Advice for users

AUTOSAR specifications may contain exemplary items (exemplary reference models, "use cases", and/or references to exemplary technical solutions, devices, processes or software).

Any such exemplary items are contained in the specifications for illustration purposes only, and they themselves are not part of the AUTOSAR Standard. Neither their presence in such specifications, nor any later documentation of AUTOSAR conformance of products actually implementing such exemplary items, imply that intellectual property rights covering such exemplary items are licensed under the same rules as applicable to the AUTOSAR Standard.

1 Introduction and overview

This protocol specification specifies the format, message sequences and semantics of the AUTOSAR Protocol "Scalable service-Oriented Middleware over IP (SOME/IP)".

SOME/IP is an automotive/embedded communication protocol which supports remote procedure calls, event notifications and the underlying serialization/wire format. The only valid abbreviation is SOME/IP. Other abbreviations (e.g. Some/IP) are wrong and shall not be used.

1.1 Protocol purpose and objectives

The basic motivation to specify "Yet another RPC-Mechanism" instead of using an existing infrastructure/technology is the goal to have a technology that:

- Fulfills the hard requirements regarding resource consumption in an embedded world
- Is compatible through as many use-cases and communication partners as possible
- compatible with AUTOSAR at least on the wire-format level; i.e. can communicate with PDUs AUTOSAR can receive and send without modification to the AUTOSAR standard. The mappings within AUTOSAR shall be chosen according to the SOME/IP specification.
- Provides the features required by automotive use-cases
- Is scalable from tiny to large platforms

1.2 Applicability of the protocol

SOME/IP shall be implemented on different operating systems (i.e. AUTOSAR, GENIVI, and OSEK) and even embedded devices without operating system. SOME/IP shall be used for inter-ECU Client/Server Serialization. An implementation of SOME/IP allows AUTOSAR to parse the RPC PDUs and transport the signals to the application.

1.2.1 Constraints and assumptions

This document specifies the SOME/IP protocol on network level. It was created during elaboration of the AUTOSAR Foundation Standard 1.0.0 which took place in parallel to the development of the AUTOSAR Classic Standard 4.3.0. It already reflects all changes implied to SOME/IP by the work which was done for AUTOSAR Classic
Therefore the SOME/IP protocol specified here is not fully backward-compatible to the SOME/IP protocol used in AUTOSAR Classic Standard 4.2.2. The most important differences are:

- Unicode strings are always preceded by a BOM (see Chapter 4.1.4.3) The older version was not consistent with respect to the usage of BOMs. The current version of SOME/IP mandates that every unicode string starts with a BOM. Everything else is no string but an array of uint8, uint16 or uint32 elements.

- Message Types have been changed (see [PRS_SOMEIP_00055] and Table 4.4): The types for acknowledgements (REQUEST_ACK, REQUEST_NO_RETURN_ACK, NOTIFICATION_ACK, RESPONSE_ACK and ERROR_ACK) were completely removed because they were defined but never used in the protocol.

- Segmentation functionality (SOME/IP-TP) was introduced (see Chapter 4.2.1.4): Large data (>1400 Bytes) can now be transferred via UDP. SOME/IP-TP can segment larger data into small chunks which can be transferred via UDP and reassembled at receiver side.

1.2.2 Limitations

This document gives a holistic overview over SOME/IP but doesn’t state any requirements towards any implementation of BSW modules.

Please be aware that not all parts of SOME/IP may be implemented in AUTOSAR.

1.3 Dependencies

There are no dependencies to AUTOSAR SWS modules.

1.4 Document Structure

The SOME/IP PRS will describe the following two aspects of SOME/IP.

Specification of SOME/IP on wire-format (Serialization)

- Structure of Header Format
- How the different data types are serialized as per SOME/IP

Specification of Protocol for Event and RPC-based communication

- Transport Protocol
• Rules that govern the RPC for SOME/IP
## 2 Protocol Requirements

### 2.1 Requirements Traceability

<tr>
<td>Union</td>
<td>A data structure that dynamically assumes different data types.</td>
</tr>
</tbody>
</table>

Table 3.1: Acronyms and Abbreviations
4 Protocol specification

SOME/IP provides service oriented communication over a network. It is based on service definitions that list the functionality that the service provides. A service can consist of combinations of zero or multiple events, methods and fields.

Events provide data that are sent cyclically or on change from the provider to the subscriber.

Methods provide the possibility to the subscriber to issue remote procedure calls which are executed on provider side.

Fields are combinations of one or more of the following three
- a notifier which sends data on change from the provider to the subscribers
- a getter which can be called by the subscriber to explicitly query the provider for the value
- a setter which can be called by the subscriber when it wants to change the value on provider side

The major difference between the notifier of a field and an event is that events are only sent on change, the notifier of a field additionally sends the data directly after subscription.

4.1 Specification of SOME/IP on wire-format (Serialization)

Serialization describes the way data is represented in protocol data units (PDUs) as payload of either UDP or TCP messages, transported over an IP-based automotive in-vehicle network.

4.1.1 Header

[PRS_SOMEIP_00030]
The structure of header layout is as shown in the Figure 4.1.

![Figure 4.1: SOME/IP Header Format](image)

**4.1.1.1 Message ID [32 Bit]**

**[PRS_SOMEIP_00034]** The Message ID shall be a 32 Bit identifier that is used to identify the RPC call to a method of an application or to identify an event.

**[PRS_SOMEIP_00035]** The assignment of the Message ID shall be up to the user. However, the Message ID shall be unique for the whole system (i.e., the vehicle). The Message ID is similar to a CAN ID and should be handled via a comparable process.

**[PRS_SOMEIP_00038]** Message IDs of method calls shall be structured in the ID with $2^{16}$ services with $2^{15}$ methods as shown in Table 4.1

<table>
<thead>
<tr>
<th>Service ID [16 Bit]</th>
<th>0 [1 Bit]</th>
<th>Method ID [last 15 Bit]</th>
</tr>
</thead>
</table>

**Table 4.1: Structure of ID**

**4.1.1.2 Length [32 Bit]**

**[PRS_SOMEIP_00042]** Length field shall contain the length in Byte starting from Request ID/Client ID until the end of the SOME/IP message.
4.1.1.3 Request ID [32 Bit]

The Request ID allows a provider and subscriber to differentiate multiple parallel uses of the same method, event, getter or setter.

[PRS_SOMEIP_00043] The Request ID shall be unique for a provider- and subscriber-combination (i.e. one subscription) only. (RS_SOMEIP_00027)

[PRS_SOMEIP_00704] When generating a response message, the provider shall copy the Request ID from the request to the response message. (RS_SOMEIP_00027) Note: This allows the subscriber to map a response to the issued request even with more than one request outstanding.

[PRS_SOMEIP_00044] Request IDs must not be reused until the response is arrived or is not expected to arrive anymore (timeout). (RS_SOMEIP_00027)

4.1.1.3.1 Structure of the Request ID

[PRS_SOMEIP_00046] In AUTOSAR the Request ID shall be constructed of the Client ID and Session ID as shown in Table 4.2 (RS_SOMEIP_00027)

<table>
<thead>
<tr>
<th>Client ID [16 Bits]</th>
<th>Session ID [16 Bits]</th>
</tr>
</thead>
</table>

Table 4.2: Structure of Request ID

Note:
This means that the implementer of an ECU can define the Client-IDs as required by his implementation and the provider does not need to know this layout or definitions because he just copies the complete Request-ID in the response.

