Specification of Health Monitoring

Document Title | Specification of Health Monitoring
--- | ---
Document Owner | AUTOSAR
Document Responsibility | AUTOSAR
Document Identification No | 850

Document Status | published
Part of AUTOSAR Standard | Foundation
Part of Standard Release | R19-11

### Document Change History

<table>
<thead>
<tr>
<th>Date</th>
<th>Release</th>
<th>Changed by</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2019-11-28 | R19-11  | AUTOSAR Release Management | • Clarifications in specification of supervisions  
  • Deleted parameter "number of instances" from HealthChannel and SupervisedEntity  
  • Removed SWS_HM_00071  
  • Changed Document Status from Final to published |
| 2019-03-29 | 1.5.1   | AUTOSAR Release Management | • Updated acronyms table  
  • Added chapter with not applicable requirements  
  • Added SWS_HM_00460 and SWS_HM_00461  
  • Updated traceability to requirements of RS Health Monitoring  
  • Moved figures out of requirement trace items |
| 2018-10-29 | 1.5.0   | AUTOSAR Release Management | • Added API for retrieving supervision status  
  • Clarified error recovery actions  
  • Modified parameter configuration  
  • Several editorial changes |
| 2018-03-29 | 1.4.0   | AUTOSAR Release Management | • Initial release as "draft" |

1 Introduction and functional overview

1.1 Input documents and related standards and norms

This document specifies the functionality on the **Health Monitoring**.

For this release, this document applies to Adaptive Platform only: alignment with Classic Platform will be done in a subsequent release.

**Health Monitoring** is required by [1, ISO 26262] (under the terms control flow monitoring, external monitoring facility, watchdog, logical monitoring, temporal monitoring, program sequence monitoring) and this specification is supposed to address all relevant requirements from this standard.

Health monitoring has the following error detection functions:

1. **Alive Supervision** - checking if Checkpoints happens with a correct frequency
2. **Deadline Supervision** - checking the delta time between two Checkpoints
3. **Logical Supervision** - checking for correct sequence of execution of Checkpoints
4. **Health Status Supervision** - checking if Health Status is valid

The **Health Monitoring** is supposed to be implemented by AUTOSAR classic platform and AUTOSAR adaptive platform. It may be implemented by other platforms as well.

The **Health Monitoring** requirements are specified in [2, RS HealthMonitoring].

2 Acronyms and abbreviations

The glossary below includes acronyms and abbreviations relevant to Health Monitoring that are not included in the AUTOSAR Glossary [3].

<table>
<thead>
<tr>
<th>Abbreviation / Acronym:</th>
<th>Description:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alive Indication</td>
<td>An indication of a Supervised Entity to signal its aliveness by calling a checkpoint used for Alive Supervision.</td>
</tr>
<tr>
<td>Alive Supervision</td>
<td>Kind of supervision that checks if a Supervised Entity executed in a correct frequency.</td>
</tr>
<tr>
<td>Checkpoint</td>
<td>A point in the control flow of a Supervised Entity where the activity is reported.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Deadline Supervision</td>
<td>Kind of supervision that checks if the execution time between two Checkpoints is within minimum/maximum time limit.</td>
</tr>
<tr>
<td>Final Checkpoint</td>
<td>The ending Checkpoint of a Graph. There can be zero or more Final Checkpoints for each Graph.</td>
</tr>
<tr>
<td>Global Supervision Status</td>
<td>Status that summarizes the Local Supervision Status of all Supervised Entities.</td>
</tr>
<tr>
<td>Graph</td>
<td>A set of Checkpoints connected through Transitions, where at least one of Checkpoints is an Initial Checkpoint. There is a path (through Transitions) between any two Checkpoints of the Graph.</td>
</tr>
<tr>
<td>Health Channel</td>
<td>Channel providing information about the health status of a (sub)system. This might be the Global Supervision Status of an application, the result any test routine or the status reported by a (sub)system (e.g. voltage monitoring, OS kernel, ECU status, ...).</td>
</tr>
<tr>
<td>Health Channel Supervision</td>
<td>Kind of supervision that checks if the health indicators registered by the supervised software are within the tolerances/limits.</td>
</tr>
<tr>
<td>Health Monitoring</td>
<td>Supervision of the software behaviour for correct timing and sequence.</td>
</tr>
<tr>
<td>Health Status</td>
<td>A set of states that are relevant to the supervised software (e.g. a Voltage State, an application state, the result of a RAM monitoring algorithm).</td>
</tr>
<tr>
<td>Health Status Supervision</td>
<td>Check if the health indicators registered by the supervised software are within the tolerances/limits.</td>
</tr>
<tr>
<td>Initial Checkpoint</td>
<td>The starting Checkpoint of a Graph. There can be one or more Initial Checkpoints for each Graph.</td>
</tr>
<tr>
<td>Logical Supervision</td>
<td>Kind of online supervision of software that checks if the software (Supervised Entity or set of Supervised Entities) is executed in the sequence defined by the programmer (by the developed code).</td>
</tr>
<tr>
<td>Local Supervision Status</td>
<td>Status that represents the current result of Alive Supervision, Deadline Supervision and Logical Supervision of a single Supervised Entity.</td>
</tr>
<tr>
<td>Machine</td>
<td>see [3] AUTOSAR Glossary</td>
</tr>
<tr>
<td>Platform Health Management</td>
<td>Health Monitoring for the Adaptive Platform</td>
</tr>
</tbody>

[2] Requirements on Health Monitoring
AUTOSAR_RS_HealthMonitoring

AUTOSAR_TR_Glossary

4 Constraints and assumptions

4.1 Limitations and conditions of use

- Support of multiple instanciation of Supervised Entities is platform specific and should be described in the platform specifications. Currently this is not supported for CP. ([RS_HM_09240])

- Support of multiple instanciation of checkpoints in a Supervised Entities instance is platform specific and should be described in the platform specifications. Currently this is not supported for CP. ([RS_HM_09241])

- Currently mode dependent supervision is not supported for Adaptive Platform.
4.2 Applicability to car domains

No restrictions.

5.1 Not applicable requirements

[SWS_HM_NA] These requirements are not applicable because of limitations. (RS_HM_09240, RS_HM_09241) See 4.1 for a description of the limitations.

6 Functional specification

6.1 Functional Overview

This section presents black-box functional overview of the Health Monitoring. It does not define any requirements nor details on the functionality.

6.1.1 Functional Interfaces

The Health Monitoring supervises the execution of a configurable number of Supervised Entities and it also supervises their Health Status. When it detects a violation of the configured temporal and/or logical constraints on program execution or a violation of the configured health constraints, it triggers the appropriate error handlers. Health Monitoring controls also the Watchdogs correspondingly, see Figure 6.1.

Figure 6.1: Scope of Health Monitoring

The Health Monitoring function can be split as a daisy chain. Each Health Monitoring instance has the same interface to Supervised Entities, Error handling and Watchdog. In addition, the interface between the instances of Health Monitoring is standardized as well - it carries the results of Health Monitoring as
well as "raw data" (Checkpoint IDs, Health Status together with necessary context information). Each instance adds some context-specific data to Checkpoints (e.g. process/task id).

In the example below (Figure 6.2), there are three instances of Health Monitoring, each having different usage scenarios.

![Figure 6.2: Scope of Health Monitoring Daisy Chain example](image)

The data exchanged between Health Monitoring instances is configurable.

These are known use cases for Health Monitoring instances:

- The first instance is typically the same process/executable/application as the Supervised Entity.
- Further instance(s) can be realized as services/daemons on the microcontroller
- Further or final instance can be realized on a remote machine.

### 6.1.2 Basic concepts - Supervised Entities, Checkpoints, Graphs, Supervision Mode

The Health Monitoring supervises the execution of software. The logical units of supervision are Checkpoints that belong to Supervised Entities. There is no fixed relationship between Supervised Entities and the architectural building blocks software, but typically a Supervised Entity may represent one software component.

