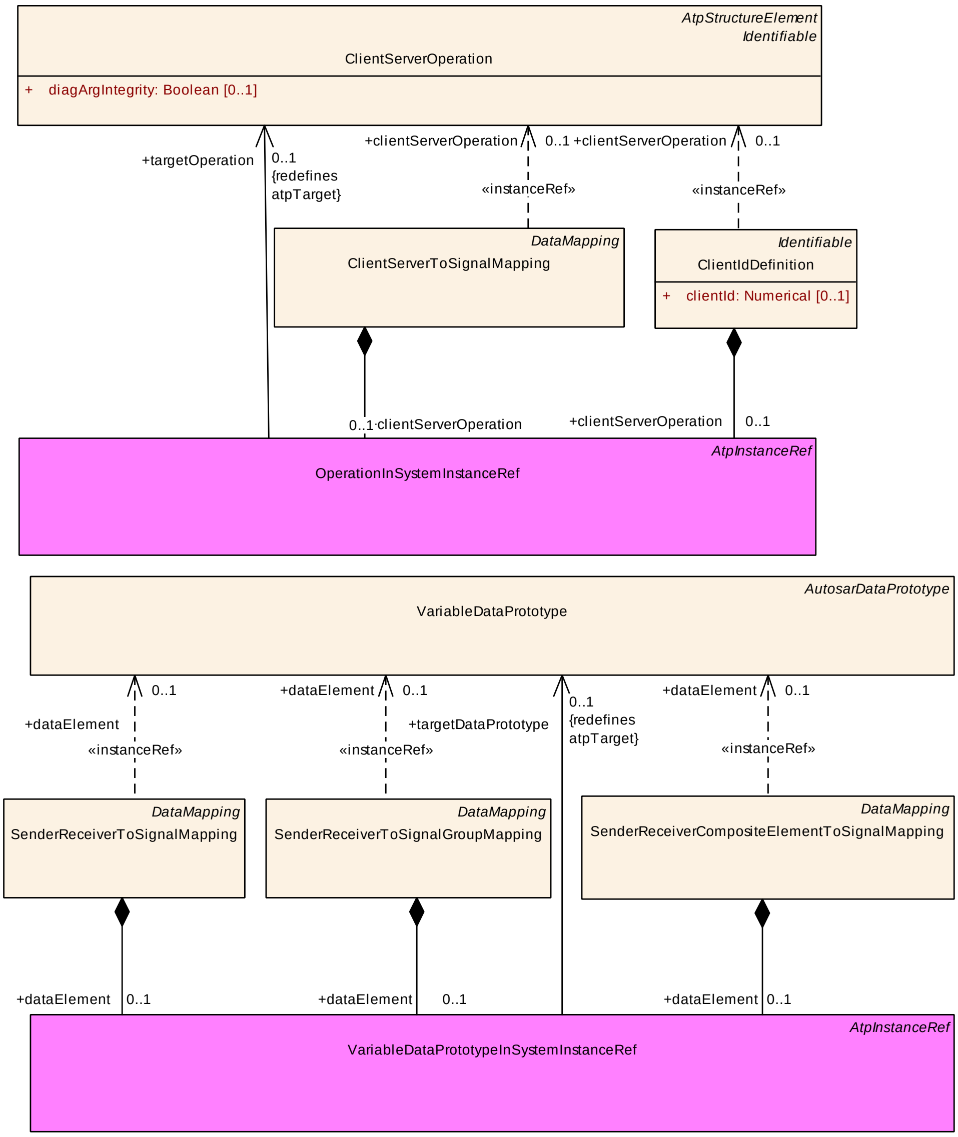

Figure B.1: Data Mapping Instance Ref Usage

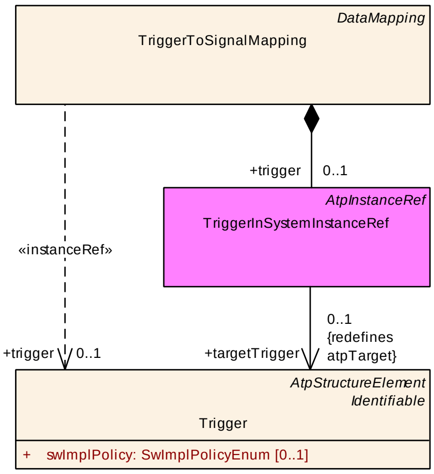

Figure B.2: Modeling of InstanceRef usage for `TriggerInSystemInstanceRef`

B.2 Usage of InstanceRefs in SW Mapping diagrams

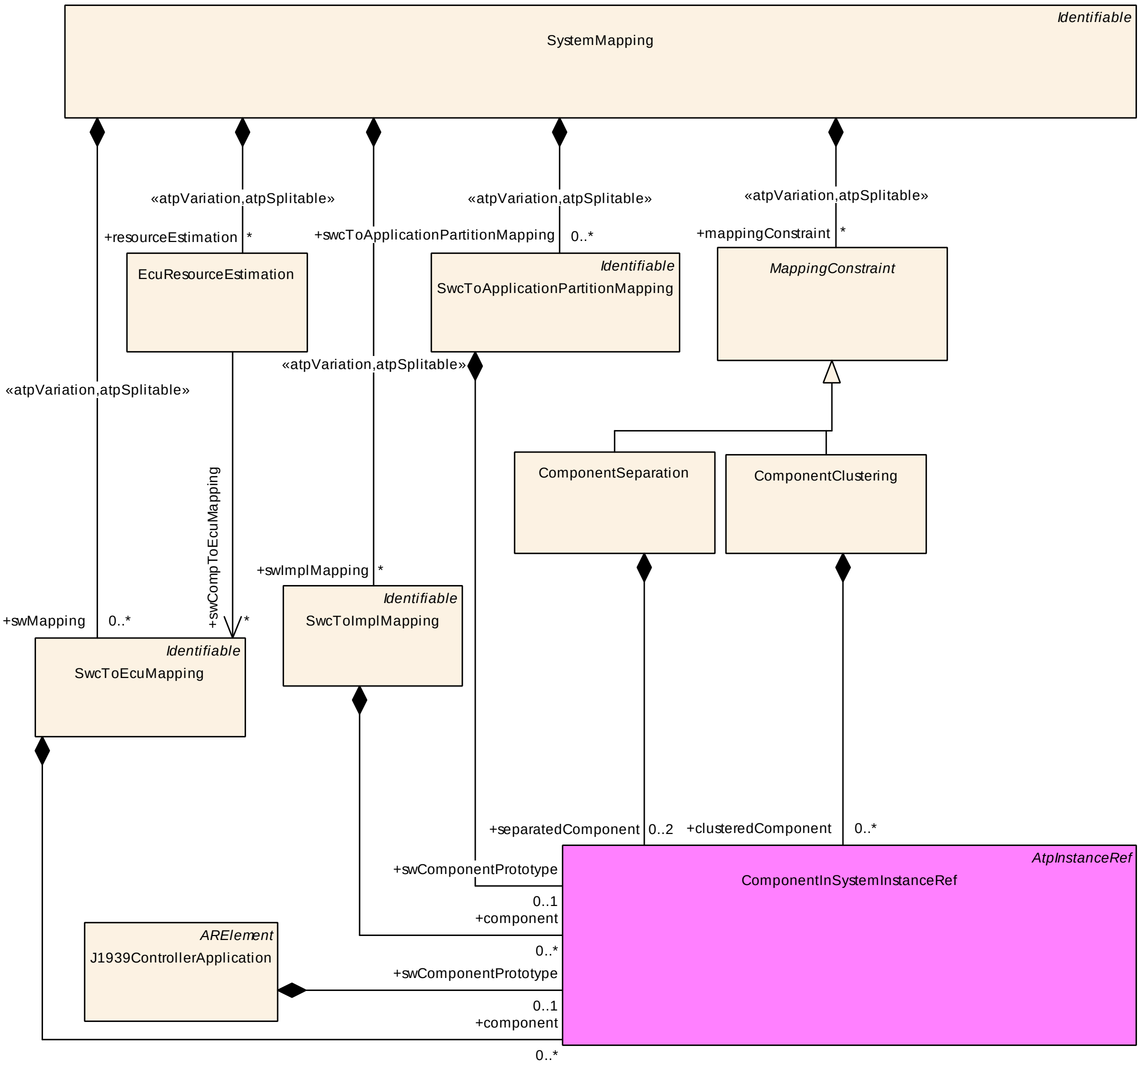

Figure B.3: SW Mapping Instance Ref Usage

△

Class	ComponentInSystemInstanceRef			
context Composition	RootSwComposition Prototype	0..1	ref	**Tags:** xml.sequenceOffset=20
target Component	SwComponent Prototype	1	ref	**Tags:** xml.sequenceOffset=40

Table B.1: ComponentInSystemInstanceRef

If the referenced SwComponentPrototype is located within the RootSwCompositionPrototype of a System then the contextComposition to the RootSwCompositionPrototype shall be provided. In this scenario we have a System Extract where the RootSwComposition may contain other compositions. If the referenced SwComponentPrototype is the RootSwCompositionPrototype itself then contextComposition reference to the RootSwCompositionPrototype shall be skipped and only the targetComponent to the RootSwCompositionPrototype shall be used. In this scenario we have an Ecu Extract where the RootSwComposition contains PortPrototypes that describe the external communication.