[PRS_SOMEIP_00702] The Client ID is the unique identifier for the calling client inside the ECU. The Client ID allows an ECU to differentiate calls from multiple clients to the same method. (RS_SOMEIP_00027)

[PRS_SOMEIP_00703] The Session ID is a unique identifier chosen by the subscribers for each call. The Session ID allows a subscriber to differentiate multiple calls to the same method. (RS_SOMEIP_00027)

[PRS_SOMEIP_00532] The Client ID shall also support being unique in the overall vehicle by having a configurable prefix or fixed value (e.g. the most significant byte of Client ID being the diagnostics address or a configured Client ID for a given application/SW-C). ()

For example:

| Client ID Prefix [8 Bits] | Client ID [8 Bits] | Session ID [16 Bits] |
Table 4.3: Example of Client ID

[PRS_SOMEIP_00533] [Request/Response methods shall use session handling with Session IDs. Session ID should be incremented after each call.] (RS_SOMEIP_00027)

[PRS_SOMEIP_00521] [When the Session ID reaches 0xFFFF, it shall wrap around and start again.] (RS_SOMEIP_00027)

[PRS_SOMEIP_00739] [A subscriber has to ignore a response if the session id of a response does not equal the session id of request.] (RS_SOMEIP_00027)

4.1.1.4 Protocol Version [8 Bit]

[PRS_SOMEIP_00052] [Protocol Version shall be an 8 Bit field containing the SOME/IP protocol version.] (RS_SOMEIP_00027)

4.1.1.5 Interface Version [8 Bit]

[PRS_SOMEIP_00053] [Interface Version shall be an 8 Bit field that contains the Major Version of the Service Interface.] (RS_SOMEIP_00027)

4.1.1.6 Message Type [8 Bit]

[PRS_SOMEIP_00055] [The Message Type field is used to differentiate different types of messages and shall contain the following values as shown in Table 4.4] (RS_SOMEIP_00027)

<table>
<thead>
<tr>
<th>Number</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>REQUEST</td>
<td>A request expecting a response (even void)</td>
</tr>
<tr>
<td>0x01</td>
<td>REQUEST_NO_RETURN</td>
<td>A fire&amp;forget request</td>
</tr>
<tr>
<td>0x02</td>
<td>NOTIFICATION</td>
<td>A request of a notification/event callback expecting no response</td>
</tr>
<tr>
<td>0x80</td>
<td>RESPONSE</td>
<td>The response message</td>
</tr>
<tr>
<td>0x81</td>
<td>ERROR</td>
<td>The response containing an error</td>
</tr>
<tr>
<td>0x20</td>
<td>TP_REQUEST</td>
<td>A TP request expecting a response (even void)</td>
</tr>
<tr>
<td>0x21</td>
<td>TP_REQUEST_NO_RETURN</td>
<td>A TP fire&amp;forget request</td>
</tr>
<tr>
<td>0x22</td>
<td>TP_NOTIFICATION</td>
<td>A TP request of a notification/event callback expecting no response</td>
</tr>
<tr>
<td>0x23</td>
<td>TP_RESPONSE</td>
<td>The TP response message</td>
</tr>
<tr>
<td>0x24</td>
<td>TP_ERROR</td>
<td>The TP response containing an error</td>
</tr>
</tbody>
</table>
Table 4.4: Message Types

**[PRS_SOMEIP_00701]** Regular request (message type 0x00) shall be answered by a response (message type 0x80), when no error occurred. If errors occur an error message (message type 0x81) shall be sent. *(RS_SOMEIP_00027)*

It is also possible to send a request that does not have a response message (message type 0x01). For updating values through notification a callback interface exists (message type 0x02).

**[PRS_SOMEIP_00367]** The 3rd highest bit of the Message Type (=0x20) shall be called TP-Flag and shall be set to 1 to signal that the current SOME/IP message is a segment. The other bits of the Message Type are set as specified in this Section. *(RS_SOMEIP_00027, RS_SOMEIP_00051)*

**Note:** Segments of the Message Type Request (0x00) have the Message Type (0x20), segments of the Message Type Response (0x80) have the Message Type (0xa0), and so on. For details see (Chapter 4.2.1.4)

### 4.1.1.7 Return Code [8 Bit]

**[PRS_SOMEIP_00058]** The Return Code shall be used to signal whether a request was successfully processed. For simplification of the header layout, every message transports the field Return Code. The allowed Return Codes for specific message types are shown in Table 4.5 *(RS_SOMEIP_00027)*

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Allowed Return Codes</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQUEST</td>
<td>N/A set to 0x00 (E_OK)</td>
</tr>
<tr>
<td>REQUEST_NO_RETURN</td>
<td>N/A set to 0x00 (E_OK)</td>
</tr>
<tr>
<td>NOTIFICATION</td>
<td>N/A set to 0x00 (E_OK)</td>
</tr>
<tr>
<td>RESPONSE</td>
<td>See Return Codes in [PRS_SOMEIP_00191]</td>
</tr>
<tr>
<td>ERROR</td>
<td>See Return Codes in [PRS_SOMEIP_00191]. Shall not be 0x00 (E_OK).</td>
</tr>
</tbody>
</table>

**Table 4.5: Allowed Return Codes for specific Message Types**

### 4.1.1.8 Payload [variable size]

In the payload field the parameters are carried. The serialization of the parameters will be specified in the following section.

The size of the SOME/IP payload field depends on the transport protocol used. With UDP the SOME/IP payload shall be between 0 and 1400 Bytes. The limitation to 1400 Bytes is needed in order to allow for future changes to protocol stack (e.g. changing to...
IPv6 or adding security means). Since TCP supports segmentation of payloads, larger sizes are automatically supported.

Payload might consists of data elements for events or parameters for methods.

### 4.1.2 Event, Field and Eventgroup

Eventgroup is a logical grouping of events and notification events of fields inside a service in order to allow subscription.

[PRS_SOMEIP_00040] Events and notifications are transported using RPC, Events shall be structured as shown in Table 4.6

(RS_SOMEIP_00027)

| Service ID [16 Bit] | 1 [1 Bit] | Event ID [last 15 Bit] |

Table 4.6: Structure of Event ID

[PRS_SOMEIP_00365] Empty eventgroups shall not be used.

(RS_SOMEIP_00027)

[PRS_SOMEIP_00366] Events as well as fields are mapped to at least one event-group.

(RS_SOMEIP_00027)

### 4.1.3 Endianess

[PRS_SOMEIP_00368] SOME/IP Header shall be encoded in network byte order (big endian).

(RS_SOMEIP_00026)

[PRS_SOMEIP_00369] The byte order of the parameters inside the payload shall be defined by configuration.