The Checkpoints and Transitions between the Checkpoints form a Graph. The Checkpoints of a graph can belong to the same Supervised Entity or to different Supervised Entities.
The Health Monitoring shall supervise graphs with checkpoints belonging to the same or different Supervised Entities. (RS_HM_09242, RS_HM_09249)

The Health Monitoring shall simultaneously supervise graphs of Supervised Entities preempted by other Supervised Entities. (RS_HM_09243, RS_HM_09249)

A Graph may have one or more initial Checkpoints and one or more final Checkpoints. Any sequence of starting with any Initial Checkpoint and finishing with any Final Checkpoint is correct (assuming that the checkpoints belong to the same Graph). After the final Checkpoint, any initial Checkpoint can be reported.

At runtime, Health Monitoring verifies if the configured Graphs are executed. This is called Logical Supervision. Health Monitoring verifies also the timing of Checkpoints and Transitions. The mechanism for periodic Checkpoints is called Alive Supervision and for aperiodic Checkpoints it is called Deadline Supervision.

The granularity of Checkpoints is not fixed by the Health Monitoring. Few coarse-grained Checkpoints limit the detection abilities of the Health Monitoring. For example, for an application with only one Checkpoint the Health Monitoring is only capable of detecting that this application (or one part of this application) is cyclically running and check the timing constraints. In contrast, if that application has Checkpoints at each block and branch, the Health Monitoring may also detect failures in the control flow of that application. Fine granularity of Checkpoints causes a complex and large configuration of the Health Monitoring.

Health Monitoring allows the definition of different Supervision Modes. Different behavior of supervision functions can be configured for each Supervision Mode.

6.1.3 Execution of Supervision Functions

Health Monitoring offers Alive Supervision, Deadline Supervision, Logical Supervision and Health Channel Supervision. All supervision functions can be invoked independently.

6.1.3.1 Alive Supervision

Periodic Supervised Entities have constraints on the number of times they are executed within a given time span. By means of Alive Supervision, The Health Monitoring checks periodically if the Checkpoints of a Supervised Entity have been reached within the given limits. This means that Health Monitoring checks if a Supervised Entity is run not too frequently or not too rarely.
6.1.3.2 Deadline Supervision

Non-cyclic Supervised Entities have individual constraints on the timing between two Checkpoints. By means of Deadline Supervision, Health Monitoring checks the time span of transitions between two Checkpoints of a Supervised Entity. This means that Health Monitoring checks if some steps in a Supervised Entity take a time that is within the configured minimum and maximum limits.

6.1.3.3 Logical Supervision

Logical Supervision is a fundamental technique for checking the correct execution of embedded system software. Please refer to the safety standards (IEC 61508 or ISO26262) when Logical Supervision is required. Logical Supervision focuses on control flow errors, which cause a divergence from the valid (i.e. coded/-compiled) program sequence during the error-free execution of the application. An incorrect control flow occurs if one or more program instructions are processed either in the incorrect sequence or are not even processed at all. Control flow errors can lead to data corruption, microcontroller resets, or fail-silence violations.

For the control flow graph this implies that every time the Supervised Entity reports a new Checkpoint, it must be verified that there is a Transition configured between the previous Checkpoint and the reported one.

6.1.3.4 Health Channel Supervision

Using Health Channel Supervision the system integrator can hook external and debounced supervision results to the Health Monitoring. The platform integrator can create rules to resolve the dependencies between these supervision results and derive actions when these rules evaluate to true or false. External supervision can be routines like RAM test, ROM test, kernel status, Voltage monitoring etc.

6.1.4 Determination of Supervision Status

Based on the results of the Alive, Deadline and Logical supervision functions, the Local Supervision Status of Supervised Entities and a Global Supervision Status is calculated. Each status is determined by a state machine.

The Local Supervision Status is calculated for each Supervised Entity and a Global Supervision Status is calculated based on the Local Supervision Status of all Supervised Entities.
6.1.5 Determination of Actions

6.1.5.1 Rule Processing

Based on the results of supervision functions, Health Monitoring determines the corresponding reaction.

6.1.5.2 Watchdog Control

Health Monitoring controls the hardware watchdog. When the Supervised Entities are not correctly evaluated due to a programming error or memory failure in the watchdog protocol itself, it may still happen that the watchdog protocol erroneously sets the triggering condition and no watchdog reset will be caused. Therefore, it may be needed to use Supervised Entities and Checkpoints (or some other internal supervision mechanism) within watchdog protocol itself, while avoiding recursion in watchdog protocol.

6.1.5.3 Error Handling

Depending on the Local Supervision Status of each Supervised Entity and on the Global Supervision Status, the Health Monitoring initiates a number of mechanisms to recover from supervision failures. These range from local error recovery within the Supervised Entity to a global reset of the ECU.

6.1.6 Functional Decomposition

The Health Monitoring has the following logical steps:

1. Execution of all Supervision Functions - see 6.2
2. Determination of Supervision Status - see 6.3
3. Determination of Actions - see 6.4

The behavior of Health Monitoring is mode-dependent (see description of supervision mode in 6.1.2 and [2]).
The Alive, Deadline and Logical supervision mechanisms supervise each Supervised Entity. A Supervised Entity may have between one and three mechanisms enabled. Based on the results from each of enabled mechanisms, the status of the Supervised Entity (called Local Status) is computed.

When the status of each Supervised Entity is determined, then based on each Local Supervision Status, the status of all Supervised Entities is determined (called Global Supervision Status).

Based on the results of Supervisions Functions (correct/incorrect), the Local Status of each Supervised Entity is determined by means of the Local Supervision Status state machine (6.11).

Based on Local Supervision Status of each Supervised Entity, the Global Supervision Status is determined by means of Global Supervision Status state machine (6.12).

Based on the Global Supervision Status, the error handling and watchdog handling take place (see Chapter 6.4).
6.2 Execution of Supervision Functions and Determination of Supervision Results

Supervised Entities are the units of supervision for the Health Monitoring. Each Supervised Entity (SupervisedEntity) can be supervised by a different supervision function or a combination of them.

The following three supervision functions are executed at this stage:

- Alive Supervision (see 6.2.1)
- Deadline Supervision (see 6.2.2)
- Logical Supervision (see 6.2.3)

Each of three Supervision Functions results with a list of Results of Supervision Function for each Supervised Entity (SupervisedEntity) (highlighted in Blue on Figure 6.3), where each Result is either correct or incorrect.

At Health Monitoring initialization, all the Results are set to correct. This means that for every Supervised Entity (SupervisedEntity) there are three partial results (one from Alive Supervision, one from Deadline Supervision and one from Logical Supervision).

In a given mode, each Supervised Entity (SupervisedEntity) may have zero, one or more Alive Supervisions (AliveSupervision), each having one correct/incorrect result.

In a given mode, each Supervised Entity (SupervisedEntity) may have zero, one or more Deadline Supervisions (DeadlineSupervision), each having one correct/incorrect result.

In a given mode, each Supervised Entity (SupervisedEntity) may have zero, one or more Logical Supervisions (LogicalSupervision) (i.e. graphs) configured, each having one correct/incorrect result.

In case there are zero active supervisions in a given mode, then Health Monitoring sees no EXPIRED local stati, so the watchdog trigger condition can be invoked.

6.2.1 Alive Supervision

The Alive Supervision (AliveSupervision) offers a mechanism to periodically check the execution reliability of one or several Supervised Entities. This mechanism supports a check of cyclic timing constraints of independent Supervised Entities.
6.2.1.1 Alive Supervision Configuration

To provide Alive Supervision (AliveSupervision), the Checkpoints and their timing constraints need to be configured. The simplest configuration for AliveSupervision is one Checkpoint without any Transitions, as shown in Figure 6.4)

![Simplest Alive Supervision Checkpoint Configuration](image)

Figure 6.4: Simplest Alive Supervision Checkpoint Configuration for a given Supervision Mode

Moreover, it is also possible to have more than one Checkpoint as shown in Figure 6.5)
Figure 6.5: Multiple Checkpoints for Alive Supervision in one SupervisedEntity for a given Supervision Mode
Each Checkpoint can have its own set of AliveSupervision Parameters. Transitions are not used by AliveSupervision. Although each Checkpoint has its own parameters, it is the SupervisedEntity for which status is determined based on the frequency of Checkpoints.

The parameters of the AliveSupervision depend on the Supervision Mode and are defined per Checkpoint (and not globally for the whole SupervisedEntity).