B.7 "Operation in System" InstanceRef

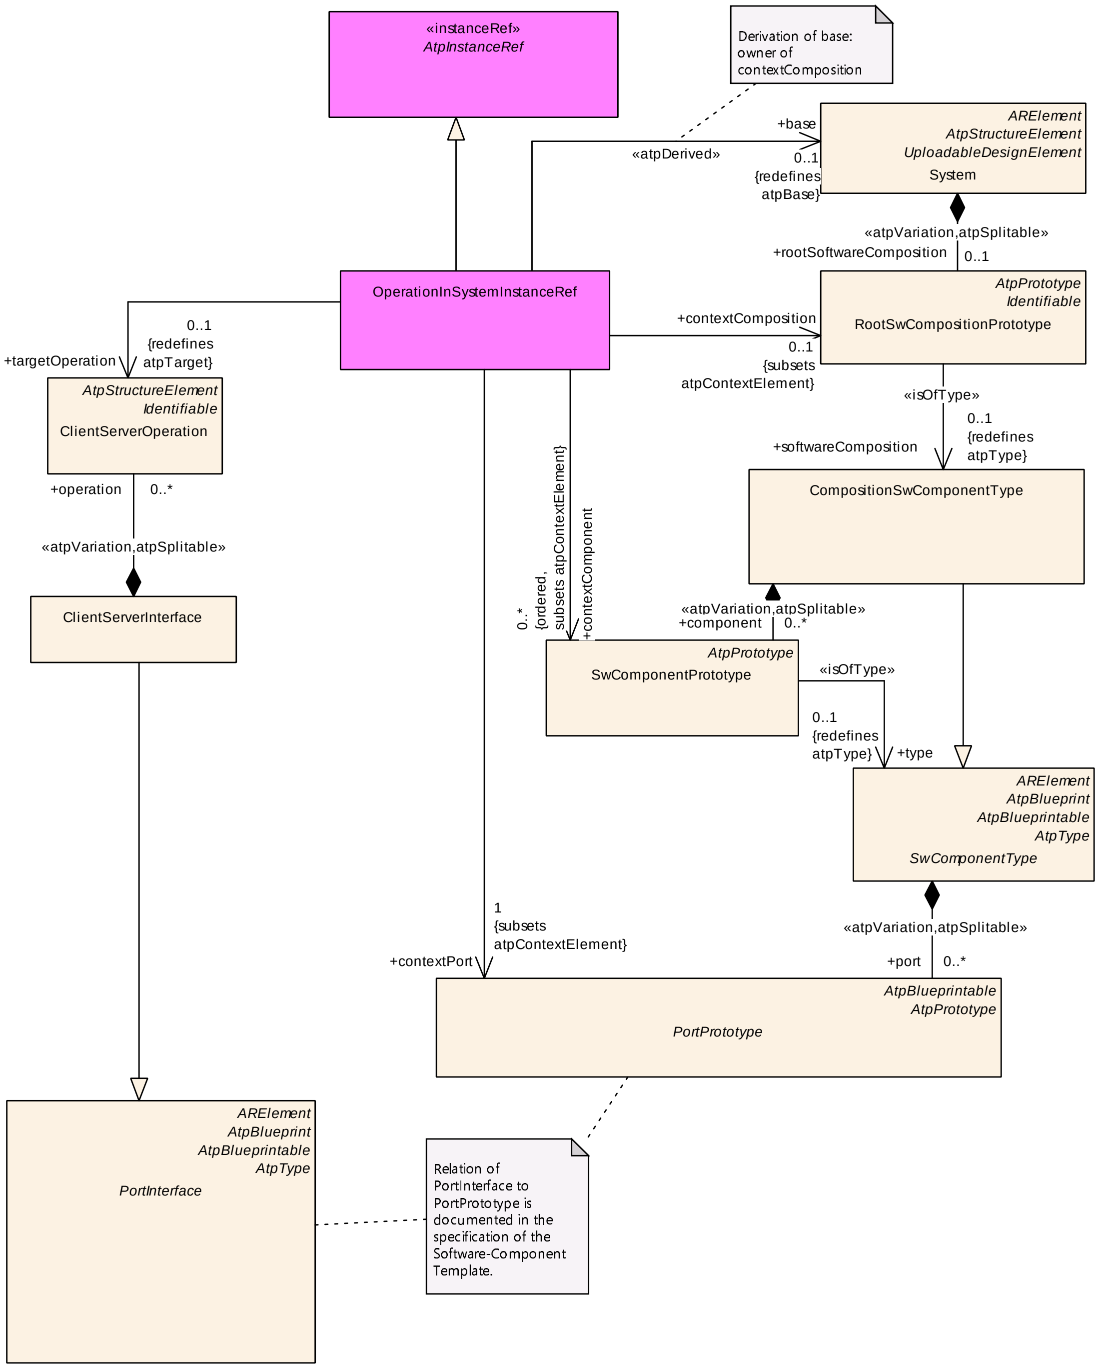

Figure B.8: OperationInSystem InstanceRef

Class	**OperationInSystemInstanceRef**
Package	M2::AUTOSARTemplates::SystemTemplate::InstanceRefs
Note	
Base	*ARObject*, *AtpInstanceRef*

▽

△

Class	OperationInSystemInstanceRef			
Aggregated by	ClientIdDefinition.clientServerOperation, ClientServerToSignalMapping.clientServerOperation, PortElementToCommunicationResourceMapping.clientServerOperation, SwcToSwcOperationArguments.operation			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
base	System	0..1	ref	**Stereotypes:** atpDerived **Tags:** xml.sequenceOffset=10
contextComponent (ordered)	SwComponentPrototype	*	ref	**Tags:** xml.sequenceOffset=30
contextComposition	RootSwCompositionPrototype	0..1	ref	**Tags:** xml.sequenceOffset=20
contextPort	PortPrototype	1	ref	**Tags:** xml.sequenceOffset=40
targetOperation	ClientServerOperation	0..1	ref	**Tags:** xml.sequenceOffset=50

Table B.2: OperationInSystemInstanceRef

If the referenced ClientServerOperation is part of a PortInterface of a SwComponentPrototype that is located within the RootSwCompositionPrototype then the contextComposition reference to the RootSwCompositionPrototype shall be provided. In this scenario we have a System Extract where the RootSwComposition may contain other compositions. If the referenced ClientServerOperation is part of a PortInterface of the RootSwCompositionPrototype itself then the contextComposition reference to the RootSwCompositionPrototype shall be skipped and the RootSwCompositionPrototype shall be referenced as contextComponent. In this scenario we have an Ecu Extract where the RootSwComposition contains PortPrototypes that describe the external communication.