(RS_SOMEIP_00026)

### 4.1.4 Serialization of Data Structures

The serialization is based on the parameter list defined by the interface specification. The interface specification defines the exact position of all data structures in the PDU and has to consider the memory alignment.

Alignment is used to align the beginning of data by inserting padding elements after the data in order to ensure that the aligned data starts at certain memory addresses.

There are processor architectures which can access data more efficiently (i.e. master) when they start at addresses which are multiples of a certain number (e.g multiples of 32 Bit).
Alignment of data shall be realized by inserting padding elements between the preceding data and the data that shall be aligned. (RS_SOMEIP_0028)

Alignment shall always be calculated from start of SOME/IP message. (RS_SOMEIP_0028)

There shall be no padding behind fixed length data elements to ensure alignment of the following data. (RS_SOMEIP_0028)

Note:
If data behind fixed length data elements shall be padded, this has to be explicitly considered in the data type definition.

The serialization shall not try to automatically align data structures but shall be aligned as specified in the interface specification. (RS_SOMEIP_0028)

The alignment of data behind variable length data elements shall be a multiple of 8, 16 or 32 Bits. (RS_SOMEIP_0028)

4.1.4.1 Basic Datatypes

The following basic datatypes as shown in Table 4.7 shall be supported:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Size [bit]</th>
<th>Remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>TRUE/FALSE value</td>
<td>8</td>
<td>FALSE (0), TRUE (1)</td>
</tr>
<tr>
<td>uint8</td>
<td>unsigned Integer</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>uint16</td>
<td>unsigned Integer</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>uint32</td>
<td>unsigned Integer</td>
<td>32</td>
<td></td>
</tr>
<tr>
<td>sint8</td>
<td>signed Integer</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>sint16</td>
<td>signed Integer</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>sint32</td>
<td>signed Integer</td>
<td>32</td>
<td></td>
</tr>
<tr>
<td>float32</td>
<td>floating point number</td>
<td>32</td>
<td>IEEE 754 binary32 (Single Precision)</td>
</tr>
<tr>
<td>float64</td>
<td>floating point number</td>
<td>64</td>
<td>IEEE 754 binary64 (Double Precision)</td>
</tr>
</tbody>
</table>

Table 4.7: Supported basic Data Types

The Byte Order is specified for each parameter by configuration.

For the evaluation of a Boolean value only the lowest bit of the uint8 is interpreted and the rest is ignored. (RS_SOMEIP_0028, RS_SOMEIP_0030, RS_SOMEIP_0031, RS_SOMEIP_0032)
4.1.4.2 Structured Datatypes (structs)

The serialization of a struct shall be close to the in-memory layout. This means, only the parameters shall be serialized sequentially into the buffer. Especially for structs it is important to consider the correct memory alignment.

Example:

```
Struct_1
  uint32 a
  float32 b[2]
Struct_2 c
Struct_2
  uint32 d
  float32 e[2]
Struct_3 f
```

```
serialization
  uint32 a
  float32 b_1
  float32 b_2
  uint32 d
  float32 e_1
  float32 e_2
  ...
```

Figure 4.2: Serialization of Structs

[PRS_SOMEIP_00077] The SOME/IP implementation shall not automatically insert dummy/padding data. (RS_SOMEIP_00033)

[PRS_SOMEIP_00079] An optional length field of 8, 16 or 32 Bit may be inserted in front of the Struct depending on the configuration. (RS_SOMEIP_00033)

[PRS_SOMEIP_00370] The length field of the struct shall describe the number of bytes this struct occupies for SOME/IP transport. (RS_SOMEIP_00033)

[PRS_SOMEIP_00371] If the length is greater than the length of the struct as specified in the data type definition only the bytes specified in the data type shall be interpreted and the other bytes shall be skipped based on the length field. (RS_SOMEIP_00033)

[PRS_SOMEIP_00900] If the length is less than the sum of the lengths of all struct members and no substitution for the missing data can be provided locally by the receiver, the deserialization shall be aborted and the message shall be treated as malformed. (RS_SOMEIP_00033)

[PRS_SOMEIP_00712] The serialization of structs shall follow the depth-first-traversal of the structured data type. (RS_SOMEIP_00033)
4.1.4.3 Strings

Following requirements are common for both fixed length and dynamic length strings.

[PRS_SOMEIP_00372] Different Unicode encoding shall be supported including UTF-8, UTF-16BE and UTF-16LE. (RS_SOMEIP_00038)

[PRS_SOMEIP_00084] UTF-16 and UTF-16BE strings shall be zero terminated with a "\0" character. This means they shall end with (at least) two 0x00 Bytes. (RS_SOMEIP_00038)

[PRS_SOMEIP_00085] UTF-16LE and UTF-16BE strings shall have an even length. (RS_SOMEIP_00038)

[PRS_SOMEIP_00086] UTF-16LE and UTF-16BE strings having an odd length the last byte shall be ignored. The two bytes before shall be 0x00 bytes (termination). (RS_SOMEIP_00038)

[PRS_SOMEIP_00087] All strings shall always start with a Byte Order Mark (BOM). The BOM shall be included in fixed-length-strings as well as dynamic-length strings. BOM allows the possibility to detect the used encoding. (RS_SOMEIP_00038)

4.1.4.3.1 Strings (fixed length)

[PRS_SOMEIP_00373] Strings shall be terminated with a "\0"-character despite having a fixed length. (RS_SOMEIP_00038)

[PRS_SOMEIP_00374] The length of the string (this includes the "\0") in bytes has to be specified in the data type definition. Fill unused space using "\0". BOM is included in the length. (RS_SOMEIP_00038)

[PRS_SOMEIP_00911] If the length of a string with fixed length is greater than expected (expectation shall be based on the data type definition), the deserialization shall be aborted and the message shall be treated as malformed. (RS_SOMEIP_00038)

[PRS_SOMEIP_00912] If the length of a string with fixed length is less than expected (expectation shall be based on the data type definition) and it is correctly terminated using "\0", it shall be accepted. (RS_SOMEIP_00038)

[PRS_SOMEIP_00913] If the length of a string with fixed length is less than expected (expectation shall be based on the data type definition) and it is not correctly terminated using "\0", the deserialization shall be aborted and the message shall be treated as malformed. (RS_SOMEIP_00038)

4.1.4.3.2 Strings (dynamic length)

[PRS_SOMEIP_00089] Strings with dynamic length shall start with a length field. The length is measured in bytes. (RS_SOMEIP_00039)
The length field is placed before the BOM, and the BOM is included in the length. (RS_SOMEIP_00039)

String are terminated with a "\0". (RS_SOMEIP_00039)

Note:
The maximum number of bytes of the string (including termination with "\0") shall also be derived from the data type definition.