None, some, or all of the Checkpoints of a SupervisedEntity can be configured for AliveSupervision in a given Mode. Moreover, in each Mode the AliveSupervision options of Checkpoints can be different.

The ExpectedAliveIndications (EAI) specifies the amount of expected alive indications from a given Checkpoint, within a fixed period of supervision cycles. The period length is defined by AliveReferenceCycle.

An acceptable negative variation (MinMax) and acceptable positive variation (MaxMargin) can be configured.

The Health Monitoring has to support a configurable amount of independent Supervised Entities.

### 6.2.1.2 Alive Supervision Algorithm

To send an Alive Indication, a Supervised Entity (SupervisedEntity) invokes the function ReportCheckpoint, which results with incrementation of an Alive Counter for the Checkpoint.

The periodic examination of the Counter of each Checkpoint of a SupervisedEntity by the Health Monitoring happens at every AliveReferenceCycle.

The Alive Reference Cycle (see AliveReferenceCycle) is the property of an AliveSupervision of a Checkpoint in a given Supervision Mode.

[SWS_HM_00098] The Health Monitoring shall perform for each Alive Supervision (AliveSupervision) configured in the active Mode, the examination of the Alive Counter of each Checkpoint of the SupervisedEntity. The examination shall be done at the period AliveReferenceCycle of the corresponding Alive Supervision (AliveSupervision).\(^1\) [RS_HM_09125, RS_HM_09249]

[SWS_HM_00074] The Health Monitoring shall examine an Alive Counter by checking if it is within the allowed tolerance (Expected - Min Margin; Expected + Max Margin) (see ExpectedAliveIndications, MinMargin, MaxMargin).\(^1\) [RS_HM_09125, RS_HM_09249]

If any Checkpoint of a SupervisedEntity fails the examination, then the result of Alive Supervision for the SupervisedEntity is set to incorrect.
[SWS_HM_00115] If the Health Monitoring detects a deviation between the counted Alive Indications and the expected amount of alive indications (including tolerance margins), for any Checkpoint of a SupervisedEntity, then Alive Supervision at this AliveReferenceCycle for this SupervisedEntity shall be defined as incorrect. Otherwise, it shall be defined as correct. \((RS_{HM\_09125}, RS_{HM\_09249})\)

Health Monitoring only checks the Checkpoints that are configured for the current Supervision Mode.

[SWS_HM_00083] The Health Monitoring shall not perform the examination of the Alive Counter of a Checkpoint if no corresponding Alive Supervision (AliveSupervision) is defined in the current Supervision Mode. \((RS_{HM\_09125}, RS_{HM\_09249})\)

6.2.2 Deadline Supervision

Deadline Supervision (DeadlineSupervision) checks the timing constraints of non-cyclic Supervised Entities. In these Supervised Entities, a certain event happens and a following event happens within a given time span. This time span can have a maximum and minimum deadline (time window).

6.2.2.1 Deadline Supervision Configuration

For every DeadlineSupervision, two Checkpoints connected by a Transition are configured. The Deadline is attached to the Transition from the Source Checkpoint to the Target Checkpoint. The simplest DeadlineSupervision configuration contains two Checkpoints and one Transition, as shown in Figure 6.6)
More than one Transition can be defined in a SupervisedEntity. The Transitions and the Checkpoints do not have to form a closed graph. Since only the Source and the Target Checkpoints are considered by this Supervision Function, there can be independent graphs, as shown in Figure 6.7). Moreover, the Checkpoints can be chained.
The configuration of DeadlineSupervision is similar to the one of AliveSupervision.

The parameters of the Deadline Supervision (see DeadlineSupervision) depend on the Supervision Mode (ModeDependentSettings) and are defined for per a set of two Checkpoints. None, some, or all of the Checkpoints of a SupervisedEntity can be configured for DeadlineSupervision in a given Mode.

A DeadlineSupervision is defined as a set of Transitions with time constraints. A Transition is defined as two references to two Checkpoints, called Source Checkpoint and Target Checkpoint (see DeadlineSupervision). A Transition has minimum and maximum time MinDeadline, MaxDeadline.
6.2.2.2 Deadline Supervision Algorithm

When a Source Checkpoint (i.e. the Source Checkpoint referenced by the CheckpointTransition, see DeadlineSupervision) or a Target Checkpoint is reached, a SupervisedEntity invokes the function ReportCheckpoint, which results with the execution of DeadlineSupervision.

The DeadlineSupervision algorithm will calculate the time expired between the Source Checkpoint and the Target Checkpoint.

The calculation is performed either at the occurrence of the Target Checkpoint or at the moment the elapsed time after Source Checkpoint is above the maximum limit (MaxDeadline).

[SWS_HM_00294] If the time difference between the Target Checkpoint and the Source Checkpoint is not within the minimum and the maximum limits (MinDeadline and MaxDeadline), then the result of DeadlineSupervision for this SupervisedEntity shall be defined as incorrect. Otherwise, it shall be defined as correct. (RS_HM_09235, RS_HM_09249)

[SWS_HM_00228] If the Target Checkpoint is not reached before the maximum limit (MaxDeadline), then the result of DeadlineSupervision for this SupervisedEntity shall be defined as incorrect. (RS_HM_09235, RS_HM_09249)

[SWS_HM_00229] When a given Source Checkpoint is reached two or more times before the expiration of the maximum limit without reaching the corresponding Target Checkpoint, this shall be considered as an error and the result of the DeadlineSupervision for this SupervisedEntity shall be considered as incorrect. (RS_HM_09235, RS_HM_09249)

[SWS_HM_00354] When a given Target Checkpoint is reached before the occurrence of the corresponding Source Checkpoint, the function ReportCheckpoint [SWS_HM_00447] shall ignore this Checkpoint and not update the result of the Deadline Supervision for the Supervised Entity. (RS_HM_09235, RS_HM_09249)

This means also that it is not considered as an error by DeadlineSupervision if a given Target Checkpoint is reached several times in a sequence.

[SWS_HM_00299] For any reported Checkpoint that is neither a Source Checkpoint nor a Target Checkpoint, the function ReportCheckpoint shall ignore this Checkpoint and not update the result of the Deadline Supervision for the Supervised Entity. (RS_HM_09235, RS_HM_09249)

6.2.3 Logical Supervision

Logical Supervision checks if the code of Supervised Entities is executed in the correct sequence.
6.2.3.1 **Logical Supervision** Configuration

For every **Logical Supervision** (`LogicalSupervision`), there is a **Graph** of Checkpoints connected by Transitions. The **Graph** abstracts the behavior of the **SupervisedEntity**. There is a 1 to 1 correspondence between a **Graph** and the **LogicalSupervision** container.

In addition, a **Checkpoint** shall belong to maximum one **Graph**, overlapping **Graph** are not possible.

As an example for a **SupervisedEntity**, let us consider the following code fragment, which contains the Checkpoints CP0-0 to CP0-6.

```cpp
CP0-0: initialize();
CP0-1: while (subsystem is running) {
CP0-2:     if (condition_A)
CP0-3:         run subtask_A;
CP0-4:     else
CP0-5:         run subtask_B;
CP0-6:     run subtask_C;
```

**Figure 6.8: Example of Checkpoints**

This **SupervisedEntity** can be represented by the **Graph** shown in **Figure 6.9**.
A more abstract view of the SupervisedEntity is given by the Graph shown in Figure 6.10), where the Checkpoint CP0-1 represents the complete while loop.
In a `Graphs`, Checkpoints can belong to the same `SupervisedEntity` or to different `Supervised Entities`, no restriction is imposed. The transitions between Checkpoints in a Graph are dependent on the Supervision Mode.

The parameters of the `Graphs` (see `LogicalSupervision`) are the Transitions that are contained in a Supervision Mode (see `ModeDependentSettings`). Each Transition connects two Checkpoints. The Checkpoints exist irrespective if they are connected by any transitions.
6.2.3.2 **Logical Supervision Algorithm**

Immediately after initialization of the Health Monitoring, there has not yet been a Checkpoint reported, i.e. all the Supervised Entities are passive. Each Graph is considered as inactive.

Each Graph represents one Logical Supervision, but it may spans across possibly several Supervised Entities. Assuming N Graphs that cross a Supervised Entity, this implies N results from the Logical Supervision for the Supervised Entity.