B.8 "VariableDataPrototype" InstanceRef

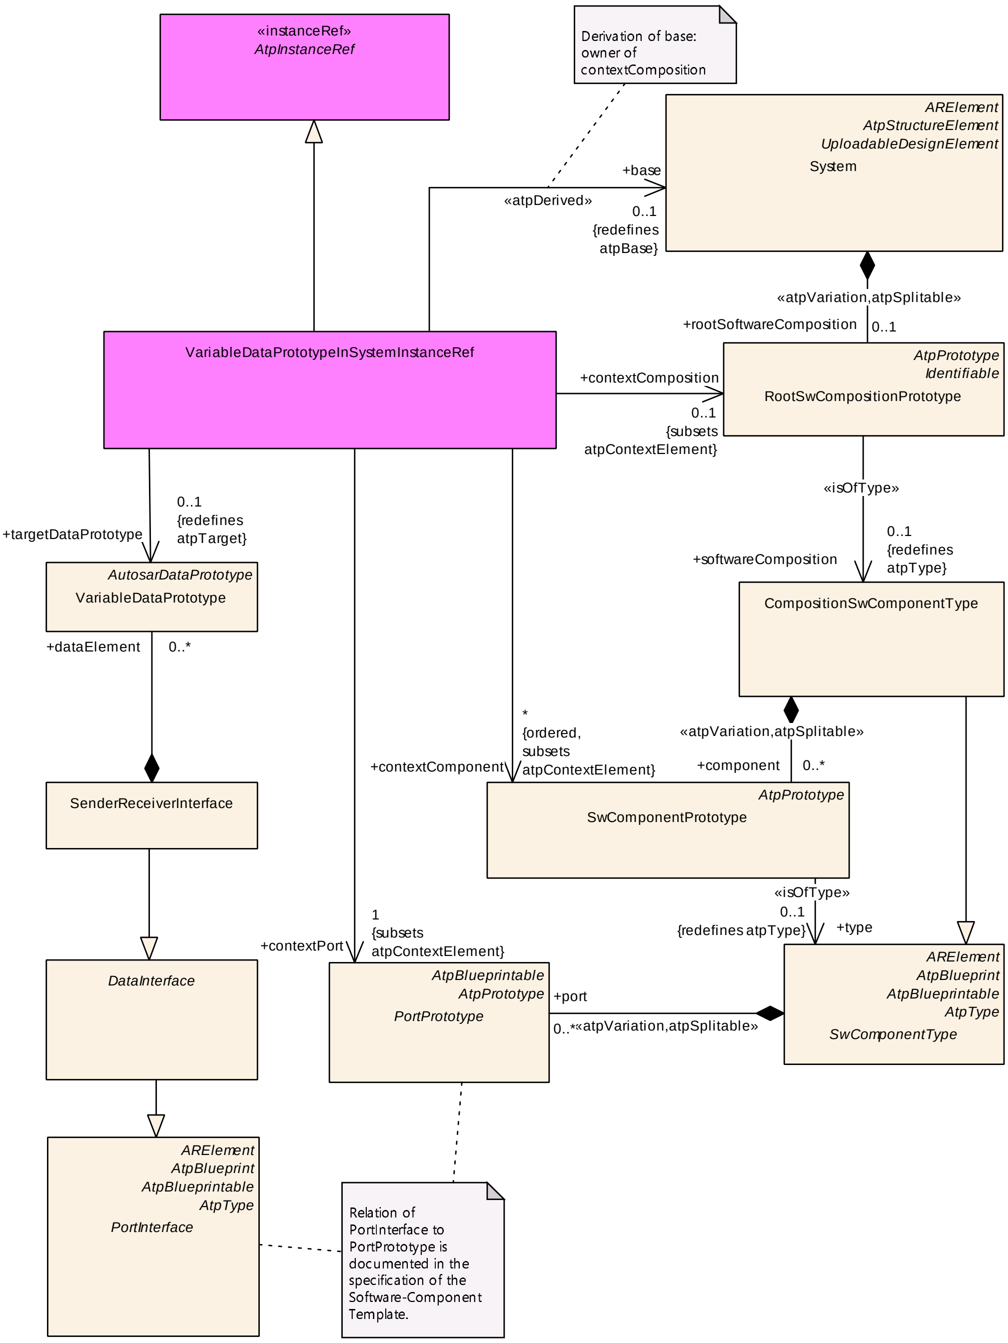

Figure B.9: VariableDataPrototypeInSystem InstanceRef

Class	**VariableDataPrototypeInSystemInstanceRef**
Package	M2::AUTOSARTemplates::SystemTemplate::InstanceRefs
Note	
Base	*ARObject*, *AtpInstanceRef*

△

Class	VariableDataPrototypeInSystemInstanceRef			
Aggregated by	EndToEndProtectionVariablePrototype.receiver, EndToEndProtectionVariablePrototype.sender, PortElementToCommunicationResourceMapping.variableDataPrototype, SenderReceiverCompositeElementToSignalMapping.dataElement, SenderReceiverToSignalGroupMapping.dataElement, SenderReceiverToSignalMapping.dataElement, SignalServiceTranslationEventProps.translationTarget, SwcToSwcSignal.dataElement			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
base	System	0..1	ref	**Stereotypes:** atpDerived
contextComponent (ordered)	SwComponentPrototype	*	ref	
contextComposition	RootSwCompositionPrototype	0..1	ref	
contextPort	PortPrototype	1	ref	
targetDataPrototype	VariableDataPrototype	0..1	ref	

Table B.3: VariableDataPrototypeInSystemInstanceRef

If the referenced VariableDataPrototype is part of a PortInterface of a SwComponentPrototype that is located within the RootSwCompositionPrototype then the contextComposition reference to the RootSwCompositionPrototype shall be provided. In this scenario we have a System Extract where the RootSwComposition may contain other compositions. If the referenced VariableDataPrototype is part of a PortInterface of the RootSwCompositionPrototype itself then the contextComposition reference to the RootSwCompositionPrototype shall be skipped and the RootSwCompositionPrototype shall be referenced as contextComponent. In this scenario we have an Ecu Extract where the RootSwComposition contains PortPrototypes that describe the external communication.