[PRS_SOMEIP_00084], [PRS_SOMEIP_00085] and [PRS_SOMEIP_00086] shall also be valid for strings with dynamic length. (RS_SOMEIP_00039)

Dynamic length strings shall have a length field of 8, 16 or 32 Bit. This length is defined by the Interface Specification. (RS_SOMEIP_00039)

If not specified otherwise in the interface specification the length of the length field is 32 Bit (default length of length field). (RS_SOMEIP_00039)

The length of the Strings length field is not considered in the value of the length field; i.e. the length field does not count itself. (RS_SOMEIP_00039)

Dynamic length strings shall have a length field of 8, 16 or 32 Bit. This length is defined by the Interface Specification. (RS_SOMEIP_00039)

If the length of an fixed length array is greater than expected (expectation shall be based on the data type definition) only the elements specified in the data type shall be interpreted and the other bytes shall be skipped based on the length field. (RS_SOMEIP_00036)

If the length of a string with variable length is greater than expected (expectation shall be based on the data type definition), the deserialization shall be aborted and the message shall be treated as malformed. (RS_SOMEIP_00038)

Instead of transferring application strings as SOME/IP strings with BOM and "\0" termination, strings can also be transported as plain dynamic length arrays without BOM and "\0" termination (see chapter 4.1.4.5). Please note that this requires the full string handling (e.g. endianness conversion) to be done in the applications.

4.1.4.4 Arrays (fixed length)

The length of fixed length arrays is defined by the data type definition. They can be seen as repeated elements. In chapter 4.1.4.5 dynamic length arrays are shown, which can be also used. Fixed length arrays are easier for use in very small devices. Dynamic length arrays might need more resources on the ECU using them.

If the length of an fixed length array is greater than expected (expectation shall be based on the data type definition) only the elements specified in the data type shall be interpreted and the other bytes shall be skipped based on the length field. (RS_SOMEIP_00036)

If the length of a fixed length array is less than expected (expectation shall be based on the data type definition) and no substitution for the missing data can be provided locally by the receiver, the deserialization shall be aborted and the message shall be treated as malformed. (RS_SOMEIP_00036)
4.1.4.4.1 One-dimensional

[PRS_SOMEIP_00099]

The one-dimensional arrays with fixed length "n" shall carry exactly "n" elements of the same type. The layout is shown in Figure 4.3. (RS_SOMEIP_00035, RS_SOMEIP_00036)

![Figure 4.3: One-dimensional array (fixed length)]

4.1.4.4.2 Multidimensional

[PRS_SOMEIP_00101]

The serialization of multidimensional arrays follows the in-memory layout of multidimensional arrays in the programming language (row-major order) and is shown in Figure 4.4. (RS_SOMEIP_00035, RS_SOMEIP_00036)

![Figure 4.4: Multidimensional array (fixed length)]
4.1.4.5 Dynamic Length Arrays

[PRS_SOMEIP_00375] The layout of arrays with dynamic length shall be based on the layout of fixed length arrays. *(RS_SOMEIP_00037)*

[PRS_SOMEIP_00376] An optional length field at the beginning of an array should be used to specify the length of the array in Bytes. *(RS_SOMEIP_00037)*

[PRS_SOMEIP_00107] The length field shall have a length of 0, 8, 16 or 32 Bits. This shall be determined by configuration. *(RS_SOMEIP_00037)*

[PRS_SOMEIP_00377] The length does not include the size of the length field. *(RS_SOMEIP_00037)*

Note:
If the length of the length field is set to 0 Bits, the number of elements in the array has to be fixed; thus, being an array with fixed length.

The layout of dynamic arrays is shown in Figure 4.5 and Figure 4.6.

![Figure 4.5: One-dimensional array (dynamic length)](image)

In the one-dimensional array one length field is used, which carries the number of bytes used for the array.

The number of static length elements can be easily calculated by dividing by the size of an element.

In the case of dynamical length elements the number of elements cannot be calculated, but the elements must be parsed sequentially.

Figure 4.6 shows the structure of a Multidimensional Array of dynamic length.
If static buffer size allocation is required, the data type definition shall define the maximum length of each dimension.

Rationale: When measuring the length in Bytes, complex multi-dimensional arrays can be skipped over in deserialization.

SOME/IP also supports that different length for columns and different length for rows in the same dimension. See $k_1$ and $k_2$ in Figure 4.6. A length indicator needs to be present in front of every dynamic length array. This applies for both outer and all inner/nested arrays.

If the length of an variable length array is greater than expected (expectation shall be based on the data type definition) only the elements specified in the data type shall be interpreted and the other bytes shall be skipped based on the length field.

4.1.4.6 Enumeration

Enumerations are not considered in SOME/IP. Enumerations shall be transmitted as unsigned integer datatypes.

4.1.4.7 Bitfield

Bitfields shall be transported as unsigned datatypes uint8/uint16/uint32.
4.1.4.8 Union / Variant

There are use cases for defining data as unions on the network where the payload can be of different data types.

A union (also called variant) is such a parameter that can contain different types of data. For example, if one defines a union of type uint8 and type uint16, the union shall carry data which are a uint8 or a uint16.

Which data type will be transmitted in the payload can only be decided during execution. In this case, however, it is necessary to not only send the data itself but add an information about the applicable data type as a form of "meta-data" to the transmission.

By the means of the attached meta-data the sender can identify the applicable data type of the union and the receiver can accordingly access the data properly.

[PRS_SOMEIP_00118] A union shall be used to transport data with alternative data types over the network. (RS_SOMEIP_00034)

[PRS_SOMEIP_00119] A union shall consist of a length field, type selector and the payload as shown in Table 4.8: (RS_SOMEIP_00034)

<table>
<thead>
<tr>
<th>Length field [32 bit]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type field [32 bit]</td>
</tr>
<tr>
<td>Data including padding [sizeof(padding) = length - sizeof(data)]</td>
</tr>
</tbody>
</table>

Table 4.8: Default Serialization of Unions

[PRS_SOMEIP_00126] The length field shall define the size of the data and padding in bytes and does not include the size of the length field and type field. (RS_SOMEIP_00034)

Note:
The padding can be used to align following data in the serialized data stream if configured accordingly.

[PRS_SOMEIP_00121] The length of the length field shall be defined by configuration and shall be 32, 16, 8, or 0 bits. (RS_SOMEIP_00034)

[PRS_SOMEIP_00122] A length of the length field of 0 Bit means that no length field will be written to the PDU. (RS_SOMEIP_00034)

[PRS_SOMEIP_00123] If the length of the length field is 0 Bit, all types in the union shall be of the same length. (RS_SOMEIP_00034)

[PRS_SOMEIP_00129] The type field shall specify the data type of the data. (RS_SOMEIP_00034)

[PRS_SOMEIP_00127] The length of the type field shall be defined by configuration and shall be 32, 16, or 8 bits. (RS_SOMEIP_00034)
Possible values of the type field shall be defined by the configuration for each union separately.  

The value 0 of the type field shall be reserved for the NULL type.

Note:
This denotes an empty union.

Whether NULL is allowed for a union or not shall be defined by configuration.

The payload is serialized depending on the type in the type field.

In the following example a length of the length field is specified as 32 Bits. The union shall support a uint8 and a uint16 as data. Both are padded to the 32 bit boundary (length=4 Bytes).

A uint8 will be serialized like shown in Table 4.9.