[SWS_HM_00271] [The Health Monitoring shall maintain the activity status of each Graph.](RS_HM_09222, RS_HM_09249)

[SWS_HM_00296] [At the initialization, the Health Monitoring shall consider each Graph as inactive.](RS_HM_09222, RS_HM_09249)

Each Graph may have one or more Initial Checkpoints. Initial Checkpoints are Checkpoints with which a Graph can start.

To notify reaching a Checkpoint, a Supervised Entity invokes the function ReportCheckpoint, which results with execution of Logical Supervision algorithm.

Because a Checkpoint can belong to only one Graph, the function ReportCheckpoint is able to identify to which Graph a Checkpoint belongs.

[SWS_HM_00295] [The function ReportCheckpoint shall identify to which one Graph a reached Checkpoint belongs.](RS_HM_09222, RS_HM_09249)

If a Graph is active, the function ReportCheckpoint checks for each new Checkpoint if the Transition between the stored Checkpoint and the newly reported Checkpoint is allowed.

[SWS_HM_00252] [The function ReportCheckpoint shall verify if the reported Checkpoint belonging to a Graph is a correct one by the following checks:]

1. If the Graph of the reported Checkpoint is inactive, then:
   a. If the Checkpoint is an Initial Checkpoint (see Logical Supervision), then the result of this Logical Supervision within the Supervised Entity of the reported Checkpoint is correct, otherwise incorrect.

2. Else if the Graph is active and all previously called Checkpoints of this Graph were called in the right sequence, then:
   a. If the reported Checkpoint is a successor of the stored Checkpoint within the Graph of the reported Checkpoint (this means there is a Transition with Source and Target), then the result of this Logical Supervision for Supervised Entity of the reported Checkpoint is correct, otherwise incorrect.
3. Else (i.e. the Graph is active, but at least one Checkpoint in this Graph was previously called in a wrong sequence):
   a. The result of this Logical Supervision of the Supervised Entity keeps incorrect.

   The above requirement means that in case of an incorrect transition, the SupervisedEntity that is considered as erroneous is the one that reported the incorrect Checkpoint.

   \[ (RS_{HM\_09222}, RS_{HM\_09249}) \]

   If a Checkpoint is one of the initial Checkpoints of a Graph, then the Graph is set as active.

   Note that if a Graph contains multiple initial Checkpoints, either of them are allowed to be entered when the Graph is inactive: when an initial Checkpoint is reported, the corresponding Graph becomes active, so another initial Checkpoint is allowed only if a Transition is configured from the first Checkpoint to the second one as a Graph can have only one active checkpoint at a specific time.

   \[ [SWS_{HM\_00331}] \quad \text{If the result of the Logical Supervision triggered by ReportCheckpoint is correct and the Checkpoint is defined as a final one, then the function ReportCheckpoint shall set Graph as inactive. After a final checkpoint, only initial checkpoints are possible.} \] (RS_{HM\_09222}, RS_{HM\_09249})

   \[ [SWS_{HM\_00297}] \quad \text{If the function ReportCheckpoint determines that the result of the Logical Supervision for the given Checkpoint is true, and the Checkpoint is the initial one (see LogicalSupervision), then the Graph corresponding to the Checkpoint shall be considered as active.} \] (RS_{HM\_09222}, RS_{HM\_09249)

\[ [SWS_{HM\_00273}] \quad \text{For any reported Checkpoint that does not belong to any Graph, the function ReportCheckpoint shall ignore it and not update the result of the Logical Supervision for the SupervisedEntity.} \] (RS_{HM\_09222}, RS_{HM\_09249)

This is because the checkpoint may be used by other Supervision Functions (Alive or Deadline).

6.3 Determination of Supervision Status

Based on the Supervision Results determined in section 6.2, the Local Supervision Status and Global Supervision Status (see LocalSupervision and GlobalSupervision) is determined.

6.3.1 Determination of Local Supervision Status

The Local Supervision Status state machine determines the status of the SupervisedEntity. This is done based on the following:
1. Previous value of the Local Supervision Status,

2. Current values of: result of AliveSupervision, result of DeadlineSupervision, result of LogicalSupervision.

The change in the Local Status state machine is done at the time defined in 6.2.1.2, 6.2.2.2 and 6.2.3.2. The state machine is initialized at the initialization of the Health Monitoring.

[SWS_HM_00200] [The Health Monitoring shall track the Local Supervision Status of each SupervisedEntity.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249)

Figure 6.11. shows the state machine for Local Supervision Status of a SupervisedEntity with all possible states.

[SWS_HM_00441] [The Health Monitoring shall have the local statuses LOCAL_STATUS_OK, LOCAL_STATUS_DEACTIVATED, LOCAL_STATUS_EXPIRED and LOCAL_STATUS_FAILED.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See also figure 6.11.

![Local Supervision Status State Machine Diagram](image)
For the transitions between the states of the Local Supervision Status the following rules apply:

[SWS_HM_00268] [If Health Monitoring successfully initialized, then for each SupervisedEntity that is referenced from the Initial Supervision Mode (InitialMode) (i.e. each SupervisedEntity that is activated in the initial mode), the Health Monitoring shall set the Local Supervision Status for this SupervisedEntity to LOCAL_STATUS_OK and the counter for failed supervision reference cycles shall be set to zero (0).] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition 10 in figure 6.11.

[SWS_HM_00269] [If Health Monitoring successfully initialized, then for each SupervisedEntity that is not referenced from the Initial Mode (InitialMode), the Health Monitoring shall set the Local Supervision Status for this SupervisedEntity to LOCAL_STATUS_DEACTIVATED.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition 11 in figure 6.11.

If Health Monitoring successfully initialized and the parameter InitialMode of this SupervisedEntity in InitialMode is not configured to LOCAL_STATUS_OK then the Health Monitoring shall set the Local Supervision Status for this SupervisedEntity to LOCAL_STATUS_DEACTIVATED. (see Transition 11 in Figure 6.11).

[SWS_HM_00201] [If all values in three sets of results of Supervision (results of AliveSupervision, results of DeadlineSupervision, results of LogicalSupervision) for the SupervisedEntity are correct and the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_OK, then the Health Monitoring shall keep the SupervisedEntity in the Local Supervision Status LOCAL_STATUS_OK.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition 1 in Figure 6.11.

[SWS_HM_00202] [If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_OK AND:

1. (At least one result of AliveSupervision of the SupervisedEntity is incorrect and a Failure Tolerance of zero is configured (see configuration parameter FailedSupervisionCyclesTolerance) OR

2. If the result of at least one DeadlineSupervision of the SupervisedEntity or the result of at least one Logical Supervision of the SupervisedEntity is incorrect),

THEN the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_EXPIRED.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09163, RS_HM_09249) See Transition (2) in Figure 6.11.

The below requirements shows the important difference of AliveSupervision versus DeadlineSupervision and LogicalSupervision: the AliveSupervision has an error tolerance for failed reference cycles.

[SWS_HM_00203] [If the Supervised Entity was in Local Supervision Status LOCAL_STATUS_OK AND:
1. (If the result of at least one AliveSupervision of the SupervisedEntity is incorrect and a Failure Tolerance greater than zero is configured (see configuration parameter FailedSupervisionCyclesTolerance) AND

2. If all the results of DeadlineSupervision of the SupervisedEntity and all results of Logical Supervision of the SupervisedEntity are correct),

THEN the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_FAILED and increment the counter for failed supervision reference cycles.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09163, RS_HM_09249) See Transition (3) in Figure 6.11.

[SWS_HM_00204] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_FAILED AND:

1. (If the result of at least one AliveSupervision is incorrect and the counter for failed supervision reference cycles is less than the configured Failure Tolerance (see parameter FailedSupervisionCyclesTolerance) AND

2. If all the results of DeadlineSupervision of the SupervisedEntity and all the results of LogicalSupervision of the SupervisedEntity are correct),

THEN the Health Monitoring shall keep the Local Supervision Status in LOCAL_STATUS_FAILED and increment the counter for failed supervision reference cycles.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09163, RS_HM_09249) See Transition (4) in Figure 6.11

[SWS_HM_00300] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_FAILED AND:

1. (If all the results of AliveSupervision of the SupervisedEntity are correct and the counter for failed supervision reference cycles is > 1) AND

2. If all the results of DeadlineSupervision of the SupervisedEntity and all the results of LogicalSupervision of the SupervisedEntity are correct),

THEN the Health Monitoring shall keep the Local Supervision Status in LOCAL_STATUS_FAILED and decrement the counter for failed supervision reference cycles.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09163, RS_HM_09249) See Transition (4) in Figure 6.11.