Please note that the xml.sequenceOffset is not set for this InstanceRef and therefore the properties are serialized in an alphabetical order.

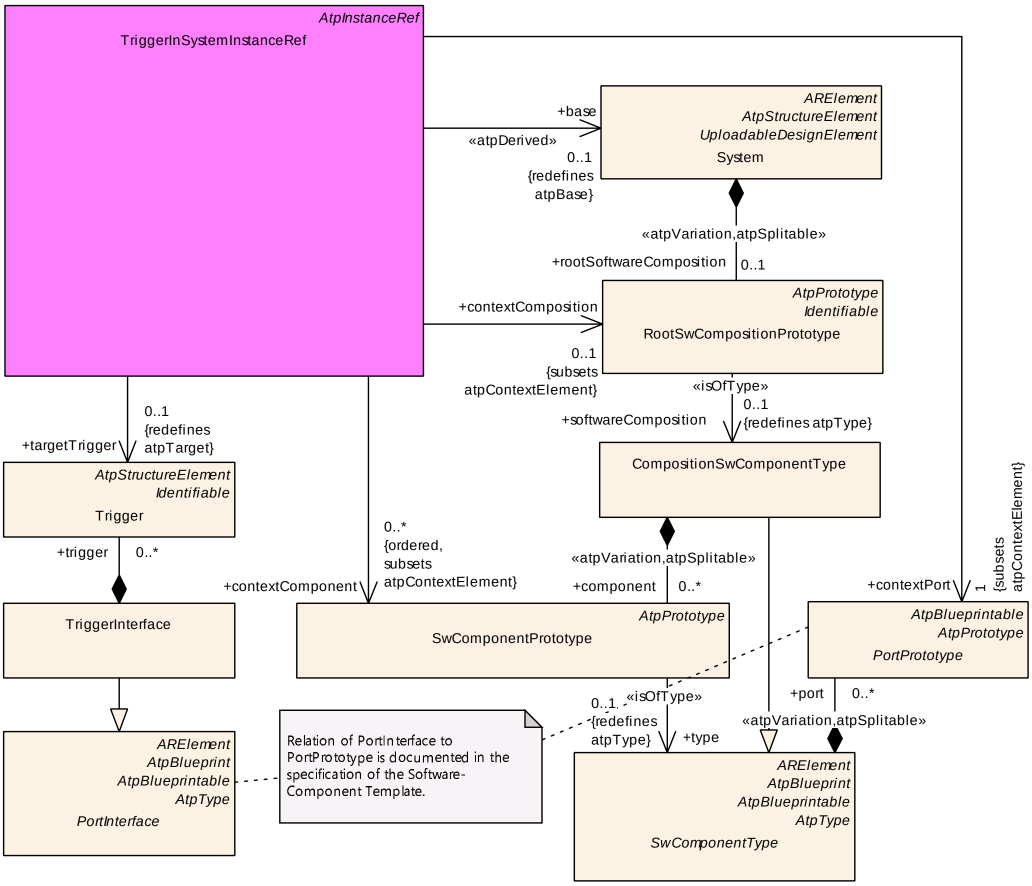

Figure B.10: TriggerInSystemInstanceRef

Class	TriggerInSystemInstanceRef			
Package	M2::AUTOSARTemplates::SystemTemplate::InstanceRefs			
Note				
Base	*ARObject*, *AtpInstanceRef*			
Aggregated by	PortElementToCommunicationResourceMapping.trigger, TriggerToSignalMapping.trigger			
Attribute	**Type**	**Mult.**	**Kind**	**Note**
base	System	0..1	ref	This represents that base of the InstanceRef **Stereotypes:** atpDerived **Tags:** xml.sequenceOffset=10
context Component (ordered)	SwComponent Prototype	*	ref	This represents the set of context components. The association is ordered because it needs to respect the nesting order. **Tags:** xml.sequenceOffset=30
context Composition	RootSwComposition Prototype	0..1	ref	This represents the reference to the RootSw Compositiontype representing a context of the Instance Ref. **Tags:** xml.sequenceOffset=20
contextPort	PortPrototype	1	ref	This represents the PortPrototype in which the target Trigger is located. **Tags:** xml.sequenceOffset=40
targetTrigger	Trigger	0..1	ref	This represents the target Trigger. **Tags:** xml.sequenceOffset=50

Table B.4: TriggerInSystemInstanceRef

If the referenced Trigger is part of a PortInterface of a SwComponentPrototype that is located within the RootSwCompositionPrototype then the base reference and the contextComposition reference to the RootSwCompositionPrototype shall be provided. If the referenced Trigger is part of a PortInterface of the RootSwCompositionPrototype itself then the base reference and the contextComposition reference to the RootSwCompositionPrototype shall be skipped and the RootSwCompositionPrototype shall be referenced as contextComponent.