<table>
<thead>
<tr>
<th>Length</th>
<th>Type</th>
<th>Data</th>
<th>Padding</th>
<th>Padding</th>
<th>Padding</th>
<th>Padding</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 Bytes</td>
<td>1</td>
<td>uint8</td>
<td>0x00</td>
<td>0x00</td>
<td>0x00</td>
<td>0x00</td>
</tr>
</tbody>
</table>

Table 4.9: Example: uint8

A uint16 will be serialized like shown in Table 4.10.

<table>
<thead>
<tr>
<th>Length</th>
<th>Type</th>
<th>Data</th>
<th>Padding</th>
<th>Padding</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 Bytes</td>
<td>2</td>
<td>uint16</td>
<td>0x00</td>
<td>0x00</td>
</tr>
</tbody>
</table>

Table 4.10: Example: uint16

If the length of a union is greater than expected (expectation shall be based on the data type definition) only the bytes specified in the data type shall be interpreted and the other bytes shall be skipped based on the length field.

If the length of a union is less than expected (expectation shall be based on the data type definition) it shall depend on the inner data type whether valid data can be deserialized or the deserialization shall be aborted and the message shall be treated as malformed.

4.2 Specification of SOME/IP Protocol

This chapter describes the Remote Procedure Call (RPC), Event Notifications and Error Handling of SOME/IP.
4.2.1 Transport Protocol Bindings

In order to transport SOME/IP messages different transport protocols may be used. SOME/IP currently supports UDP and TCP. Their bindings are explained in the following sections, while Chapter 6 discusses which transport protocol to choose.

[PRS_SOMEIP_00138] If a server runs different instances of the same service, messages belonging to different service instances shall be mapped to the service instance by the transport protocol port on the server side. For details see Chapter 4.2.1.3 (RS_SOMEIP_00010)

[PRS_SOMEIP_00535] All Transport Protocol Bindings shall support transporting more than one SOME/IP message in a Transport Layer PDU (i.e. UDP packet or TCP segment). (RS_SOMEIP_00010)

[PRS_SOMEIP_00142] The receiving SOME/IP implementation shall be capable of receiving unaligned SOME/IP messages transported by UDP or TCP. (RS_SOMEIP_00010)

Rationale:
When transporting multiple SOME/IP payloads in UDP or TCP the alignment of the payloads can be only guaranteed, if the length of every payloads is a multiple of the alignment size (e.g. 32 bits).

4.2.1.1 UDP Binding

[PRS_SOMEIP_00139] The UDP binding of SOME/IP shall be achieved by transporting SOME/IP messages in UDP packets. (RS_SOMEIP_00010)

[PRS_SOMEIP_00137] SOME/IP protocol shall not restrict the usage of UPD fragmentation. (RS_SOMEIP_00010)

[PRS_SOMEIP_00140] The header format allows transporting more than one SOME/IP message in a single UDP packet. The SOME/IP implementation shall identify the end of a SOME/IP message by means of the SOME/IP length field. Based on the UDP length field, SOME/IP shall determine if there are additional SOME/IP messages in the UDP packet. (RS_SOMEIP_00010)

[PRS_SOMEIP_00141] Each SOME/IP payload shall have its own SOME/IP header. (RS_SOMEIP_00010)

4.2.1.2 TCP Binding

The TCP binding of SOME/IP is heavily based on the UDP binding. In contrast to the UDP binding, the TCP binding allows much bigger SOME/IP messages and uses the robustness features of TCP (coping with loss, reorder, duplication, etc.).
In order to lower latency and reaction time, Nagle’s algorithm should be turned off (TCP_NODELAY).

[PRS_SOMEIP_00706] [When the TCP connection is lost, outstanding requests shall be handled as timeouts. ] (RS_SOMEIP_00010) Since TCP handles reliability, additional means of reliability are not needed.

[PRS_SOMEIP_00707] [The client and server shall use a single TCP connection for all methods, events, and notifications of a service instance. When having more than one instance of a service a TCP connection per services instance is needed.] (RS_SOMEIP_00010)

[PRS_SOMEIP_00708] [The TCP connection shall be opened by the client, when the first method call shall be transported or the client tries to receive the first notifications.] (RS_SOMEIP_00010)

The client is responsible for reestablishing the TCP connection whenever it fails.

[PRS_SOMEIP_00709] [The TCP connection shall be closed by the client, when the TCP connection is not required anymore.] (RS_SOMEIP_00010)

[PRS_SOMEIP_00710] [The TCP connection shall be closed by the client, when all Services using the TCP connections are not available anymore (stopped or timed out).] (RS_SOMEIP_00010)

[PRS_SOMEIP_00711] [The server shall not stop the TCP connection when stopping all services. Give the client enough time to process the control data to shutdown the TCP connection itself.] (RS_SOMEIP_00010)

Rational:
When the server closes the TCP connection before the client recognized that the TCP is not needed anymore, the client will try to reestablish the TCP connection.

### 4.2.1.2.1 Allowing resync to TCP stream using Magic Cookies

[PRS_SOMEIP_00154] [In order to allow testing tools to identify the boundaries of SOME/IP Message transported via TCP, the SOME/IP Magic Cookie Message (Figure 4.7) may be inserted into the SOME/IP messages over TCP message stream at regular distances.] (RS_SOMEIP_00010)

[PRS_SOMEIP_00160] [The layout of the Magic Cookie Messages is shown in Figure 4.7.] (RS_SOMEIP_00010)
### 4.2.1.3 Multiple Service-Instances

**[PRS_SOMEIP_00162]** Service-Instances of the same Service are identified through different Instance IDs. It shall be supported that multiple Service-Instances reside on different ECUs as well as multiple Service-Instances of one or more Services reside on one single ECU. *(RS_SOMEIP_00011)*

**[PRS_SOMEIP_00163]** While different Services shall be able to share the same port number of the transport layer protocol used, multiple Service-Instances of the same service on one single ECU shall listen on different ports per Service-Instance. *(RS_SOMEIP_00011)* Rationale: While Instance IDs are used for Service Discovery, they are not contained in the SOME/IP header.

A Service Instance can be identified through the combination of the Service ID combined with the socket (i.e. IP-address, transport protocol (UDP/TCP), and port number). It is recommended that instances use the same port number for UDP and TCP. If a service instance uses UDP port x, only this instance of the service and not another instance of the same service should use exactly TCP port x for its services.
4.2.1.4 Transporting large SOME/IP messages of UDP (SOME/IP-TP)

The UDP binding of SOME/IP can only transport SOME/IP messages that fit directly into an IP packet. If larger SOME/IP messages need to be transported over UDP (e.g. of 32 KB) the SOME/IP Transport Protocol (SOME/IP-TP) shall be used. The SOME/IP message too big to be transported directly with the UDP binding shall be called "original" SOME/IP message. The "pieces" of the original SOME/IP message payload transported in SOME/IP-TP messages shall be called "segments".