[SWS_HM_00205] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_FAILED AND:

1. (If all the results of AliveSupervision of the SupervisedEntity are correct and the counter for failed supervision reference cycles equals 1) AND

2. If all the results of Deadline Supervisions of the SupervisedEntity and all the results of Logical Supervision of the SupervisedEntity are correct),

THEN the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_OK and decrement the counter for failed supervision reference cycles.]
See Transition (5) in Figure 6.11.

[SWS_HM_00206] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_FAILED AND:

1. (If at least one result of AliveSupervision is incorrect and the counter for failed supervision reference cycles is equal to the configured Failure Tolerance (see configuration parameter FailedSupervisionCyclesTolerance) OR

2. If at least one result of DeadlineSupervision of the SupervisedEntity or at least one the result of Logical Supervision of the SupervisedEntity is incorrect),

THEN the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_EXPIRED.

See Transition (6) in Figure 6.11.

[SWS_HM_00207] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_OK and there is a switch to a mode which deactivates the SupervisedEntity, then the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_DEACTIVATED.

See Transition (7) in Figure 6.11.

[SWS_HM_00291] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_FAILED and there is a switch to a mode in which the SupervisedEntity is Deactivated, then the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_DEACTIVATED.

See Transition (12) in Figure 6.11.

Note that the above requirement is only applicable for the LOCAL_STATUS_FAILED status, but not for LOCAL_STATUS_EXPIRED.

[SWS_HM_00208] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_DEACTIVATED, the functions ReportCheckpoint and the Health Monitoring shall not perform any Supervision Functions for this Supervised Entity and keep the Local Supervision Status in the state LOCAL_STATUS_DEACTIVATED.

See Transition (8) in Figure 6.11.

[SWS_HM_00209] If the SupervisedEntity was in Local Supervision Status LOCAL_STATUS_DEACTIVATED and there is a switch to a mode in which the SupervisedEntity is active, then the Health Monitoring shall change the Local Supervision Status to LOCAL_STATUS_OK and the counter for failed supervision reference cycles shall be set to zero (0).

See Transition (9) in Figure 6.11.
6.3.2 Determination of **Global Supervision Status**

Based on the Local Supervision Status of all Supervised Entities of a software subsystem, the Global Supervision Status is computed. There may be one or few Global Supervision Status on the whole software (but only one Global Supervision Status for a Classic Platform).

The Global Supervision Status has similar values as the Local Supervision Status. The main differences are the addition of the GLOBAL_STATUS_STOPPED value. Figure in Figure 6.12) shows the values and Transitions between them.

[SWS_HM_00440] [The Health Monitoring shall have the global statuses GLOBAL_STATUS_OK, GLOBAL_STATUS_DEACTIVATED, GLOBAL_STATUS_FAILED, GLOBAL_STATUS_EXPIRED, GLOBAL_STATUS_STOPPED.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See also Figure 6.12.
The Health Monitoring shall have one Global Supervision Status for a software subsystem. (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249)

The Global Supervision Status shall be statically initialized with GLOBAL_STATUS_DEACTIVATED. (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition (18) in Figure 6.12.

The Health Monitoring provides a feature to postpone the error reaction (the error reaction being not setting a correct trigger condition) for a configurable amount of time measured in multiples of the Supervision Cycle (Supervision cycle is the period at which the Health Monitoring is performed), named Expired Supervision Tolerance (see configuration parameter ExpiredSupervisionCyclesTolerance).
The Expired Supervision Tolerance is implemented within the state machine of the Global Supervision Status. The defined state machine is in the state GLOBAL_STATUS_EXPIRED while the blocking is postponed.

[SWS_HM_00214] [The Health Monitoring shall calculate the Global Supervision Status in every Supervision cycle. The function shall compute the Global Supervision Cycle after it computed every Local Supervision Status.

The cyclic update of Global Supervision Status is necessary to trigger the timely transition from GLOBAL_STATUS_EXPIRED to GLOBAL_STATUS_STOPPED.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249)

[SWS_HM_00285] [If the Health Monitoring was successfully initialized, the Global Supervision Status shall be set to GLOBAL_STATUS_OK and the Expired Cycle Counter shall be set to zero (0).](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition (13) in Figure 6.12.

[SWS_HM_00286] [If the Global Supervision Status was GLOBAL_STATUS_OK and the Health Monitoring is deactivated, then the Global Supervision Status shall be set to GLOBAL_STATUS_DEACTIVATED.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition (14), (15), (16) and (17) in Figure 6.12.

It has to be considered carefully that a deactivation of Health Monitoring when it is in states GLOBAL_STATUS_EXPIRED or GLOBAL_STATUS_STOPPED can hinder error reporting or error reaction.

[SWS_HM_00078] [If the Global Supervision Status was GLOBAL_STATUS_OK and the Local Supervision Status of all Supervised Entities are either LOCAL_STATUS_OK or LOCAL_STATUS_DEACTIVATED then the Health Monitoring shall keep the Global Supervision Status GLOBAL_STATUS_OK.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transitions(1) in Figure 6.12.

[SWS_HM_00076] [If the Global Supervision Status was GLOBAL_STATUS_OK, the Local Supervision Status of at least one Supervised Entity is LOCAL_STATUS_FAILED, and no Supervised Entity is in Local Supervision Status LOCAL_STATUS_EXPIRED, then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_FAILED.](RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition (2) in Figure 6.12.

The Health Monitoring supports a feature to delay the error reaction (switching to LOCAL_STATUS_EXPIRED) for a configurable amount of time. This could be used to allow clean-up activities before a watchdog reset, e.g. writing the error cause, writing NVRAM data.
If the Global Supervision Status was GLOBAL_STATUS_OK, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and the Expired Supervision Tolerance is configured to a value larger than zero (see configuration parameter ExpiredSupervisionCyclesTolerance), then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_EXPIRED and increment the Expired Cycle Counter.\(\text{(RS_HM}_09222, \text{RS_HM}_09125, \text{RS_HM}_09235, \text{RS_HM}_09163, \text{RS_HM}_09249)\) See Transition (3) in Figure 6.12.

If the Global Supervision Status was GLOBAL_STATUS_OK, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and the Expired Supervision Tolerance is configured to zero (see configuration parameter ExpiredSupervisionCyclesTolerance), then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_STOPPED.\(\text{(RS_HM}_09222, \text{RS_HM}_09125, \text{RS_HM}_09235, \text{RS_HM}_09163, \text{RS_HM}_09249)\) See Transition (4) in Figure 6.12.

If the Global Supervision Status was GLOBAL_STATUS_FAILED, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and no SupervisedEntity is in Local Supervision Status LOCAL_STATUS_EXPIRED, then the Health Monitoring shall remain in Global Supervision Status GLOBAL_STATUS_FAILED.\(\text{(RS_HM}_09222, \text{RS_HM}_09125, \text{RS_HM}_09235, \text{RS_HM}_09249)\) See Transition (5) in Figure 6.12.

If the Global Supervision Status was GLOBAL_STATUS_FAILED and the Local Supervision Status of all Supervised Entities is either LOCAL_STATUS_OK or LOCAL_STATUS_DEACTIVATED then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_OK.\(\text{(RS_HM}_09222, \text{RS_HM}_09125, \text{RS_HM}_09235, \text{RS_HM}_09249)\) See Transition (6) in Figure 6.12.

If the Global Supervision Status was GLOBAL_STATUS_FAILED, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and the Expired Supervision Tolerance is configured to a value larger than zero (see configuration parameter ExpiredSupervisionCyclesTolerance), then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_EXPIRED and increment the Expired Cycle Counter.\(\text{(RS_HM}_09222, \text{RS_HM}_09125, \text{RS_HM}_09235, \text{RS_HM}_09163, \text{RS_HM}_09249)\) See Transition (7) in Figure 6.12.
Specification of Health Monitoring

AUTOSAR FOR 19-11

Supervision Status to GLOBAL_STATUS_STOPPED.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09163, RS_HM_09249) See Transition (8) in Figure 6.12.