B.9 "PortGroup in System" InstanceRef

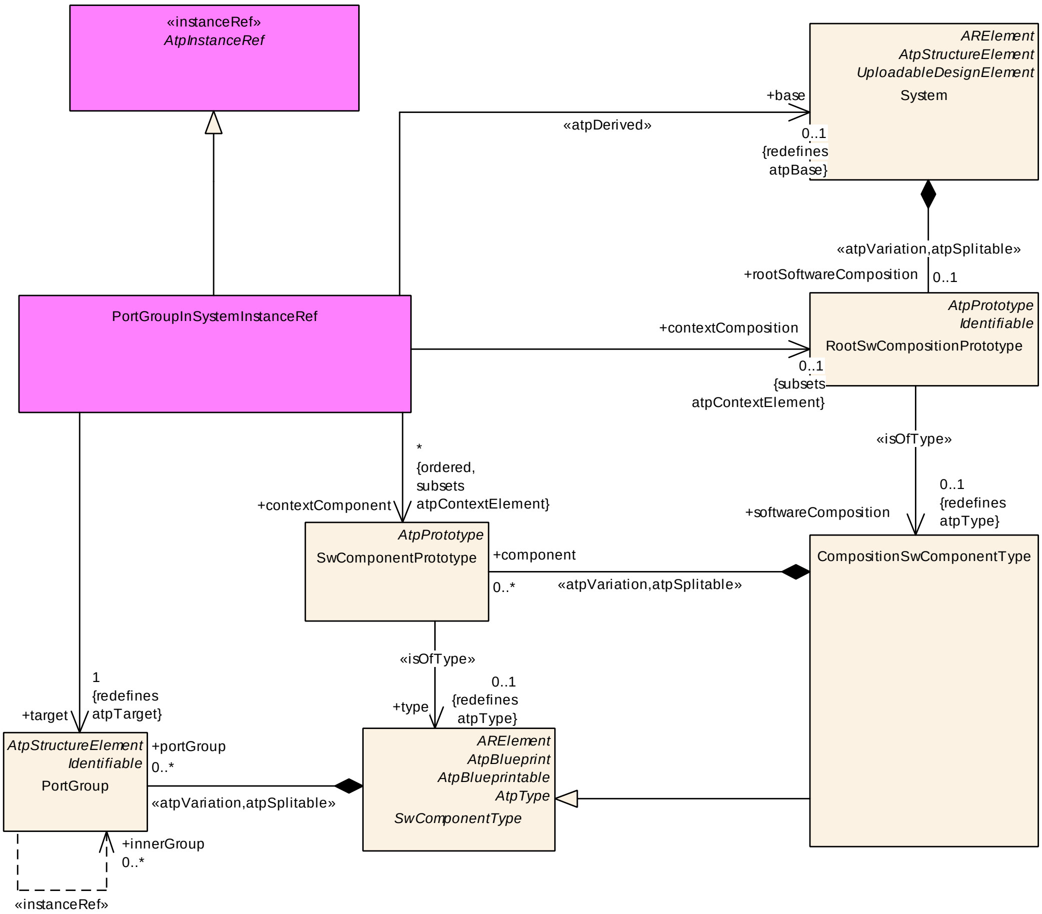

Figure B.11: PortGroupInSystem InstanceRef

Class	**PortGroupInSystemInstanceRef**			
Package	M2::AUTOSARTemplates::SystemTemplate::InstanceRefs			
Note				
Base	*ARObject*, *AtpInstanceRef*			
Aggregated by	ComManagementMapping.comManagementPortGroup, PncMapping.vfc			
Attribute	*Type*	*Mult.*	*Kind*	*Note*
base	System	0..1	ref	**Stereotypes:** atpDerived **Tags:** xml.sequenceOffset=10
context Component (ordered)	SwComponent Prototype	*	ref	**Tags:** xml.sequenceOffset=30
context Composition	RootSwComposition Prototype	0..1	ref	**Tags:** xml.sequenceOffset=20
target	PortGroup	1	ref	Link to a PortGroup that is defined in a component which is part of this CompositionSwComponentType. **Tags:** xml.sequenceOffset=40

Table B.5: PortGroupInSystemInstanceRef

If the referenced PortGroup is part of a SwComponentPrototype that is located within the RootSwCompositionPrototype then the contextComposition reference to the RootSwCompositionPrototype shall be provided. In this scenario we have a System Extract where the RootSwComposition may contain other compositions. If the referenced PortGroup is part of the RootSwCompositionPrototype itself then the contextComposition reference to the RootSwCompositionPrototype shall be skipped and the RootSwCompositionPrototype shall be referenced as contextComponent. In this scenario we have an Ecu Extract where the RootSwComposition contains PortPrototypes that describe the external communication.