Use TCP only if very large chunks of data need to be transported (> 1400 Bytes) and no hard latency requirements in the case of errors exists

[PRS_SOMEIP_00720] SOME/IP messages using SOME/IP-TP shall activate Session Handling (Session ID must be unique for the original message).  
(RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00721] All SOME/IP-TP segments shall carry the Session ID of the original message; thus, they have all the same Session-ID.  
(RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00722] SOME/IP-TP segments shall have the TP-Flag of the Message Type set to 1.  
(RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00723] SOME-IP-TP-Header is as shown in Figure 4.8. SOME/IP-TP segments shall have a TP header right after the SOME/IP header (i.e. before the SOME/IP payload) with the following structure (bits from highest to lowest):

- Offset [28 bits]
- Reserved Flag [1 bit]
- Reserved Flag [1 bit]
- Reserved Flag [1 bit]
- More Segments Flag [1 bit]  
(RS_SOMEIP_00010, RS_SOMEIP_00011)
The Offset field shall transport the upper 28 bits of a uint32. The lower 4 bits shall be always be interpreted as 0. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \) **Note:**
This means that the offset field can only transport offset values that are multiples of 16 bytes.

The Offset field of the TP header shall be set to the offset in bytes of the transported segment in the original message. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \)

The Reserved Flags shall be set to 0 by the sender and shall be ignored (and not checked) by the receiver. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \)

The More Segments Flag shall be set to 1 for all segments but the last segment. For the last segment it shall be set to 0. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \)

The SOME/IP length field shall be used as specified before. This means it covers the first 8 bytes of the SOME/IP header and all bytes after that. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \) **Note:**
This means that for a SOME/IP-TP message transporting a segment, the SOME/IP length covers 8 bytes of the SOME/IP header, the 4 bytes of the TP header, and the segment itself.

The length of a segment must reflect the alignment of the next segment based on the offset field. Therefore, all but the last segment shall have a length that is a multiple of 16 bytes. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \)

Since UDP-based SOME/IP messages are limited to 1400 bytes payload, the maximum length of a segment that is correctly aligned is 1392 bytes. \( \text{(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)} \)
SOME/IP-TP messages shall use the same Message ID (i.e. Service ID and Method ID), Request ID (i.e. Client ID and Session ID), Protocol Version, Interface Version, and Return Code as the original message.  

(RS_SOMEIP_00010, RS_SOMEIP_00011) Note: As described above the Length, Message Type, and Payload are adapted by SOME/IP-TP.

4.2.1.4.1 Example

This example describes how an original SOME/IP message of 5880 bytes payload has to be transmitted. The Length field of this original SOME/IP message is set to \(8 + 5880\) bytes.

```
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>

</tr>
</thead>
<tbody>
<tr>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
<td>0x01000009</td>
<td>= 8 + 5880</td>
<td>0x00000005</td>
<td>0x01</td>
<td>0x01</td>
<td>b00000000</td>
<td>0x00</td>
</tr>
</tbody>
</table>
```

Payload [5880 Bytes]  
0x00 0x00 0x30 0x00  
0x00 0x01 0x02 0x03  

...  

Figure 4.9: Example: Header of Original SOME/IP message

This original SOME/IP message will now be segmented into 5 consecutive SOME/IP segments. Every payload of these segments carries at most 1392 bytes in this example.

For these segments, the SOME/IP TP module adds additional TP fields (marked red). The Length field of the SOME/IP carries the overall length of the SOME/IP segment including 8 bytes for the Request ID, Protocol Version, Interface Version, Message Type and Return Code. Because of the added TP fields (4 bytes), this Length information is extended by 4 additional SOME/IP TP bytes.

The following figure provides an overview of the relevant SOME/IP header settings for every SOME/IP segment:
Figure 4.10: Example: Overview of relevant SOME/IP TP headers

Note:
Please be aware that the value provided within the Offset Field is given in units of 16 bytes, i.e.: The Offset Value of 87 correspond to 1392 bytes Payload.

The complete SOME/IP headers of the SOME/IP segments message will look like this in detail:

- The first 4 segments contain 1392 Payload bytes each with "More Segments Flag" set to '1':

Figure 4.11: Example: Header of the SOME/IP segments

- The last segment (i.e. #5) contains the remaining 312 Payload bytes of the original 5880 bytes payload. This last segment is marked with "More Segments flag" set to '0'.

</tbody>
</table>
4.2.1.4.2 Sender specific behavior

[PRS_SOMEIP_00732] The sender shall segment only messages that were configured to be segmented. (RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00733] The sender shall send segments in ascending order. (RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00734] The sender shall segment in a way that all segments with the More Segment Flag set to 1 are of the same size. (RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00735] The sender shall try to maximize the size of segments within limitations imposed by this specification. (RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00736] The sender shall not send overlapping or duplicated segments. (RS_SOMEIP_00010, RS_SOMEIP_00011)

4.2.1.4.3 Receiver specific behavior

[PRS_SOMEIP_00738] The receiver shall match segments for reassembly based on the configured values of Message-ID, Protocol-Version, Interface-Version and Message-Type (w/o TP Flag). (RS_SOMEIP_00010, RS_SOMEIP_00011)

[PRS_SOMEIP_00740] It shall be supported to reassemble multiple messages with the same Message ID but sent from different clients (difference in Sender IP, Sender
Port, or Client ID) in parallel. This should be controlled by configuration and determines the amount of "reassembly buffers". \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00741] The Session ID shall be used to detect the next original message to be reassembled. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00742] The receiver shall start a new reassembly (and may be throw away old segments that were not successfully reassembled), if a new segment with a different Session-ID is received. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00743] The receiver should only reassemble up to its configured buffer size and skip the rest of the message. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00744] Only correctly reassembled message of up to the configured size shall be passed to an application. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

Note: This means that the implementation must make sure that all bytes of the message must be bytes that were received and reassembled correctly. Counting non-overlapping, non-duplicated bytes and comparing this to the length could be a valid check.

[PRS\_SOMEIP\_00745] The Return Code of the last segment used for reassembly shall be used for the reassembled message. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00746] During reassembling the SOME/IP TP segments into a large unsegmented message, the Message Type shall be adapted, the TP Flag shall be reset to 0. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00747] The receiver shall support reassembly of segments that are received in ascending and descending order. \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

[PRS\_SOMEIP\_00748] The receiver should use limited resources to support reassembly of reordered segments of a single original message. At least a reorder distance of 3 shall be supported (i.e. segments are allowed up to 3 positions away from their correct place in sequence). \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

Note: This could mean for example that the receiver can only desegment if segments are in order but it stores the last 4 segments and sorts them before trying to deserialize. Or it could mean that all segments are written into a buffer and 4 meta-data structures (e.g. start and length) to store which data of the buffer is valid are present.

[PRS\_SOMEIP\_00749] The receiver shall cancel desegmentation for a single original message, if missing segments of this original message are detected and resources do not permit to further wait on the segment (e.g. because the next message already starts or reorder distance is higher than expected). \[(RS\_SOMEIP\_00010, RS\_SOMEIP\_00011)\]

Note: This means that reordering inside a single original message is allowed, if resources permit this.
Interleaving of different segmented messages using the same buffer (e.g. only the Session-ID and payload are different) is not supported. \([RS\_SOMEIP\_00010, RS\_SOMEIP\_00011]\)

**Note:** This prohibits that equal events (same Message-ID, IP-Addresses, ports numbers, and transport protocol) arrive in the wrong order, when some of their segments get re-ordered.