[SWS_HM_00219] [If the Global Supervision Status was GLOBAL_STATUS_EXPIRED, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and the Expired Cycle Counter is less than the configured Expired Supervision Tolerance (see configuration parameter ExpiredSupervisionCyclesTolerance), then the Health Monitoring shall keep Global Supervision Status GLOBAL_STATUS_EXPIRED and increment the Expired Cycle Counter.] (RS_HM_09163, RS_HM_09249) See Transition (9) in Figure 6.12.

[SWS_HM_00220] [If the Global Supervision Status was GLOBAL_STATUS_EXPIRED, the Local Supervision Status of at least one SupervisedEntity is LOCAL_STATUS_EXPIRED, and the Expired Cycle Counter is equal to the configured Expired Supervision Tolerance (see configuration parameter ExpiredSupervisionCyclesTolerance), then the Health Monitoring shall change the Global Supervision Status to GLOBAL_STATUS_STOPPED.] (RS_HM_09163, RS_HM_09249) See Transition (10) in Figure 6.12.

[SWS_HM_00221] [If the Global Supervision Status was GLOBAL_STATUS_STOPPED, then the Health Monitoring shall remain in Global Supervision Status GLOBAL_STATUS_STOPPED.] (RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09249) See Transition (11) in Figure 6.12.

6.3.3 Effect of changing Mode

The modes are statically configured and contained in the Health Monitoring configuration set. A mode switch changes the supervision parameters of the Supervised Entities.

[SWS_HM_00182] [If the current global status GLOBAL_STATUS_OK or GLOBAL_STATUS_FAILED then for each SupervisedEntity that is activated in the new mode, the Health Monitoring shall retain the current state of the SupervisedEntity. Switching to the mode where a SupervisedEntity is deactivated clears also errors that had resulted with the GLOBAL_STATUS_FAILED status.] (RS_HM_09253, RS_HM_09249)

A SupervisedEntity is considered as deactivated in a specific mode if in this mode no Alive nor Deadline Supervision nor Transition is set for this SupervisedEntity. On the contrary, if there is at least one Alive or Deadline or Transition supervision set for a SupervisedEntity in a specific mode, this SupervisedEntity is considered activated in that mode.

When switching mode, the Graph that is considered active in the new mode is the one that corresponds to the last reported Checkpoint. If the last reported Checkpoint
does not belong to any Graph, there is no active Graph and only Initial Checkpoints are considered as correct for the Logical Supervision.

[SWS_HM_00315]  If the current global status is GLOBAL_STATUS_OK or GLOBAL_STATUS_FAILED then for each SupervisedEntity that is deactivated in the new mode, the Health Monitoring shall change the state of the SupervisedEntity to LOCAL_STATUS_DEACTIVATED; It shall set its Results of Active, Deadline and Logical Supervision to correct; It shall also clear its failed reference cycle counter to 0. (RS_HM_09253, RS_HM_09249)

Executing a mode switch is possible when the Health Monitoring is in the state GLOBAL_STATUS_OK or GLOBAL_STATUS_FAILED. In other modes, changing the Supervision Mode has no effect.

[SWS_HM_00316]  If the current global status is not GLOBAL_STATUS_OK nor GLOBAL_STATUS_FAILED then the Health Monitoring shall not perform any actions at the Supervision Mode change. (RS_HM_09253, RS_HM_09249)

[SWS_HM_00139]  If changing the supervision mode fails, the Health Monitoring shall assume a global supervision failure and set the Global Supervision Status to GLOBAL_STATUS_STOPPED. (RS_HM_09253, RS_HM_09249) See Transition (12) in Figure 6.12.

### 6.4 Determination of Actions based on Supervision Status

#### 6.4.1 Concept of HealthChannel and HealthStatus

A **HealthChannel** can be the Global supervision status of the software under supervision.

A **HealthChannel** can be the result of an environment monitoring algorithm. Eg: Voltage Monitoring, Temperature Monitoring

A **HealthChannel** can be the result of a memory integrity test routine. Eg: RAM test, ROM test

A **HealthChannel** can be the status of the operating system or Kernel. Eg: Os Status, Kernel Status

A **HealthChannel** can be the status of another platform instance or Virtual Machine or ECU.

**HealthStatus** of a **HealthChannel** is the abstract format of the information that a **HealthChannel** provides to the Health Monitoring. Two different **HealthChannels** may have same **HealthStatus** names to represent its result. Eg: High, low, normal

The various external monitoring routines shall report their result or status in the form of defined **HealthStatus** to the Health Monitoring. The Health Monitoring
shall initiate the Arbitration using the indicated HealthStatus according to the configuration parameters defined in the configuration file. The Arbitration is composed of Conditions, LogicalExpressions and Rules. The Rules shall lead to execution of an ActionList.

![Figure 6.13: Determination of action based on the received HealthStatus](image)

As mentioned above, a HealthChannel can be Internal (Example: Global Supervision Status) or External (Example: Voltage, RAM Test, Kernel Status). The ActionList is determined in two steps. First step is called Arbitration - see 6.4.2, which consists of Conditions, LogicalExpressions and Rules. The second step is called DeterminationOfActions - see 6.4.3, where an ActionList is triggered based on if the Rule evaluates to TRUE or FALSE.

### 6.4.2 Arbitration of HealthChannels

Arbitration performed by the Health Monitoring is simple and rule-based. The Rules used for Arbitration are specified in the configuration of the Health Monitoring module.

The Rules are composed of trivial LogicalExpressions and the Arbitration is thus expected to have a low runtime impact.

In order to know what ActionList to execute, the Health Monitoring is required to detect changes in Arbitration results from previous Rule evaluation. How this is done, and the memory needed to store results, is implementation specific and not described in this document.
6.4.2.1 Arbitration Rules

A Rule is a LogicalExpression that is composed of a set of Conditions. The Rules are evaluated when the HealthStatus of a HealthChannel is changed, or during the execution of the Health Monitoring main function. The result of the evaluation (True or False) is used to decide about execution of the corresponding ActionList.

6.4.2.2 Conditions and LogicalExpressions.

The LogicalExpression that comprises a Rule can use different operators such as AND, OR, XOR, NOT and NAND. Each term in the LogicalExpression corresponds to a Condition. Each defined HealthChannel when informs the Health Monitoring about its HealthStatus, the Condition will verify if a requested HealthStatus is EQUAL or NOT_EQUAL to a certain HealthStatus.

An example Rule with two Conditions is shown in Figure 6.14. The Rules and the set of available logical operations are defined as a part of the Health Monitoring configuration.

```
Arbitration Rule:

If(HealthChannel1 = Status_A &&
   HealthChannel2 = Status_B ){
   Execute the True Action
}
else {
   Execute the False Action
}
```

Figure 6.14: Pseudocode representation of an example rule with two conditions.
6.4.2.3 Requirements of Arbitration

The Health Monitoring accepts HealthStatus requests as input for the Arbitration. HealthStatus requests normally originate from the application but may also originate from other Platform services such as the DM, EM.

[SWS_HM_00050] [The Application shall request HealthStatus using the Health Monitoring interface ReportHealthStatus.](RS_HM_09257, RS_HM_09249)

[SWS_HM_00051] [The Health Monitoring shall perform Arbitration based on incoming HealthStatus requests.](RS_HM_09255, RS_HM_09249)

[SWS_HM_00052] [All HealthStatus requests are handled in the same way by the Health Monitoring. They are configured by selection of the corresponding HealthStatus condition type in the configuration.](RS_HM_09255, RS_HM_09249)

[SWS_HM_00053] [The Health Monitoring shall perform Arbitration using configured Rules.](RS_HM_09255, RS_HM_09249)

[SWS_HM_00054] [The Arbitration Rules shall be configurable using the module configuration parameters.](RS_HM_09255, RS_HM_09249)

[SWS_HM_00055] [Health Monitoring is not allowed to use results of previous Arbitration Rule evaluations as input for the LogicalExpression.](RS_HM_09255, RS_HM_09249)

6.4.2.4 Arbitration Behavior after Initialization

The behavior of the Arbitration of Health Monitoring after initialization is controlled by the configuration container HealthStatusInitValue. This parameter may be configured once for each HealthChannel in the configuration.