B.10 "DataPrototype in PortInterface" InstanceRef

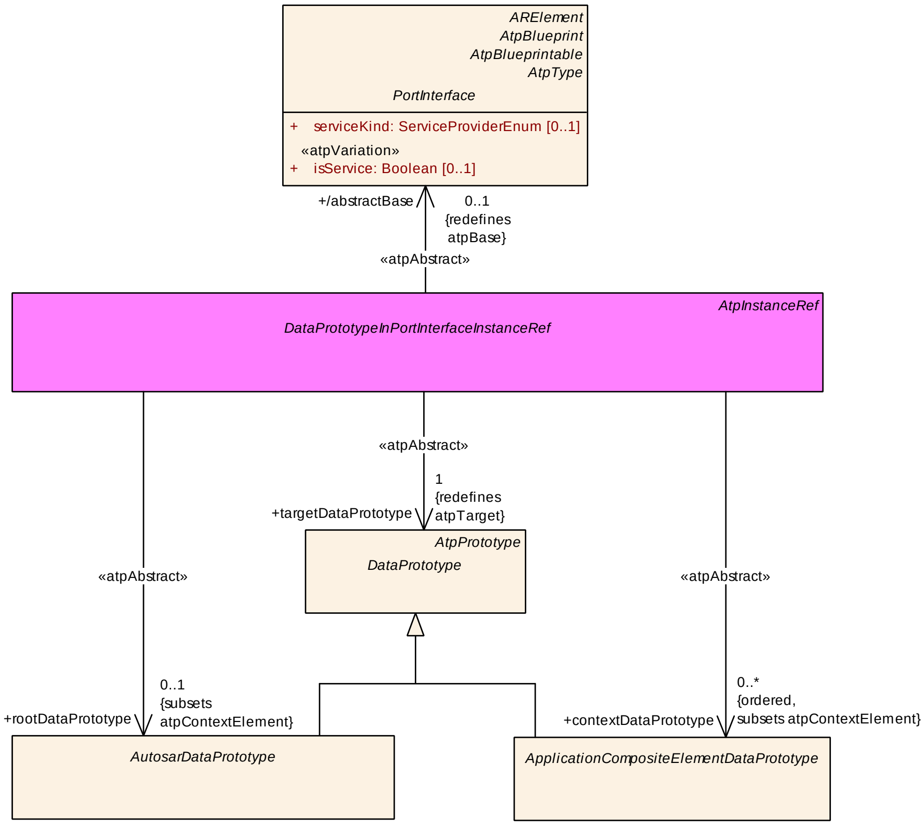

Figure B.12: DataPrototypeInPortInterfaceInstanceRef InstanceRef

Class	***DataPrototypeInPortInterfaceInstanceRef*** (abstract)			
Package	M2::AUTOSARTemplates::SystemTemplate::Transformer::InstanceRef			
Note	This meta-class represents the ability to: • refer to a DataPrototype in the context of a PortInterface. • refer to the internal structure of a DataPrototype which is typed by an ApplicationDatatype in the context of a PortInterface.			
Base	*ARObject*, *AtpInstanceRef*			
Subclasses	DataPrototypeInClientServerInterfaceInstanceRef, DataPrototypeInSenderReceiverInterfaceInstanceRef			
Attribute	***Type***	***Mult.***	***Kind***	***Note***
abstractBase	PortInterface	0..1	ref	**Stereotypes:** atpAbstract
contextData Prototype (ordered)	ApplicationComposite ElementDataPrototype	*	ref	**Stereotypes:** atpAbstract **Tags:** xml.sequenceOffset=20
rootData Prototype	AutosarDataPrototype	0..1	ref	**Stereotypes:** atpAbstract **Tags:** xml.sequenceOffset=10
targetData Prototype	DataPrototype	1	ref	**Stereotypes:** atpAbstract **Tags:** xml.sequenceOffset=30

Table B.6: DataPrototypeInPortInterfaceInstanceRef

If the referenced target `DataPrototype` is the root `AutosarDataPrototype` in a `PortInterface` then only the `targetDataPrototype` reference shall be provided.

If the referenced DataPrototype is part of a root AutosarDataPrototype that is part of a PortInterface then the rootDataPrototype shall be provided. The referenced ApplicationCompositeElementDataPrototype can be arbitrarily nested within a DataPrototype. In such a case additional contextDataPrototype references shall be provided.

Please note that the specializations DataPrototypeInSenderReceiverInterfaceInstanceRef and DataPrototypeInClientServerInterfaceInstanceRef work in the same way.

C Harmonization between Upstream Templates and ECU Configuration

This chapter describes the mapping of the ECU Configuration parameters (M1 model) onto the meta-classes and attributes of the AUTOSAR upstream templates (System Template, SW Component Template and ECU Resource Template).

The relationships between upstream templates and ECU Configuration are described in order to answer typical questions like:

- How shall a supplier use the information in a System Description in order to fulfill the needs defined by the systems engineer?
- How is a tool vendor supposed to generate an ECU Configuration Description out of ECU Extract of System Description?

In addition to adhering to the mapping rules defined in this appendix an automated generation of an ECU Configuration Description out of ECU Extract of System Description should apply a certain implementation-specific name mangling when deriving the shortName of the EcucContainerValue elements to ensure that the resulting ECU Configuration Description is valid with respect to constr_2508 of [1].