Reordering of segments of completely different original messages (e.g. Message ID is different) is not of concern since those segments go to different buffers. \([RS\_SOMEIP\_00010, RS\_SOMEIP\_00011]\)

The receiver shall correctly reassemble overlapping and duplicated segments by overwriting based on the last received segment. \([RS\_SOMEIP\_00010, RS\_SOMEIP\_00011]\)

The receiver may cancel reassembly, if overlapping or duplicated segments change already written bytes in the buffer, if this feature can be turned off by configuration. \([RS\_SOMEIP\_00010, RS\_SOMEIP\_00011]\)

The receiver shall be able to detect and handle obvious errors gracefully. E.g. cancel reassembly if segment length of a segment with MS=1 is not a multiple of 16. \([RS\_SOMEIP\_00010, RS\_SOMEIP\_00011]\)

**Note:** This means that buffer overflows or other malfunction shall must be prevented by the receiving code.

### 4.2.2 Request/Response Communication

One of the most common communication patterns is the request/response pattern. One communication partner (Client) sends a request message, which is answered by another communication partner (Server).

For the SOME/IP request message the client has to do the following for payload and header:

- Construct the payload
- Set the Message ID based on the method the client wants to call
- Set the Length field to 8 bytes (for the part of the SOME/IP header after the length field) + length of the serialized payload
- Optionally set the Request ID to a unique number (shall be unique for client only)
- Set the Protocol Version according \([PRS\_SOMEIP\_00052]\)
- Set the Interface Version according to the interface definition
- Set the Message Type to **REQUEST** (i.e. **0x00**)
• Set the Return Code to \(0x00\)

\((RS\_SOMEIP\_00007)\)

[PRS\_SOMEIP\_00921] ▶ To construct the payload of a request message, all input or inout arguments of the method shall be serialized according to the order of the arguments within the signature of the method. \((RS\_SOMEIP\_00007)\)

[PRS\_SOMEIP\_00922] ▶ The server builds the header of the response based on the header of the client’s request and does in addition:

- Construct the payload
- take over the Message ID from the corresponding request
- Set the length to the 8 Bytes + new payload size
- take over the Request ID from the corresponding request
- Set the Message Type to \(\text{RESPONSE} \) (i.e. \(0x80\)) or \(\text{ERROR} \) (i.e. \(0x81\))
- set Return Code to the return code of called method or in case of an Error message to a valid error code (see Table 4.11)

\((RS\_SOMEIP\_00007)\)

[PRS\_SOMEIP\_00923] ▶ To construct the payload of a response message, all output or inout arguments of the method shall be serialized according to the order of the arguments within the signature of the method. \((RS\_SOMEIP\_00007)\)

[PRS\_SOMEIP\_00927] ▶ A server shall not sent a response message for a request with a specific Request ID until the corresponding request message has been received.

\((RS\_SOMEIP\_00007)\)

[PRS\_SOMEIP\_00928] ▶ A client shall ignore the reception of a response message with a specific Request ID, when the corresponding request message has not yet been sent completely. \((RS\_SOMEIP\_00007)\)

4.2.3 Fire&Forget Communication

Requests without response message are called fire&forget.

[PRS\_SOMEIP\_00924] ▶ For the SOME/IP request-no-return message the client has to do the following for payload and header:

- Construct the payload
- Set the Message ID based on the method the client wants to call
- Set the Length field to 8 bytes (for the part of the SOME/IP header after the length field) + length of the serialized payload
- Optionally set the Request ID to a unique number (shall be unique for client only)
- Set the Protocol Version according to [PRS_SOMEIP_00052]
- Set the Interface Version according to the interface definition
- Set the Message Type to REQUEST_NO_RETURN (i.e. 0x01)
- Set the Return Code to 0x00

[PRS_SOMEIP_00006]

Fire & Forget messages shall not return an error. Error handling and return codes shall be implemented by the application when needed. [RS_SOMEIP_00006]

4.2.4 Notification Events

Notifications describe a general Publish/Subscribe-Concept. Usually the server publishes a service to which a client subscribes. On certain cases the server will send the client an event, which could be for example an updated value or an event that occurred.

SOME/IP is used only for transporting the updated value and not for the publishing and subscription mechanisms. These mechanisms are implemented by SOME/IP-SD.

[PRS_SOMEIP_00925] For the SOME/IP notification message the client has to do the following for payload and header:

- Construct the payload
- Set the Message ID based on the event the server wants to send
- Set the Length field to 8 bytes (for the part of the SOME/IP header after the length field) + length of the serialized payload
- Set the Request ID to 0x0
- Set the Protocol Version according to [PRS_SOMEIP_00052]
- Set the Interface Version according to the interface definition
- Set the Message Type to NOTIFICATION (i.e. 0x02)
- Set the Return Code to 0x00

[RS_SOMEIP_00004]

The payload of the notification message shall consist of the serialized data of the event. [RS_SOMEIP_00004]

When more than one subscribed client on the same ECU exists, the system shall handle the replication of notifications in order to save transmissions on the communication medium. This is especially important, when notifications are transported using multicast messages.
4.2.4.1 Strategy for sending notifications

For different use cases different strategies for sending notifications are possible. The following examples are common:

- Cyclic update — send an updated value in a fixed interval (e.g. every 100 ms for safety relevant messages with Alive)
- Update on change — send an update as soon as a "value" changes (e.g. door open)
- Epsilon change — only send an update when the difference to the last value is greater than a certain epsilon. This concept may be adaptive, i.e. the prediction is based on a history; thus, only when the difference between prediction and current value is greater than epsilon an update is transmitted.

4.2.5 Fields

A field represents a status and has a valid value. The consumers subscribing for the field instantly after subscription get the field value as an initial event.

[PRS_SOMEIP_00179] A field shall be a combination of getter, setter and notification event.

[PRS_SOMEIP_00180] A field without a setter and without a getter and without a notifier shall not exist. The field shall contain at least a getter, a setter, or a notifier.

[PRS_SOMEIP_00181] The getter of a field shall be a request/response call that has an empty payload in the request message and the value of the field in the payload of the response message.

[PRS_SOMEIP_00182] The setter of a field shall be a request/response call that has the desired value of the field in the payload of the request message and the value that was set to the field in the payload of the response message.

Note:
If the value of the request payload was adapted (e.g. because it was out of limits) the adapted value will be transported in the response payload.

[PRS_SOMEIP_00909] The notifier shall send an event message that transports the value of the field to the client when the client subscribes to the field.

[PRS_SOMEIP_00183] The notifier shall send an event message that transports the value of a field on change and follows the rules for events.
4.2.6 Error Handling

Error handling can be done in the application or the communication layer below. Therefore SOME/IP supports two different mechanisms:

- Return Codes in the Response Messages of methods
- Explicit Error Messages

Which one of both is used, depends on the configuration.