[SWS_HM_00056] [If the container HealthStatusInitValue does not exist or the HealthChannel does not already have an initial value, the Health Monitoring shall treat the corresponding HealthStatus Condition as undefined and not use it for Arbitration until the corresponding HealthChannel has been updated for the first time.](RS_HM_09255, RS_HM_09249)

6.4.3 Determination of ActionList

The DeterminationOfActions part of Health Monitoring performs the execution of the ActionList based on the results of the Arbitration. An ActionList is executed by the Health Monitoring when triggered by a Rule.

[SWS_HM_00057] [The Health Monitoring is not required to store or react on any Platform module specific return values on its performed ActionItems.](RS_HM_09255, RS_HM_09249)
The Health Monitoring shall contain a single ActionList or no ActionList, if Rule evaluates to True. (RS_HM_09255, RS_HM_09249)

The Health Monitoring shall contain a single ActionList or no ActionList, if Rule evaluates to False. (RS_HM_09255, RS_HM_09249)

The Health Monitoring evaluates its Rules in the context of the Health Monitoring interface ReportHealthStatus. (RS_HM_09255, RS_HM_09249)

The corresponding ActionList is executed according to the selected execution method (see 6.4.3.1).

For each Rule of the Arbitration, Health Monitoring shall be able to execute different ActionList based on if the Rule evaluates to True or False. (RS_HM_09255, RS_HM_09249)

The ActionList associated with Rules evaluated in the context of the Health Monitoring interface ReportHealthStatus shall be executed by Health Monitoring synchronously. Care must be taken that it is not blocking the Health Monitoring for too long. (RS_HM_09255, RS_HM_09249)

### 6.4.3.1 Triggered and Conditional Execution

There are two ways that an ActionList may be executed based on evaluation of Rules. Either it is executed every time the Rule is evaluated with the corresponding result, or only when the evaluation result has changed from the previous evaluation. The execution method for an ActionList is configured using the ActionListExecution parameter (within the ActionList container).

If a True ActionList is configured for triggered execution (triggeredOnChange), the Health Monitoring shall only execute it when the evaluation of the corresponding Rule changes from False to True. (RS_HM_09255, RS_HM_09249)

If a False ActionList is configured for triggered execution (triggeredOnChange), the Health Monitoring shall only execute it when the evaluation of the corresponding Rule changes from True to False. (RS_HM_09255, RS_HM_09249)

If a True ActionList is configured for conditional execution (triggeredOnEvaluation), the Health Monitoring shall execute it every time the corresponding Rule is evaluated to True. (RS_HM_09255, RS_HM_09249)

If a False ActionList is configured for conditional execution (triggeredOnEvaluation), the Health Monitoring shall execute it every time the corresponding Rule is evaluated to False. (RS_HM_09255, RS_HM_09249)
6.4.3.2 Available ActionItems

The set of ActionItems that are available to use is predefined. The reason for this is to ease ECU configuration.

[SWS_HM_00068] [Health Monitoring shall be able to execute the predefined ActionItem defined by configuration container ActionItem.] (RS_HM_09159, RS_HM_09249)

[SWS_HM_00069] [The Health Monitoring shall execute a standard ActionItem mentioned below to recover from the failure.] (RS_HM_09159, RS_HM_09249)

6.4.3.2.1 Terminate or Restart Application

[SWS_HM_00070] [In Adaptive Platform the Health Monitoring shall invoke the standard interface defined in State Management module to request changing machine state or function group state or the standard interface defined in the Execution Management module to Restart a process.] (RS_HM_09251, RS_HM_09250, RS_HM_09249)

6.4.3.2.2 Reset Platform instance

[SWS_HM_00072] [Health Monitoring shall make use of a project specific driver interface or Hypervisor interface to reset the system, based on the complexity of the system.] (RS_HM_09169, RS_HM_09249)

6.4.3.2.3 Hardware Watchdog Reset

[SWS_HM_00073] [Health Monitoring shall use appropriate interface to periodically refresh the watchdog to prevent a watchdog reset.] (RS_HM_09244, RS_HM_09249)

[SWS_HM_00075] [When the Health Monitoring fails to refresh the watchdog, this automatically cause a watchdog reset (after the time needed to refresh the hardware watchdog elapse).] (RS_HM_09244, RS_HM_09249)

6.4.3.2.4 Notification Function

[SWS_HM_00079] [Health Monitoring shall invoke the configured notification mechanism to notify the Safety application to take an appropriate action.] (RS_HM_09159, RS_HM_09249)
6.4.3.3 Behavior of ActionList execution after Initialization

The behavior of the ActionList execution after initialization of the Health Monitoring is configured by the RuleInitState parameter (within the Rule container). It defines the "previous evaluation result" to be used when deciding on what ActionList to execute after the first evaluation of a Rule after initialization. The configuration parameter ActionListExecution (within the ActionList container) also affects the ActionList execution after initialization.

[SWS_HM_00080] [The Health Monitoring shall act according to what is stated in Table 6.1 when a Rule is evaluated for the first time after initialization.](RS_HM_09255, RS_HM_09249)

7 Health Monitoring API specification

This chapter specifies the API of Health Monitoring that is referred in other document parts. It is defined in generic/abstract way, so that it can be implemented on different platforms. In particular, the data types are not defined.

7.1 Provided API

7.1.1 Reporting Checkpoints and Health Status

[SWS_HM_00447] ReportCheckpoint [Health Monitoring shall provide a method to report the current code location, represented by a Checkpoint

    ReportCheckpoint(CheckpointID id)

](RS_HM_09254, RS_HM_09249)
7.1.2 Reporting health status

[SWS_HM_00448] ReportHealthStatus

Health Monitoring shall provide a method to report the health status information

`ReportHealthStatus(HealthStatusID id, HealthStatus status)`

(RS_HM_09257, RS_HM_09249)

7.1.3 Forwarding information between health monitoring components

[SWS_HM_00449] ReportHealthMonitoring

Health Monitoring shall provide a method to report the information collected and determined by one Health Monitoring component, so that they can be forwarded to another Health Monitoring component.

`ReportHealthMonitoring(HealthMonitoring monitoringData)`

(RS_HM_09159, RS_HM_09249)

7.1.4 Init / DeInit

[SWS_HM_00455] Init

Health Monitoring shall provide a method to initialize the service.

`Init()`

(RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09255, RS_HM_09249)

[SWS_HM_00456] DeInit

Health Monitoring shall provide a method to deinitialize the service.

`DeInit()`

(RS_HM_09222, RS_HM_09125, RS_HM_09235, RS_HM_09255, RS_HM_09249)

7.1.5 Retrieving Supervision Status from application

[SWS_HM_00457] GetLocalStatus

Health Monitoring shall provide a method to report the Local Status of a Supervised Entity to the application.

`GetLocalStatus(LocalStatusType* LocalStatus)`

(RS_HM_09237, RS_HM_09249)
[SWS_HM_00458] GetGlobalStatus  [Health Monitoring shall provide a method to report the Global Status to which the specified Supervised Entity belongs to the application.]

  GetGlobalStatus(GlobalStatusType* GlobalStatus)

[(RS_HM_09237, RS_HM_09249)]

7.2 Assumed API

This section specified an API that is used by Health Monitoring.

7.2.1 Triggering error handling

[SWS_HM_00450] TriggerErrorHandler  [Health Monitoring shall provide a method to trigger a defined error handler, providing the identifier of this error.]

  TriggerErrorHandler(ErrorID id)

[(RS_HM_09159, RS_HM_09249)]

7.2.2 Controlling watchdog

[SWS_HM_00451] SetWatchdogCondition  [Health Monitoring shall provide a method to control the watchdog drivers.]

  ControlWatchdog(ControlData control)

[(RS_HM_09244, RS_HM_09245, RS_HM_09246, RS_HM_09247, RS_HM_09248, RS_HM_09028, RS_HM_09226, RS_HM_09249)]

8 Configuration Parameters

This chapter specifies a configuration model of Health Monitoring. The options defined here are referenced/used in chapter 6.