Please note that the tables contain the following columns:

bsw module: Name of BSW module

bsw context: Reference to parameter container

bsw type: Type of parameter

bsw param: Name of the BSW parameter

bsw desc: Description from the configuration document

m2 template: System Template, SW Component Template, ECU Resource Template

m2 param: Name of the upstream template parameter

m2 description: Description from the upstream template definition

mapping rule: Textual description on how to transform between M2 and BSW domains

mapping type:

- local: no mapping needed since parameter local to BSW
- partial: some data can be automatically mapped but not all
- full: all data can be automatically mapped

C.1 Can

BSW Module	BSW Context	
Can	Can/CanConfigSet/CanController/CanControllerBaudrateConfig	
BSW Parameter		**BSW Type**
CanControllerBaudRate		ECUC-FLOAT-PARAM-DEF
BSW Description		
Specifies the baudrate of the controller in kbps.		
Template Description		
Channels speed in bits/s.		
M2 Parameter		
SystemTemplate::Fibex::FibexCore::CoreTopology::CommunicationCluster.baudrate		
Mapping Rule		**Mapping Type**
SystemTemplate speed is in bps, so divide it by 1000 to get kbps		full
Mapping Status		**ECUC Parameter ID**
valid		[ECUC_Can_00005]

BSW Module	BSW Context	
Can	Can/CanConfigSet/CanController/CanControllerBaudrateConfig/CanControllerFdBaudrateConfig	
BSW Parameter		**BSW Type**
CanControllerFdBaudRate		ECUC-FLOAT-PARAM-DEF
BSW Description		
Specifies the data segment baud rate of the controller in kbps.		
Template Description		
Specifies the data segment baud rate of the controller in bits/s.		
M2 Parameter		
SystemTemplate::Fibex::Fibex4Can::CanTopology::AbstractCanCluster.canFdBaudrate		
Mapping Rule		**Mapping Type**
SystemTemplate speed is in bps, so divide it by 1000 to get kbps		full
Mapping Status		**ECUC Parameter ID**
valid		[ECUC_Can_00481]

BSW Module	BSW Context	
Can	Can/CanConfigSet/CanController/CanControllerBaudrateConfig/CanControllerFdBaudrateConfig	
BSW Parameter		**BSW Type**
CanControllerPropSeg		ECUC-INTEGER-PARAM-DEF
BSW Description		
Specifies propagation delay in time quantas.		
Template Description		
Specifies propagation delay in time quantas.		
M2 Parameter		
SystemTemplate::Fibex::Fibex4Can::CanTopology::CanControllerFdConfiguration.propSeg		
Mapping Rule		**Mapping Type**
1:1 mapping		full
Mapping Status		**ECUC Parameter ID**
valid		[ECUC_Can_00476]

<tr><td colspan="4">Specifies the Transmitter Delay Compensation Offset in minimum time quanta (see [17]). Transmitter Delay Compensation Offset is used to adjust the position of the Secondary Sample Point (SSP), relative to the beginning of the received bit. If this parameter is configured, the Transmitter Delay Compensation is done by measurement of the CAN controller. If not specified, Transmitter Delay Compensation is disabled.

Note: MTQ == Minimum Time Quanta in seconds == 1/(frequency of the CAN controller clock) Secondary Sample Point Offset in seconds = CanControllerSspOffset * MTQ

Example: CAN controller clock frequency = 20MHz => MTQ = 1/20 * 10ˆ(-6) s = 0,05 us = 50ns Baud rate = 1MBit/s => Bit Time = 1/(1 * 10ˆ6) s/Bit = 1 * 10ˆ(-6) = 1us/Bit SSP = 75% => SSP in seconds = 0,75 * 1us = 750 ns CanControllerSspOffset in MTQ = 750ns / 50ns = 15

Note: Please consider the minimum range (0..63) stated in [17] and the range definition (0..127) used as per [19].</td></tr>
<tr><th colspan="4">Template Description</th></tr>

BSW Module	**BSW Context**	
Can	Can/CanConfigSet/CanHardwareObject	
BSW Parameter		**BSW Type**
CanFdPaddingValue		ECUC-INTEGER-PARAM-DEF
BSW Description		
Specifies the value which is used to pad unspecified data in CAN FD frames > 8 bytes for transmission. This is necessary due to the discrete possible values of the DLC if > 8 bytes. If the length of a PDU which was requested to be sent does not match the allowed DLC values, the remaining bytes up to the next possible value shall be padded with this value.		
Template Description		
CanControllerFdConfiguration.paddingValue: Specifies the value which is used to pad unused data in CAN FD frames which are bigger than 8 byte if the length of a Pdu which was requested to be sent does not match the allowed DLC values of CAN FD. **CanControllerFdConfigurationRequirements.paddingValue:** Specifies the value which is used to pad unused data in CAN FD frames which are bigger than 8 byte if the length of a Pdu which was requested to be sent does not match the allowed DLC values of CAN FD.

CanIf	CanIf/CanIfInitCfg/CanIfRxPduCfg/CanIfRxPduCanIdType		
BSW Parameter		**BSW Type**	
EXTENDED_CAN		ECUC-ENUMERATION-LITERAL-DEF	
BSW Description			
CAN 2.0 or CAN FD frame with extended identifier (29 bits)			
Template Description			
CanFrameTriggering.canAddressingMode: The CAN protocol supports two types of frame formats. The standard frame format uses 11-bit identifiers and is defined in the CAN specification 2.0 A. Additionally the extended frame format allows 29-bit identifiers and is defined in the CAN specification 2.0 B. **CanFrameTriggering.canFrameRxBehavior:** Defines which CAN protocol shall be expected for frame reception.			
M2 Parameter			
SystemTemplate::Fibex::Fibex4Can::CanCommunication::CanFrameTriggering.canAddressingMode, SystemTemplate::Fibex::Fibex4Can::CanCommunication::CanFrameTriggering.canFrameRxBehavior			
Mapping Rule			**Mapping Type**
canAddressingMode = "extended" and canFrameRxBehavior = "any".			full
Mapping Status			**ECUC Parameter ID**
valid