[PRS_SOMEIP_00901] Return Codes in the Response Messages of methods shall be used to transport application errors and the response data of a method from the provider to the caller of a method. *(RS_SOMEIP_00008)*

Note:
Please be aware that return codes of the Request and Response methods are not treated as errors from the point of view of SOME/IP. This means that the message type is still 0x80 if a request/response method exits with a return code not equal to 0x00 (message type is still 0x80 if ApplicationError of AUTOSAR ClientServerOperation is different from E_OK).

[PRS_SOMEIP_00902] Explicit Error Messages shall be used to transport application errors and the response data or generic SOME/IP errors from the provider to the caller of a method. *(RS_SOMEIP_00008)*

[PRS_SOMEIP_00903] If more detailed error information need to be transmitted, the payload of the Error Message (Message Type 0x81) shall be filled with error specific data, e.g. an exception string. Error Messages shall be sent instead of Response Messages. *(RS_SOMEIP_00008)*

This can be used to handle all different application errors that might occur in the server. In addition, problems with the communication medium or intermediate components (e.g. switches) may occur, which have to be handled e.g. by means of reliable transport.

All messages have a return code field in their header. (See chapter 4.1.1)

[PRS_SOMEIP_00904] Only responses (Response Messages (message type 0x80) and Error Messages (message type 0x81) shall use the return code field to carry a return code to the request (Message Type 0x00) they answer. *(RS_SOMEIP_00008)*

[PRS_SOMEIP_00905] All other messages than 0x80 and 0x81 (see Chapter 4.1.1.6) shall set this field to 0x00. *(RS_SOMEIP_00008)*

4.2.6.1 Return Code

[PRS_SOMEIP_00187] The return code shall be UINT8. *(RS_SOMEIP_00008)*

[PRS_SOMEIP_00191] Currently defined Return Codes are shown in Table 4.11
<table>

</tbody>
</table>

Table 4.11: Return Codes

Generation and handling of return codes shall be configurable.

A SOME/IP error message (i.e. return code 0x01 - 0x1f) shall not be answered with an error message.

4.2.6.2 Error Message

For more flexible error handling, SOME/IP allows a different message layout specific for Error Messages instead of using the message layout of Response Messages.

The recommended layout for the exception message is the following:

- Union of specific exceptions. At least a generic exception without fields needs to exist.
- Dynamic Length String for exception description.

Rationale: The union gives the flexibility to add new exceptions in the future in a type-safe manner. The string is used to transport human readable exception descriptions to ease testing and debugging.
The receiver of a SOME/IP message shall not return an error message for events/notifications. (RS_SOMEIP_00008)

The receiver of a SOME/IP message shall not return an error message for fire&forget methods. (RS_SOMEIP_00008)

The receiver of a SOME/IP message shall not return an error message for events/notifications and fire&forget methods if the Message Type is set incorrectly to Request or Response. (RS_SOMEIP_00008)

For Request/Response methods the error message shall copy over the fields of the SOME/IP header (i.e. Message ID, Request ID, and Interface Version) but not the payload. In addition Message Type and Return Code have to be set to the appropriate values. (RS_SOMEIP_00008)

4.2.6.3 Error Processing Overview

Error handling shall be based on the message type received (e.g. only methods can be answered with a return code) and shall be checked in a defined order of [PRS_SOMEIP_00195]. (RS_SOMEIP_00008)

For SOME/IP messages received over UDP, the following shall be checked:

- The UDP datagram size shall be at least 16 Bytes (minimum size of a SOME/IP message)
- The value of the length field shall be less than or equal to the remaining bytes in the UDP datagram payload

If one check fails, a malformed error shall be issued. (RS_SOMEIP_00008)

SOME/IP messages shall be checked based on the error processing as shown in Figure 4.13. This does not include the application based error handling but
just covers the error handling in messaging and RPC.  

Figure 4.13: Message Validation and Error Handling in SOME/IP

When one of the errors specified in [PRS_SOMEIP_00195] occurs while receiving SOME/IP messages over TCP, the receiver shall check the TCP connection and shall restart the TCP connection if needed.  

Rational:
Checking the TCP connection might include the following:

- Checking whether data is received for e.g. other Eventgroups.
- Sending out a Magic Cookie message and waiting for the TCP ACK.
- Reestablishing the TCP connection
4.2.6.4 Communication Errors and Handling of Communication Errors

When considering the transport of RPC messages different reliability semantics exist:

- Maybe — the message might reach the communication partner
- At least once — the message reaches the communication partner at least once
- Exactly once — the message reaches the communication partner exactly once

When using the above terms, in regard to Request/Response the term applies to both messages (i.e. request and response or error).

While different implementations may implement different approaches, SOME/IP currently achieves "maybe" reliability when using the UDP binding and "exactly once" reliability when using the TCP binding. Further error handling is left to the application.

For "maybe" reliability, only a single timeout is needed, when using request/response communication in combination of UDP as transport protocol. Figure 4.14 shows the state machines for "maybe" reliability. The client's SOME/IP implementation has to wait for the response for a specified timeout. If the timeout occurs SOME/IP shall signal E_TIMEOUT to the client application.

For "exactly once" reliability the TCP binding may be used, since TCP was defined to allow for reliable communication.

Figure 4.14: State Machines for Reliability "Maybe"
5 Configuration Parameters

Configuration Parameters are not handled and described in this document.
6 Protocol usage and guidelines

6.1 Choosing the transport protocol

SOME/IP supports User Datagram Protocol (UDP) and Transmission Control Protocol (TCP). While UDP is a very lean transport protocol supporting only the most important features (multiplexing and error detecting using a checksum), TCP adds additional features for achieving a reliable communication. TCP not only handles bit errors but also segmentation, loss, duplication, reordering, and network congestion.

Inside a vehicle many applications require very short timeout to react quickly. These requirements are better met using UDP because the application itself can handle the unlikely event of errors. For example, in use cases with cyclic data it is often the best approach to just wait for the next data transmission instead of trying to repair the last one. The major disadvantage of UDP is that it does not handle segmentation. Hence, only being able to transport smaller chunks of data.

Guideline:

- Use TCP only if very large chunks of data need to be transported (> 1400 Bytes) and no hard latency requirements in the case of errors exists
- Use UDP if very hard latency requirements (<100ms) in case of errors is needed
- Use UDP together with SOME/IP-TP if very large chunks of data need to be transported (> 1400 Bytes) and hard latency requirements in the case of errors exists
- Try using external transport or transfer mechanisms (Network File System, APIX link, 1722, ...) when they are more suited for the use case. In this case SOME/IP can transport a file handle or a comparable identifier. This gives the designer additional freedom (e.g. in regard to caching).

The transport protocol used is specified by the interface specification on a per-message basis. Methods, Events, and Fields should commonly only use a single transport protocol.

6.2 Transporting CAN and FlexRay Frames

SOME/IP should allow to tunnel CAN and FlexRay frames. However, the Message ID space needs to be coordinated between both use cases. The full SOME/IP Header shall be used for transporting/tunneling CAN/FlexRay.
6.3 Insert Padding for structs

If padding is necessary, the designer of the interface shall insert reserved/padding elements in the definition of the data types if needed for alignment, since the SOME/IP implementation shall not automatically add such padding.