This configuration, which is abstract and platform-independent is supposed to be implemented/instantiated by the specific platforms, e.g. by AUTOSAR AP.

8.1 Overall configuration

The configuration of a Machine (representing MCU, virtual machine, partition) is split into two categories:
1. ModeIndependentSettings - containing only static information: what are possible SupervisedEntities and possible HealthChannels

2. ModeDependentSettings - containing all supervision function configurations.

It means all supervision configuration is fully mode-dependent.

A system is made of several Machines. Therefore, Health Monitoring is allocated to a specific Machine.

It is possible that there are several independent suppliers of software for the same Machine. Therefore, each of suppliers can supply any part of the configuration, for any configuration classes.

ModeDependentSettings contains also the configuration of watchdogs - but this part is not standardized (marked in blue).

The definitions of Machines (machines/virtual machines/partitions) and Supervision Modes are assumed to be provided externally (by other specifications) therefore they are only referenced here.
Figure 8.1: Overall configuration
8.2 Mode-independent settings

ModeIndependentSettings contain static information: what are possible SupervisedEntitys and possible HealthChannel.

Implementation hint: This part of configuration is typically used to generate the type-safe API to Applications.

8.2.1 Supervised Entity

A SupervisedEntity is a collection of Checkpoints that can occur during the runtime of a software.

A SupervisedEntity has the following options:

1. Name: Globally unique name identifier, used by Applications
2. ID: Globally unique identifier (number)

Note that on AUTOSAR AP, the uniqueness of the name can be ensured by using a namespace as a part of the identification.

A Checkpoint has the following options:

1. Name: Name, used by Applications, unique within the SupervisedEntity.
2. ID: Identifier of the Checkpoint, unique within the SupervisedEntity.

Figure 8.2: Supervised Entity

Note: On AUTOSAR AP, a Supervised Entity results with an enum, named after the Supervised Entitys namespace and name, with the enumerations corresponding to the checkpoints.
8.2.2 **Health Channel**

*HealthChannel* is an information that is being monitored that has already been determined by the supplier and classified according to the possible health status values.

*HealthStatus* represents a possible value of the *HealthChannel*.

For example, a *HealthChannel* can be a "Motor Temperature" its *HealthChannels*: "HH", "H", "OK".

A *HealthChannel* has the following options:

1. **Name**: Globally unique name identifier, used by Applications.
2. **ID**: Globally unique identifier (number)
3. **HealthStatusInitValue**: Initial value of the corresponding Health Status.

A *HealthStatus* has the following options:

1. **Name**: Name, used by Applications, unique within the *HealthChannel*
2. **ID**: Identifier of the *HealthStatus*, unique within the *HealthChannel*.

![Diagram](image.png)

**Figure 8.3: Health Channel**

8.3 **Mode-dependent settings**

*ModeDependentSettings* contain all supervision function configurations.

Implementation hint: This part of configuration is typically used by non-generated code to perform the supervision at runtime.

8.3.1 **Alive Supervision**

*AliveSupervision* checks the amount of reported alive indications within the *AliveReferenceCycle*, which is to be within *ExpectedAliveIndications - MaxMargin* and *ExpectedAliveIndications - MaxMargin*.
**AliveSupervision** has the following options:

1. **AliveReferenceCycle**: time period at which the Alive Supervision mechanism compares the amount of received Alive Indications of the Checkpoint against the expected/configured amount.

2. **ExpectedAliveIndications**: the amount of expected alive indications of the Checkpoint within AliveReferenceCycle

3. **MaxMargin**: amount of acceptable missing alive indications within AliveReferenceCycle

4. **MinMargin**: amount of acceptable additional alive indications within AliveReferenceCycle

A Checkpoint uniquely identifies a specific location in source code. Different executions of the same code (e.g. due to multithreading or running the same application in several instances) share the same Checkpoint identification.

![Figure 8.4: Alive Supervision](image)

### 8.3.2 Deadline Supervision

**DeadlineSupervision** has the following options:

1. **MaxDeadline**: longest time span allowed.

2. **MinDeadline**: shortest time span allowed.

![Figure 8.5: Deadline Supervision](image)
8.3.3 Logical Supervision

LogicalSupervision is a collection of CheckpointTransitions.

A LogicalSupervision can be seen one graph.

As LogicalSupervision represents a graph, so it is possible to configure the initial and/or the final Checkpoints by referring to those Checkpoints.

A CheckpointTransition has its Source and Target Checkpoint. One Checkpoint can have multiple Transitions - this way it is possible to configure merges and forks in the graph (e.g. from A you can go to B or to C).

![Diagram of Logical Supervision](image)

Figure 8.6: Logical Supervision

8.3.4 Global Supervision

A GlobalSupervision is an overall state of a software subsystem. There can one or a few GlobalSupervisions per Machine. It has the following options:

1. SupervisionCycle: at which cycle the GlobalSupervision and its contained LocalSupervisions are executed (i.e. at which cycle the new state is determined)

2. ExpiredSupervisionCycleTolerance: maximum acceptable amount SupervisionCycles in the global state GLOBAL_STATUS_EXPIRED before it is considered GLOBAL_STATUS_STOPPED.
GlobalSupervision is a "worst-of" of all contained LocalSupervisions. LocalSupervision represents the state of a a group of AliveSupervision, which have the same SupervisionCycle as their parent GlobalSupervisions. It has the following option:

1. FailedSupervisionCyclesTolerance: maximum acceptable amount SupervisionCycles in the local state LOCAL_STATUS_FAILED before it is considered LOCAL_STATUS_EXPIRED.

Note that the option FailedSupervisionCyclesTolerance is used only for AliveSupervision.

There is no fixed relation between SupervisedEntity on one side and LocalSupervision or GlobalSupervision on another side - it is fully configurable.

8.3.5 Arbitration

Arbitration has the following option:

1. ArbitrationCycle: time period at which the Arbitration is performed.

The Arbitration has three parts:

1. Condition: boolean conditions representing if a condition is fulfilled or not
2. LogicalExpression: logical expressions built on Conditions or other LogicalExpressions
3. Rule: it takes the result of one LogicalExpression and it defines the reaction based on it.
One **Condition** is a boolean and it is built by a reference to two elements:

1. **HealthChannel** + **HealthStatus** value or
2. **AliveSupervision** + **LocalSupervision** value or
3. **DeadlineSupervision** + **LocalSupervision** value or
4. **LogicalSupervision** + **LocalSupervision** value or
5. **GlobalSupervision** + **LocalSupervision** value.

Example: condition c1 meaning that "MotorEngine == HH"

One **LogicalExpression** is built on top of **Conditions** or/and other **LogicalExpressions**, connected with **LogicalOperators**. It is a boolean equation, e.g. \( c_1 \) or \( c_2 \). It has the following option:

1. **LogicalOperator** a boolean operator used to connect **Conditions** and/or **LogicalExpressions**

**Rule** has the following option:

1. **RuleInitState** that defines the value before the **Conditions** are available. The **Rule** is considered true (active) if its **Condition** is true.
8.3.6 Determination of Action

DeterminationOfActions is a collection of ActionLists to be performed.

A Rule takes the result of exactly one LogicalExpression and defines the handling of a reaction based on the result of the LogicalExpression:

1. if the LogicalExpression evaluates to true the ActionList referenced in the role TrueActionList will be indicated for execution

2. if the LogicalExpression evaluates to false the ActionList referenced in the role FalseActionList will be indicated for execution

The ActionList collects an ordered list of ActionItems to be executed when the ActionList is executed.

The parameter ActionListExecution of ActionList defines the execution semantics of the indicated action list. It can contains the following values:
1. **triggeredOnChange**: Actions shall only be executed when the evaluation result of the corresponding rule changes

2. **triggeredOnEvaluation**: Actions shall be executed every time the evaluation of the corresponding rule is done

The definition of **ActionItem** is not standardized (marked in blue). It could be e.g.:

1. request to switch to another mode
2. request to re-establish (reenter) the current mode, possibly by doing the reset
3. request to do soft reboot
4. immediate reset by direct invocation of low-level drivers
5. wrong triggering of HW watchdogs, resulting with immediate reset.
